PREFACE TO THE FIRST EDITION.

FORTY-TWO years have elapsed since Sir J. D. Hooker published the first part of his "Handbook of the New Zealand Flora." Although no complete account of the plants of the colony has since been prepared, botanical investigations have been actively and zealously carried on, and a large amount of fresh material obtained. No less than four hundred separate communications or short papers dealing with the botany of New Zealand have been published, and the number of new species proposed is considerably over a thousand. The literature and descriptions of the new species are scattered through the thirty-seven volumes of the "Transactions of the New Zealand Institute" and other publications, some of which are not readily accessible to the majority of workers in the colony. To make satisfactory use of such a mass of unarranged and undigested material is beyond the power of any except a few experts: in any case an attempt to do so would prove both tedious and troublesome. In short, the want of a compendious Flora has long been a serious hindrance to the study of the indigenous vegetation, and a bar to inquiries of any kind connected therewith.

For many years New Zealand botanists hoped that the preparation of a new Flora would be undertaken by the late Mr. T. Kirk. It was known that he had long been collecting material for such a work. His many journeys, extending from the North Cape to the Auckland and Campbell Islands, had given him an unrivalled personal acquaintance with the vegetation, while his numerous writings afforded abundant proof of widespread knowledge, and of accurate and careful botanical research. Under such circumstances, the announcement made in 1894 that he had been engaged by the New Zealand Government to prepare a "Students' Flora of New Zealand" was received with general approval. And when his death occurred in 1897 it was a disappointment to find that barely two-fifths of his task had been completed. This portion has since been printed by the Government, and its value intensifies the regret that the author did not live to complete the work for which he had made so much preparation, and for which he possessed so many undoubted qualifications.

The publication of the fragment left by Mr. Kirk made the want of a complete Flora still more apparent, and in April, 1900, the Government was pleased to entrust me with the preparation of such a work. While allowed full freedom of action in all details, I was instructed to follow the

general plan adopted in Sir J. D. Hooker's Handbook, which, as is well known, was based upon that recommended many years ago by Sir W. J. Hooker for a uniform series of Floras of all the British colonies. With the view of keeping the work within the compass of one volume of portable size, I was further directed to confine it to the indigenous plants, thus departing from the plan followed by Kirk, who included all well-established naturalized plants, distinguishing them from the native species by a difference in the type.

The "Manual of the New Zealand Flora," which is the title adopted for the present work, is intended to comprise within a reasonable compass full descriptions of the whole of the indigenous flowering-plants and ferns found within the limits of the Colony of New Zealand, including not only the two main Islands, but also the outlying groups of the Kermadec Islands, the Chatham Islands, the Auckland and Campbell Islands, Antipodes Island, &c. I have also included Macquarie Island, for although it is politically an appanage of Tasmania, it is more closely allied in its flora and fauna to the Auckland and Campbell Islands than to any other land. In addition to the descriptions, I have given as fully as possible the geographical and altitudinal range of each species within the colony; and, in the case of non-endemic plants, a short statement of their range in other countries. I have also inserted, in a concise form, such general information, whether economic or scientific, as appeared to be of sufficient value. Believing that the main object of a Flora is to afford a ready means of determining the name of any species for the purpose of ulterior study, I have endeavoured so to frame the descriptive matter as to facilitate the work of identification as much as possible. I have therefore prefixed to each order and each genus analytical keys in which the salient characters of the genera and species are contrasted. With respect to the descriptions themselves, they are in almost all cases original, and have been based on the actual examination of living or dried specimens, usually both. After their preparation they were compared with those of my predecessors, and particularly with those of Hooker and Kirk, when any additions or alterations that appeared to be necessary were made. With regard to the citation of previous authors, I have as a rule considered it unnecessary to do more than quote the publications that deal solely or mainly with New Zealand botany, such as Forster's Prodromus, A. Richard's Flora, Cunningham's Precursor, Raoul's Choix, and the works of Hooker and Kirk. Had I given references to general works on botany or to special monographs the bulk of this work would have been greatly increased without sufficient corresponding advantage. I have, however, quoted the publication in which the species under consideration was first described; and, in the case of those plants which extend to Australia or Tasmania, I have usually given a reference to Bentham's "Flora Australiensis" or Hooker's "Flora of Tasmania."

The synonymy I have treated in a similar manner. As far as the information at my command would permit, I have quoted all published names of endemic New Zealand plants, and all names founded upon New Zealand specimens. Further quotation would, in my opinion, be neither necessary nor expedient for the purposes of this work.

Every botanist who prepares a Flora starts from the standpoint reached by his predecessors in the same field. In the subjoined history of botanical discovery in New Zealand I have endeavoured to give a sketch of the labours of all those who have investigated the botany of the colony, either as authors or collectors, and who have thus assisted in providing material for future study and research. But, in addition, it is advisable to briefly mention the chief material upon which the present work is founded. At the outset I must state that I have relied very largely upon my own notes and observations, formed during thirty-five years' continuous study of the flora, and upon my herbarium, which I believe to be the largest and most complete formed by individual effort within the colony.

I am indebted to the Education Department for the loan of that portion of the herbarium of the late Mr. Kirk which after his death was purchased by the New Zealand Government. Although comprising only a small part of the collections formed by this active and enterprising botanist, it nevertheless includes excellent and well-selected specimens of most of the species of the flora, including the types of the new species described by him, and has consequently proved an important aid to me. It is to be regretted that Mr. Kirk's botanical papers and other manuscripts, none of which I have seen, were not included in this purchase.

The Education Department has also placed at my service a set of the plants collected by Banks and Solander during Cook's first voyage, a transcript of Solander's manuscript descriptions, and a set of impressions from the copper plates prepared by Sir Joseph Banks to illustrate the descriptions. All these were presented to the Government a few years ago by the Trustees of the British Museum, and form a unique and valuable addition to the public collections of the colony.

I am indebted to my friend Mr. D. Petrie, well known for his successful exploration in the Otago District, for the very valuable and important aid afforded by the study of his herbarium, which he has loaned to me in instalments during the progress of this work. It is specially rich in specimens of the rarer alpine plants of Otago, which, as a rule, are very poorly represented in other collections.

The herbarium of the late Mr. Colenso has been lent to me by Mr. H. Hill, one of the trustees under his will. It contains a large amount of material, collected at various times between the years 1840 and 1898, but is to a great extent unarranged and unclassified. Fortunately,

however, it includes named specimens of many of the supposed "new species" described by him during the last fifteen years of his life, and has thus enabled me to come to more certain conclusions respecting them than would otherwise have been the case.

The private herbarium of the late Mr. John Buchanan has been forwarded for my inspection by the Council of the Otago University, to which body it was bequeathed. Although but a fragment of the collections he formed during his lifetime, it has been of considerable service, as it includes the types of most of his new species, and the drawings and analyses prepared for his work on the New Zealand grasses.

My friend Dr. Cockayne has supplied me with much valuable information, and a considerable amount of interesting material from the Southern Alps, the Chatham Islands, and other localities explored by him. Many of his specimens have been of particular value, from being specially selected to show the range and trend of variation in some of the more variable species of the flora.

The Right Rev. W. L. Williams, Bishop of Waiapu, has placed me under many obligations by regularly forwarding specimens collected by him in the East Cape and Hawke's Bay districts, and by his invaluable help in compiling the list of Maori plant-names given in the Appendix.

Mr. W. Townson, of Westport, has for many years supplied me with numerous sets of specimens, both fresh and dried, collected by him in the south-west portion of the Nelson Provincial District, and often obtained from out-of-the-way localities and at considerable altitudes. So little was previously known respecting the botany of this portion of the colony that his collections and notes have been of great service to me.

I am indebted to Mr. A. Hamilton for the loan of his extensive collection of the ferns of the colony. This is not only unusually complete and well arranged, but also contains many specimens of crested and other abnormal varieties.

I have also to record my thanks to Sir James Hector, Mr. J. D. Enys, Mr. G. M. Thomson, Mr. H. Hill, Mr. Justice Chapman, Mr. Percy Smith, Mr. H. J. Matthews, Mr. F. R. Gibbs, Mr. J. H. Macmahon, Mr. J. Adams, Mr. R. H. Matthews, Mr. H. Carse, Mr. Elsdon Best, Mr. R. J. Kingsley, Rev. F. E. Spencer, Mr. H. C. Field, Mr. J. Rutland, Mr. F. A. D. Cox, Mr. J. Hall, Mr. H. H. Travers, Mr. J. B. Simpson, and several others, for the material assistance they have rendered me.

Turning from New Zealand, I have now to express my gratitude to several friends and correspondents in Europe. First of all, I wish to tender my special thanks to Sir J. D. Hooker, who during a correspondence extending over thirty-five years has been at all times ready to give me the benefit of his wide knowledge and experience, and who has evinced

the greatest possible interest in the inception and progress of this work. My thanks are also due to Sir W. T. Thistleton-Dyer, the present Director of Kew, for his kindness in granting facilities for the comparison of my specimens with the types preserved in the Kew Herbarium, and for other valuable assistance; also to Mr. W. B. Hemsley, the Assistant Director, who has given me much helpful aid with the greatest readiness and kindness; and to Mr. N. E. Brown, who was specially instructed by the Director to make a comparison of my specimens with the types of the species in *Veronica*, *Gentiana*, *Myosotis*, and other genera, and whose report on the subject has been invaluable to me. I am also greatly indebted to Mr. C. B. Clarke for his unwearied kindness in supplying me with information and critical notes respecting the New Zealand *Cyperaceae*, and for furnishing me with a list of the synonymy of the species. Pastor G. Kukenthal, of Grub, near Coburg, has also contributed valuable notes respecting the New Zealand species of *Carex* and *Uncinia*. Finally, I am under many obligations to Professor E. Hackel, of Graz, Austria, for undertaking a critical examination of the whole of the New Zealand grasses, and for furnishing me with a series of very full and complete notes, with permission to use the same for the purposes of this work.

The elimination of the naturalized species from the present work, although absolutely necessary to keep it within the limits of a single volume, will not be altogether satisfactory to the student. A beginner cannot be expected to distinguish between the indigenous and introduced species, especially when it is remembered that in several districts the latter now constitute the larger portion of the flora, and that there is no part of the country, however remote, into which some plants of foreign origin have not penetrated. Altogether, over six hundred species, or nearly one-half the number of the indigenous flowering-plants, have succeeded in establishing themselves. I am not without hopes that I may be enabled to prepare a supplementary volume containing concise but sufficient descriptions of the foreign element of the flora; for this alone will remove the inconvenience resulting from the want of a ready means of determining all the plants which a student may observe in any district. In the meantime, I have given in the Appendix a nominal list of all well-established naturalized plants, with references to books in which descriptions of them can be found. As most of the species are of European origin, I would recommend the student to provide himself with a copy of Hooker's "Students' Flora of the British Islands," or some similar work, and to use it in conjunction with this publication.

It is not to be expected that a work containing descriptions of over 1,550 species of plants can be prepared without the occurrence of errors and imperfections, and for these I must ask the indulgence of the reader. One serious disadvantage under which I have laboured, and which I share

in common with all colonial botanists, is the impossibility of examining those European herbaria in which the types of so many of the published species are deposited; and consequently mistakes may have been made in the identification of the species, especially in genera like *Veronica*, *Gentiana*, *Myosotis*, &c. But I trust that the number of such errors is not large. Their detection may be safely left to future workers.

A few statistics respecting the extent and composition of the flora may be of interest. The total number of species described, including a few additions given in the Appendix, is 1,571, of which 1,415 are phaenogams, and 156 vascular cryptogams. These are contained in 382 genera, distributed in 97 orders. The average number of species to each order is slightly over 16; the average number of species to each genus rather more than 4. The orders containing more than 24 species are as under:—

Compositae	221	Ranunculaceae	50
Filices	138	Rubiaceae	47
Cyperaceae	119	Epacrideae	31
Scrophularineae	113	Onagrarieae	31
Gamineae	113	Leguminosae	26
Umbelliferae	62	Juncaceae	25
Orchideae	57	Boraginaceae	25

The *Compositae* thus constitute one-seventh of the whole flora, an unusually high proportion. The genera containing 20 species or more are—

Veronica	84	Senecio	30
Carex	54	Epilobium	28
Celmisia	43	Poa	25
Coprosma	40	Myosotis	23
Ranunculus	38	Hymenophyllum	20
Olearia	35		

Of the total number of species (1,571) no fewer than 1,143, or nearly three-quarters of the entire flora, are peculiar to the colony. With respect to the 428 species which are found elsewhere, 366 extend to Australia, and 108 to South America. Coming to the local distribution of the species, 789 are found in both the North and South Islands, 219 occur in the North Island but have not yet been detected in the South Island, while 456 species known to occur in the South Island have not been collected in the North Island. No fewer than 23 species are found in the Kermadec Islands but not in any other portion of the colony; 25 in the Chatham Islands; 10 in Stewart Island; and 48 in the outlying islands to the south of New Zealand, including in the term the Auckland and Campbell Islands, Antipodes Island, and Macquarie Island.

It now only remains for me to express my grateful thanks to the Education Department, under whose auspices the work has been prepared, for the readiness with which it has co-operated with me in endeavouring to render it as complete and reliable as possible. In this connection I would specially mention the Right Hon. R. J. Seddon, Minister of Education, and Mr. G. Hogben, M.A., the Inspector-General of Schools. My thanks are also due to the Council of the Auckland Institute and Museum for kindly allowing me to engage a substitute to perform a portion of my duties at the Museum during the progress of the work. Finally, I have to express my obligations to the Government Printer for the assiduous care with which he has attended to the passage of the work through the press.

Auckland, January, 1906.

PREFACE TO THE SECOND EDITION.

THE present edition of the "Manual of the New Zealand Flora" has, unfortunately, not received the final revision of the author. Mr. Cheeseman died at Auckland on the 15th October, 1923. At that date he had completed the manuscript of the main portion of the work, the synoptical key to the families, the list of Maori names, and the glossary. He was working at the list of introduced plants, about half of which had been completed. The latter half of this list I have completed from the notes left by Mr. Cheeseman and from his published papers. I have made no attempt to revise it in accordance with all the information published since the appearance of the first edition of the Manual, as I did not wish to impose my own views on any portion of the work which would bear his name as author.

For a similar reason I have not altered anything in the main portion of the flora, other than correcting obvious errors and revising references for the sake of consistency. The spelling of the generic and specific names and use of capital letters stands, therefore, as Mr. Cheeseman left them. The original preface and the section dealing with the history of botanical discovery in New Zealand had not been altered by Mr. Cheeseman, and are here reprinted in their original form. The present edition, therefore, is the work of Mr. Cheeseman as he left it at the time of his death, with the addition of the following portions, namely: The present preface, review of botanical work from 1905 to 1924, and the list of the published works of Mr. Cheeseman, all of which I have myself prepared, while Mr. Elsdon Best has kindly supplied a further list of Maori names of plants, and these have been included in the general list and there duly acknowledged.

A considerable portion of the Manual had been finally printed off before I took over the work of correcting the proofs, and a certain amount of inconsistency in the method of quoting authors and references to literature has resulted from the practice of printing off each sheet separately and immediately breaking up the type. In that portion of the work which I have corrected I have, when the original paper was accessible to me, quoted the title of the volume and the page number for each reference. Mr. Cheeseman followed various practices, in several cases quoting the number of the species and not the page, or the title of the paper instead of the journal in which it appears. Thus Cunningham's paper appears as *Precur.*, but this is merely an abbreviation of the title of the paper, and as I have not had access to it I have let the references as quoted by Mr. Cheeseman stand.

Errors are unavoidable in a volume of the size and nature of a flora, and where the work passes from one person to another detection of such is made less easy. It is hoped, however, that those that appear in the present edition of the Manual are not many and are obvious or unimportant omissions or misspellings. No doubt they will be found mainly in the references following the descriptions of the species.

In the preface to the first edition Mr. Cheeseman gave some figures relating to the extent and composition of the flora. Similar information based on the present edition has therefore been compiled and is given in the succeeding paragraphs.

The total number of species described is 1,763, or 192 more than in the first edition. These are distributed over 390 genera included in 104 families. But of these, Filices, treated by Mr. Cheeseman as a single family, is now generally considered to be a class of which the New Zealand species belong to 9 families. The average number of species to a family is 17, and of species in a genus is 4·5. These figures are higher than those quoted by Mr. Cheeseman, the difference being due to the number of new species described since the first edition, especially in the larger genera of flowering-plants. The species consist of 159 Pteridophytes, 20 Gymnosperms, and 1,584 Angiosperms, of which 400 are Monocotyledons and 1,184 Dicotyledons.

The families containing more than 24 species are as under:—

Compositae	261	Onagraceae	40
Filices	141	Epacridaceae	33
Scrophulariaceae	138	Boraginaceae	33
Cyperaceae	123	Leguminosae	32
Gramineae	123	Juncaceae	27
Umbelliferae	79	Liliaceae	27
Orchidaceae	66	Gentianaceae	26
Ranunculaceae	53	Cruciferae	25
Rubiaceae	52		

The genera containing 20 species or more are—

Veronica	103	Aciphylla	25
Celmisia	58	Gentiana	24
Carex	55	Pittosporum	23
Coprosma	44	Cotula	23
Olearia	42	Raoulia	22
Ranunculus	41	Carmichaelia	21
Epilobium	37	Hymenophyllum	20
Senecio	35	Anisotome	20
Myosotis	31	Dracophyllum	20
Poa	28		

Of the 1,763 species comprising the indigenous vascular flora of New Zealand, 1,329, or 75·4 per cent., are confined to the Dominion. Of the 434 species which are found elsewhere, 369 extend to Australia and 112 to temperate South America. The last figure includes 30 species found in temperate South America and New Zealand but not in Australia. Of the 369 Australian species, 252 do not extend to South America at all, 82 extend to temperate South America, some being tropical as well, while 35 extend to tropical but not to temperate South America. There are 35 species of vascular plants found in New Zealand and some country other than Australia or South America.

The local distribution of the species is as follows: Found in both the main Islands, 847 species; found in the North Island but not in the South Island, 250 species (three of these also found in Stewart Island); found in the South Island but not in the North Island, 528 species. The outlying islands contain many plants not occurring in other portions of the Dominion, though some may extend to Australia, South America, or other countries. In the Kermadec Islands are 25 species; in the Chatham Islands, 33 species (including 1 species also found in the Auckland Islands); in Stewart Island, 22 species; in the Subantarctic Islands, including The Snares, Auckland, Campbell, and Antipodes Islands, 56 species. (The localities of two species described in the present edition are unknown.)

In correcting the proofs of Mr. Cheeseman's Manual the work has been mainly to ensure that the manuscript has been printed correctly, hence I have come in contact mostly with the Government Printer and his staff, and particularly with the Superintendent, to whom I tender my sincere thanks for many obliging acts. My thanks are also due to Dr. L. Cockayne and Professor H. B. Kirk for advice in selecting the matter which I have contributed, and to Mr. J. H. Maiden, Director of the Sydney Botanic Gardens, for supplying dates for many references which were not accessible to me.

I should also mention that shortly after Mr. Cheeseman died the matter of carrying on the work of seeing the Manual through the Press was referred to the Board of Science and Art, and by its decision I was selected. I have felt fully the responsibility of the honour thus bestowed on me. The task has proved somewhat long and arduous, but I trust that the errors which I have failed to detect will not detract from the value or appearance of Mr. Cheeseman's work.

W. R. B. OLIVER.

A HISTORY OF BOTANICAL DISCOVERY IN NEW ZEALAND.

(Reprinted from the First Edition.)

The history of botanical discovery in New Zealand falls naturally and conveniently into two periods of almost equal duration. The first commences with the year 1769, in which Cook made his first visit, and closes with the establishment of British supremacy and the commencement of systematic colonization in 1840. During the seventy-one years comprised between these dates many voyages of discovery or survey in the South Pacific were undertaken by the British, French, or American Governments, during most of which New Zealand was visited. And, as naturalists or collectors were usually attached to these expeditions, it was through them that our first knowledge of the flora was obtained. During the same series of years several travellers of scientific attainments also visited New Zealand, such as the two Cunninghams, Dieffenbach, Bidwill, &c., all of whom formed collections of considerable importance. This period may therefore be appropriately called the period of investigation by visitors from abroad. That extending from 1840 to the present time can be just as correctly styled the period of investigation by naturalists resident in the colony.

Commencing with the voyages, the first in order of time, as well as in degree of importance, is Cook's first visit (1769–1770). For full details concerning this celebrated expedition, which has been well said "to have been the most momentous voyage of discovery that has ever taken place, for it practically gave birth to the great Australian colonies," I must refer the reader to Hawkesworth's "Cook's Voyages," Wharton's transcript of Cook's journal, and Hooker's "Journal of Sir Joseph Banks." For the purposes of this work the following sketch will be sufficient. Cook's ship, the "Endeavour," left England on the 26th July, 1768. For that period, she was unusually well equipped for scientific work. Sir Joseph Banks, one of the leading naturalists of his time, and a man of much influence and ample fortune, volunteered to accompany the expedition. At his own expense he provided the requisites for making collections in every department of natural science, and engaged Dr. Solander, four draughtsmen or artists, and a staff of servants to accompany him. The cost to Banks of these preparations has been estimated at £10,000. After rounding Cape Horn, and after a stay of nearly four months at Tahiti and other islands of the Society Group, Cook struck south-westwards across the Pacific. On Friday, the 6th October, 1769, he first sighted New Zealand, and at once stood in for the land. Delayed by calms and baffling winds, it was not until the afternoon of Sunday, the 8th October, that he anchored on the north-west side of a deep bay, to which he afterwards gave the name of Poverty Bay, and almost directly opposite the present town of Gisborne. Cook immediately landed, accompanied by Banks and Solander, but an unfortunate skirmish took place with the Maoris, one of whom was shot, and the party returned to the ship. The next morning a landing was made

in greater force, and some intercourse took place with the Maoris through the medium of a Tahitian interpreter. Their behaviour, however, was so threatening that it became necessary to fire upon them, and another man was killed and several wounded. Discouraged by this reception Cook once more re-embarked. The following morning another landing was effected, and Cook, together with Banks and Solander, strolled some little distance up the right bank of the Waikanae River. But the Natives again became troublesome, and a retreat had to be made to the landing-place. Seeing no hope of establishing a pacific intercourse, Cook returned to his vessel, and at daylight the following morning left the bay. Under the circumstances narrated above, it is obvious that little botanizing could be done. Banks, in his journal, laments that "We took leave of Poverty Bay, as we named it, with not above forty species of plants in our boxes, which is not to be wondered at, as we were so little ashore, and always upon the same spot. The only time when we wandered about a mile from the boats was upon a swamp, where not more than three species of plants were found."

After leaving Poverty Bay Cook followed the coast southwards, successively passing Table Cape, Portland Island, Hawke's Bay, and Cape Kidnappers, but nowhere making any attempt to land. On the 17th October, when off Cape Turnagain, he determined to return to the northwards, giving as a reason that there was "no likelyhood of meeting with a Harbour, and the face of the Country Visibly altering for the worse." On the 19th he repassed Poverty Bay, and on the 20th anchored in Anaura Bay, which he called "Tegadoo." Here the reception given by the Natives was all that could be desired, and Cook consequently remained until daylight on the 22nd, for the purpose, as he states, of giving "Mr. Banks an opportunity to Collect a little of the Produce of the Country." Banks, in his journal, says, "We ranged all about the bay, and were well repaid by finding many plants and shooting some most beautiful birds." Further on, he gives a description of the Maori cultivations, in which were planted "sweet potatos, cocos, and a plant of the cucumber kind," doubtless referring to the kumara, taro, and hue. Dr. Solander, in his manuscript volume of descriptions, presently to be referred to, enumerates ninety-eight species of plants as having been collected at "Tigadu." Among these were the first specimens of the beautiful *Clianthus puniceus*, which was found cultivated by the Natives near their dwellings.

On taking his departure from Anaura, Cook at first stood to the northwards, but the wind being unfavourable he determined to put into Tolaga Bay, where the Natives had informed him wood and water could easily be obtained for his ship. On the morning of the 23rd he accordingly anchored about a mile from a small cove just inside the southern point of the bay. Here a stay was made until the 30th October. The Natives were friendly and obliging, and an ample supply of wood and water was obtained. Both Banks and Solander passed most of their time on shore, and an excellent collection of plants was formed. With respect to the vegetation, Cook remarks, "The Tops and ridges of the Hills are for the most part barren, at least little grows on them but fern; but the Valleys and sides of many of the Hills were luxuriously clothed with woods and Verdure and little Plantations of the Natives lying dispers'd up and down the Country. We found in the Woods, Trees of above 20 different sorts; Specimens of each I took on board, as all of them were unknown to any of us. The Tree which we cut for firing was something like Maple and

yielded a whitish Gum. There was another sort of a deep Yellow which we imagin'd might prove useful in dyeing. We likewise found one Cabage Tree which we cut down for the sake of the cabage. The Country abounds with a great Number of Plants, and the woods with as great a variety of beautiful birds, many of them unknown to us." Altogether, Tolaga Bay appears to have left a favourable impression on the " Endeavour's " people. From the localities cited in Solander's manuscripts, it appears that about 160 species of plants were collected.

Leaving Tolaga Bay on the 30th October Cook made sail to the northwards. On the following day he rounded the East Cape, and passing Cape Runaway and White Island (which was evidently quiescent at that time) he coasted along the shores of the Bay of Plenty, having occasional intercourse with those Maoris who came off to him in their canoes, but making no attempt to land. On the 3rd November he was abreast of Tauranga, and on the 4th reached the entrance of Mercury Bay. Finding in this locality a secure harbour with plenty of wood and water, and being anxious to observe the transit of Mercury, which was to take place on the 9th, Cook brought his vessel to an anchor. During a stay of eleven days many plants were collected, figured, and described, the total number, reckoning from Solander's manuscripts, being 213. Among those which had not been previously observed was the Mangrove (*Avicennia officinalis*), which occurred in such abundance along the sides of the Whitianga River that Cook gave it the name of the " River of Mangroves." Through a curious misapprehension he states that the mangroves " produce a resinous substance very much like Rosin. . . . . We found it, at first, in small Lumps upon the Sea Beach, but afterwards found it sticking to the Mangrove Trees, and by that means found out from whence it came." The resinous substance was no doubt the now well-known kauri-gum, pieces of which are often drifted along tidal streams, and are not infrequently detained among the roots or lower branches of the mangrove. The kauri-tree itself does not seem to have been observed, either by Cook or by Banks and Solander, although common enough on the hills overlooking Mercury Bay. Probably they did not venture far enough from the coast to reach it.

After leaving Mercury Bay Cook continued to follow the coast-line, and, rounding Cape Colville, entered the Hauraki Gulf. Here he found himself surrounded by islands, and, not wishing to lose sight of the mainland, kept close under the western side of the Coromandel Peninsula. A short sail brought him to the entrance of the Thames River, where he anchored, almost directly abreast of the position where the Town of Thames now stands. On the following day, the 21st November, accompanied by Banks and Solander, he made a boat voyage up the Thames River for a distance of twelve or fourteen miles. A landing was effected on the west side of the river for the purpose of examining the kahikatea forest which still clothes its banks, and which had attracted Cook's attention at his anchorage. Describing the trees, he says, " We had not gone a hundred yards into the woods before we found a Tree that girted 19 feet 8 inches, 6 feet above the ground, and having a Quadrant with me, I found its length from the root to the first branch to be 89 feet; it was as streight as an Arrow, and Taper'd but very little in proportion to its length, so that I judged that there was 356 Solid feet of timber in this Tree, clear of the branches. We saw many others of the same sort, several of which were Taller than the one we measured, and all of them

very stout; there were likewise many other sorts of very Stout Timber Trees, all of them wholy unknown to any of us. We brought away a few specimens, and at 3 o'Clock we embarqued in order to return." It is somewhat distressing to state that the historic tree mentioned above, after surviving one hundred and thirty years with unimpaired vitality, was wantonly cut down only a few years ago.

From the Thames River Cook's course was directed to Cape Rodney, and from thence northwards to Cape Brett, which was reached on the 27th November. Here contrary winds were met with, and it was not until the 29th that the cape was weathered, and an anchorage found in the Bay of Islands, where the "Endeavour" remained until the 5th December. During this time visits were made to several of the islands in the bay, and to the mainland; but as it was impossible to go far from the coast, along which the vegetation was by no means varied, not many plants were collected, only seventy-seven being credited to the locality in Solander's manuscripts.

Leaving the Bay of Islands, Cook continued his survey of the coast to the North Cape, where he met with fierce and prolonged gales of such exceptional character that three weeks were occupied in rounding it. He then proceeded southwards along the western coast, but its dangerously open character prevented him from making a close approach. He consequently failed to observe any of the harbours — Hokianga, Kaipara, Manukau, Kawhia, &c.—and, as no canoes were seen, there was no intercourse with the inhabitants. He passed Mount Egmont on the 13th January, entered Cook Strait on the 15th, and on the 16th anchored in Queen Charlotte Sound, in the northern portion of the South Island. In this locality he made a stay of three weeks, taking advantage of his visit to careen and clean his ship, to lay in a stock of wood and water, and to give his crew the welcome change of a diet of fresh fish and green vegetables. He remarks that Queen Charlotte Sound "is a collection of some of the finest harbours in the world," and that "the Cove in which we lay, called Ship Cove, is not inferior to any in the Sound, both in point of Security and other Conveniences." He also says that the land "consists wholly of high hills and deep Valleys, well stored with a variety of excellent Timber, fit for all purposes except Ship's Masts, for which use it is too hard and heavy." The collection of plants made was larger than that formed in any other locality, numbering 220 species.

Taking his departure from Queen Charlotte Sound on the 7th February, Cook first took a run northwards to Cape Turnagain, thus completing his survey of the North Island. He then turned to the south, passing down the east coast of the South Island. On the 17th February he rounded Banks Peninsula, which he took to be an island; on the 25th February he was off Cape Saunders; and on the 10th March he was abreast of the south end of Stewart Island, which he assumed to be a peninsula connected with the mainland by a narrow neck. On the 13th he passed the entrance to Dusky Sound, from whence he followed the western coast northwards, reaching Cape Farewell on the 24th March, and thus completing the circumnavigation of the South Island. On the 27th he put into Admiralty Bay, to the west of Queen Charlotte Sound, for the purpose of again renewing his stock of wood and water, and on the 31st he left New Zealand, steering a course for the east coast of Australia.

In 1771 Cook returned to England. The natural-history collections, which were the property of Sir Joseph Banks, contained a large amount

of material; but no work has ever been published treating of them as a whole. The plants had for the most part been fully described by Solander at the time of collection, and coloured drawings prepared of many of the species. Little additional labour was therefore required to prepare the results for publication. Evidently Banks intended that this should be done, for at his own expense he had 700 plates engraved on copper, and Solander's manuscript descriptions were revised and systematically arranged. The New Zealand portion, which was entitled "Primitiae Florae Novae-Zealandiae," contained descriptions of nearly 360 species, illustrated by over 200 plates, and was practically ready for the press. Why it was not actually published is by no means clear, but the suggestion has been made that publication was at first delayed by the preparations made by Banks and Solander to accompany Cook in his second voyage, a project which was ultimately abandoned; and that a more serious interruption was caused by Solander's somewhat sudden death in 1782. After his companion's decease Banks became more and more occupied with his duties as President of the Royal Society, and as an organizer and promoter of scientific research, and the idea of publication appears to have been abandoned. As stated in the preface, a typewritten copy of Solander's descriptions and a set of impressions from the plates have been liberally furnished by the Trustees of the British Museum for use in the preparation of this work. Of their scientific value I cannot speak too highly; and it is a matter for regret that they were not presented to the world 125 years ago. It is, however, some satisfaction to know that the botanical results of the whole voyage are now, after this long delay, being issued under the auspices of the British Museum, and under the careful editing of Mr. Britten.

On the 9th April, 1772, Cook left England for his second voyage, the expedition consisting of two ships, the "Resolution" under his own command, and the "Adventure" under that of Captain Furneaux. John Reinhold Forster and his son George Forster, both well-known botanists, accompanied him in the capacity of naturalists, and were joined at the Cape of Good Hope by Dr. Sparrmann, also a botanist of repute, and a former pupil of Linnaeus. After several months had been spent in an unsuccessful search for a southern continent Cook made sail for the south of New Zealand. During the voyage he was accidently separated from the "Adventure" and, failing to rejoin her, put into Dusky Sound, the entrance to which had been noticed in his first voyage. He remained there from the 26th March, 1773, to the 1st May, mainly for the purpose of refitting, and to give his crew a rest after the months of incessant buffeting experienced in high southern latitudes. During his stay many boat voyages were made to various parts of the Sound, and a careful survey was made of it. The two Forsters devoted much of their time to botanizing, but their collections were by no means so large as might have been expected, considering what a productive locality Dusky Sound has proved to be in later years. Among the plants gathered were *Olearia operina*, *Celmisia holosericea*, *Gentiana saxosa* and *G. montana*, and *Cordyline indivisa*.

From Dusky Sound the "Resolution" proceeded northwards to Queen Charlotte Sound, which was reached on the 18th May. Here she rejoined the "Adventure," which had arrived on the 7th April. Both vessels left on the 7th June, in the first place for a cruise to the south-east of New Zealand, in further search for a southern continent, and then for eastern Polynesia. In October Cook again directed his course to New Zealand. Making the coast of the North Island near Table Cape, he steered to the

south, stopping near Cape Kidnappers to give pigs and fowls to some Natives that came off to his ship. Up to this time the two vessels had been in company, but off Cape Palliser exceptionally severe weather was encountered, and they separated. The "Resolution" proceeded to Queen Charlotte Sound, which had been appointed a place of rendezvous, and remained there waiting for her consort from the 3rd November to the 25th, when Cook left for a cruise to the Antarctic Ocean. Five days after his departure the "Adventure" arrived, and remained until the 23rd December. During this stay an unfortunate dispute arose with the Maoris, which led to the massacre of a boat's crew of ten men. After a year's explorations in various parts of the Pacific Cook once more returned to New Zealand, anchoring in his favourite resort, Queen Charlotte Sound, on the 19th October, 1774. His stay was but short, and on the 10th November he left on his return voyage, reaching Plymouth on the 30th July, 1775.

From the above sketch it will be seen that the only localities botanized in during Cook's second voyage were Queen Charlotte Sound, which had already been explored by Banks and Solander, and Dusky Sound. But a much longer period was spent in harbour and on shore than during the previous voyage, and the collections ought to have been quite as extensive. Instead of this, they were much smaller, the total number of flowering-plants and ferns not exceeding 180 species. Sets of these were distributed to several public and private herbaria—unfortunately, in a somewhat careless manner as regards the nomenclature, thus causing many mistakes and much confusion. Within twelve months after their return the two Forsters conjointly issued a work entitled "Characteres Genera Plantarum," in which seventy-five new genera were shortly described and illustrated, thirty-one of them being from New Zealand. The book is interesting on account of containing the first published descriptions of New Zealand plants, but otherwise is most disappointing. The descriptions are short and meagre, and the illustrations so badly executed as to be practically useless. In 1786 George Forster published his "Florulae Insularum Australium Prodromus," which contains diagnoses of 594 species, about 170 of which have New Zealand assigned as a habitat. As in the preceding work, the descriptions are short and unsatisfactory, and usually quite insufficient for the proper identification of the species. In the same year he also issued a little tract entitled "De Plantis Esculentis Insularum Oceani Australis Commentatio Botanica," which includes full descriptions and much curious information respecting the esculent plants, fifty-four in number, observed during the voyage, fourteen of which were from New Zealand. These three publications, together with a short essay, "De Plantis Magellanicis et Atlanticis," which contains no reference to New Zealand, appear to be the whole of the matter written by the Forsters respecting the botany of Cook's second voyage.

Cook's third and last voyage can be passed over with a few words. He left England on the 12th July, 1776, and after visiting the Cape of Good Hope, Kerguelen Island, and Tasmania, reached his favourite anchorage in Queen Charlotte Sound on the 12th February, 1777, this being his fifth visit to the locality. His stay was brief, and on the 25th February he finally left New Zealand. Cook's surgeon, Mr. W. Anderson, had some knowledge of natural history, and his description of Queen Charlotte Sound, printed in Hawkesworth's "Cook's Third Voyage" (vol. i, p. 145), contains an excellent account of the vegetation. His collections, however, were small and unimportant.

In 1791 Captain Vancouver, in command of the "Discovery," accompanied by Captain Broughton in the "Chatham," visited Dusky Sound, making a stay of nearly three weeks. The surgeon to the expedition, Archibald Menzies, devoted himself to the higher cryptogams, and made a large collection of ferns, mosses, and *Hepaticae*. Many of his specimens were figured by Sir W. J. Hooker in the "Musci Exotici" or "Icones Filicum," together with a few flowering-plants in the "Icones Plantarum." A set of his collections is in the British Museum Herbarium, and another at Kew.

The first of the French voyages of discovery to touch at New Zealand was that of Captain De Surville, in the "Saint Jean Baptiste." De Surville arrived off Doubtless Bay in December, 1769, only three days after Cook had passed the same locality on his way to the North Cape. He remained three weeks at anchor in Mangonui Harbour, and was most hospitably treated by the Maoris, a hospitality which he returned by burning one of their villages and destroying their canoes, apparently because he suspected them of stealing a boat which had accidentally got adrift. I cannot learn that any natural-history collections were made during this visit.

In 1772 an expedition consisting of two vessels, the "Mascarin" and the "Marquis de Castries," under the command of Marion du Fresne and Duclesmeur, arrived off Cape Egmont. Proceeding northwards, and failing to find a harbour, the ships rounded the North Cape, and eventually anchored in the Bay of Islands, where a stay of over two months was made. Marion and his people were welcomed with such apparent cordiality by the Maoris that no suspicions of treacherous conduct were aroused. They were thus quite unprepared for the sudden attack which was made upon them, and which resulted, as is well known, in the massacre of Marion and nearly thirty of his crew. A graphic account of this unfortunate incident is given in the journal of Crozet, upon whom the command devolved after Marion's death. The same journal contains and excellent sketch of the natural productions of the country, in which many references are made to the vegetation; but, as in De Surville's expedition, no collections were made.

In 1824 the surveying corvette "Coquille," under the command of Captain Duperrey, arrived at the Bay of Islands, and remained for nearly a fortnight. Two naturalists were on board, Lieutenant D'Urville (afterwards Admiral D'Urville), an ardent botanical collector, and M. Lesson, both of whom made collections of some extent. In the beginning of 1827 D'Urville revisited New Zealand in command of the same vessel, renamed the "Astrolabe." He was again accompanied by Lesson, and also by Quoy and Gaimard as zoologists. First sighting the coast of the South Island near Greymouth, he proceeded northwards, and, rounding Cape Farewell, entered Cook Strait. A secure anchorage was found on the west side of Tasman Bay, between the mouth of the Motueka River and Separation Point, in which he remained for a week, forming important collections. He then crossed to the east side of Tasman Bay, and discovered the strait separating D'Urville Island from the mainland, known to this day as "the French Pass." Several days were occupied in surveying this passage, during which time both the botanical and zoological collections were added to. D'Urville then sailed through Cook Strait, and followed the east coast of the North Island to Tolaga Bay, where a brief stay was made. Continuing his voyage, he rounded the East Cape, crossed the Bay of Plenty,

and, passing to the north of the Great Barrier Island, arrived at Whangarei Heads, where he remained for two or three days. Turning southwards, he passed Cape Rodney and Tiritiri Island, and anchored at the entrance to Auckland Harbour, of which little was known at that time. He landed on both the northern and southern banks of the Waitemata, and, having sent a boat up the Tamaki River as far as the present township of Otahuhu, some of his men were guided by the Maoris across the narrow isthmus to the head of the Manukau Harbour. D'Urville left Auckland Harbour by the Waiheke Channel, passed between the Great and Little Barrier Islands, and after a cruise to the North Cape returned to the Bay of Islands. On the 18th March he finally left New Zealand, having spent a little more than two months on its shores.

After the "Astrolabe" had returned to Europe the scientific results of the voyage were published in elaborate style under the auspices of the French Government. The botanical portion was undertaken by A. Richard, one of the leading botanists of his time, and was issued in 1832, under the title of "Essai d'une Flore de la Nouvelle Zélande," accompanied by a folio atlas of plates. Richard included not only the species collected in the two expeditions of Duperrey and D'Urville, but also most of those obtained by Forster in Cook's second voyage. Altogether 380 species are enumerated, 211 of which are phaenogams and 169 cryptogams, 51 of the latter being ferns. It is the first publication dealing with the flora of New Zealand as a whole, and possesses considerable merit, so much so that it is to be regretted that so little use of it has been made by New Zealand botanists.

Early in the nineteenth century a trading intercourse sprang up between the North Island and Sydney, and by degrees a small European settlement began to form at the Bay of Islands. This led to occasional visits from colonial botanists and explorers, and much additional information was thus obtained respecting the flora. In 1825 Mr. Charles Fraser, Government Botanist and Superintendent of the Sydney Botanical Gardens, landed for a day in the Bay of Islands, and made a small collection of plants. In 1826 his successor, the indefatigable Allan Cunningham, paid a visit of over five months' duration. Through the assistance afforded by the resident missionaries he was able to explore the greater part of the Bay of Islands district, and to visit Whangaroa and Hokianga, making extensive and valuable collections. In 1833 his brother, Richard Cunningham, arrived in H.M.S. "Buffalo," which had been sent to New Zealand by the Admiralty to obtain a cargo of kauri spars for experimental purposes. He also spent nearly five months in travelling through the Bay of Islands, Whangaroa, and Hokianga districts. In 1838 Allan Cunningham paid a second visit, remaining at the Bay of Islands through the whole of the winter and early spring; but the precarious state of his health prevented all active work, and his collections were consequently small. He returned to Australia in October, 1838, utterly exhausted and worn out, as his biographer says, "by twenty-five years of unwearied exertions and laborious travel," and, after lingering a few months, died at Sydney in June, 1839.

During a short visit to England Allan Cunningham had prepared for publication a sketch of the flora of New Zealand, entitled "Florae Insularum Novae-Zealandiae Precursor; or, A Specimen of the Botany of the Islands of New Zealand." The first part of this work appeared in the "Companion to the Botanical Magazine," vol. ii; the remaining portions in the "Annals and Magazine of Natural History," vols. i to iv.

In it Cunningham enumerates the whole of the species published by Forster and A. Richard, including also some of Banks and Solander's plants which had been described by other botanists. To these he adds the new species discovered during his first visit and that of Richard Cunningham. Altogether the Precursor includes the names of 639 species, of which 394 are phaenogams and 245 cryptogams. Although containing much valuable information, it bears evident marks of hasty preparation, and can hardly be considered an adequate memorial of its enthusiastic and talented author. The herbarium of both the Cunninghams is now preserved at Kew.

Mr. J. C. Bidwill visited New Zealand for the first time in 1839, and after a short stay at the Bay of Islands proceeded to the Bay of Plenty, from whence he journeyed to Rotorua and Taupo. Crossing Lake Taupo he reached Lake Rotoaira; and, using the Native village there as a base of operations, succeeded in exploring the spurs of Tongariro and in ascending the cone of Ngauruhoe, being the first European to accomplish the feat. He returned by way of Rotorua, Tauranga, and the Thames Valley. His collections, which were forwarded to Sir W. J. Hooker, were the first made in the mountainous interior of the North Island, and contained several interesting discoveries, as *Veronica tetragona*, *Dacrydium laxifolium*, *Senecio Bidwillii*, *Dracophyllum recurvum*, &c. A few years later he visited the mountains of Nelson, forming a very interesting collection of mountain-plants, which were also forwarded to Sir W. J. Hooker.

In the years 1839–40–41 Dr. Ernest Dieffenbach made extensive travels in New Zealand as naturalist to the New Zealand Company. In addition to an examination of the whole of the northern peninsula, from the North Cape to Auckland, he travelled along the western coast to Raglan and Kawhia, and, crossing to the Waipa Valley, followed the western bank of the Waikato River to Lake Taupo. A project to ascend Tongariro and Ruapehu was frustrated by the opposition of the Maoris, and he returned to Auckland by way of Rotorua, Tauranga, and the Thames Valley. During another journey he explored a large part of the Taranaki District, and was the first European to ascend Mount Egmont. He also visited Wellington, Wanganui, and Kapiti Island, and spent some time in the exploration of Queen Charlotte Sound, Cloudy Bay, and the whaling-stations on the north-east coast of the South Island. Finally, he paid a visit to the Chatham Islands, and brought away the first plants collected in that outlying dependency of the colony. On his return to England Dieffenbach published his "Travels in New Zealand," the two volumes of which are replete with interesting matter relating to the flora, fauna, and Native inhabitants. His botanical collections were presented to the Kew Herbarium, but, according to Sir J. D. Hooker, they are "most scanty compared with the great extent of interesting ground he passed over."

In July, 1840, the French corvette "L'Aube" arrived at the Bay of Islands, and after a brief stay proceeded to Akaroa, remaining there until November, 1841. In January, 1842, "L'Aube" was replaced by "L'Allier," which was stationed at Akaroa until January, 1843. The surgeon attached to these two vessels, M. E. Raoul, made excellent collections, mainly at Akaroa, and, as he was the first botanist to investigate the flora of the eastern side of the South Island, many of his plants were altogether new. Raoul first of all published his discoveries in the "Annales des Sciences Naturelles" (Series III, vol. ii), but subsequently he prepared a work of

wider scope under the name of "Choix de Plantes de la Nouvelle Zélande," illustrated with thirty beautiful plates. In it he reprints the descriptions previously published in the Annales, and gives an enumeration of the known species of the flora, including about 950 species, of which rather more than 500 are flowering-plants. But he accepted all Cunningham's species, many of which were not well founded, and also included no small number of synonyms and introduced plants. If these are eliminated his list will be reduced to under 800. Raoul's services to New Zealand botany have been well commemorated in the genus *Raoulia*, dedicated to him by Sir J. D. Hooker.

In the year 1837 an elaborately organized expedition, consisting of the corvettes "Astrolabe" and "Zélée," under the command of Admiral D'Urville, was despatched by the French Government for the purpose of exploration in the Antarctic regions. The expedition visited the Auckland Islands during 1839, when M. Hombron, who acted as botanist, made a collection of plants, the first formed in the locality. The official record of the voyage, which appeared under the title of "Voyage au Pôle Sud et dans l'Océanie," contains a folio atlas of botanical plates prepared under the direction of M. Hombron, and two volumes of descriptive matter; one including the Cryptogamia, by Montaigne, the other the phaenogams, by Decaisne. Drawings and descriptions were given of several species from the Auckland Islands; but all, or nearly all, had been already described in Hooker's "Flora Antarctica," presently to be alluded to.

About the same period the well-known American Exploring Expedition, under the command of Captain Wilkes, visited both the Bay of Islands and the Auckland Islands. Several naturalists were attached to the expedition, and collections of considerable importance were formed. After Wilkes's return, and after many delays, the botanical collections were entrusted to the eminent American botanist, Asa Gray. An account of the phaenogams ultimately appeared (in 1854) in two volumes quarto, with a folio atlas of 100 plates. The number of New Zealand plants enumerated is not large, but Asa Gray's critical and descriptive remarks are in many cases of considerable value.

We now arrive at the Antarctic Expedition of Sir James Clark Ross, which left England in September, 1839, for the purpose of investigating the phenomena of terrestrial magnetism in high southern latitudes, and of prosecuting geographical discovery in the Antarctic regions. It consisted of two vessels, the "Erebus," commanded by Ross, and the "Terror," under Captain Crozier. To the first-mentioned vessel Dr. (now Sir J. D.) Hooker was attached as assistant surgeon and naturalist, whilst Dr. Lyall served in a similar capacity on the "Terror." After calling at the Cape of Good Hope, Kerguelen Island, and Tasmania, the expedition arrived at the Auckland Islands on the 20th November, 1840, remaining until the 12th December. On the 13th December it reached Campbell Island, leaving again on the 17th for a cruise to the Antarctic Circle and the south polar regions. Although the Auckland Islands had been visited by D'Urville and Wilkes the previous year, nothing had been published respecting the vegetation, and with characteristic ardour Hooker devoted himself to its exploration. The luxuriance of the flora and the relatively large proportion of plants with brilliant and conspicuous flowers at once attracted attention. Hooker goes so far as to say, when writing of *Bulbinella Rossii*, "Perhaps no group of islands on the surface of the globe, of the same limited extent and so perfectly isolated, can boast of

three such beautiful plants, peculiar to their flora, as the *Pleurophyllum speciosum*, *Celmisia vernicosa*, and the subject of the foregoing description." Under such circumstances the scrutiny given to the vegetation was keen and almost exhaustive, as evidenced by the fact that but few additions have been made by later explorers. The first volume of the "Flora Antarctica," prepared by Hooker after his return to England, and issued in 1844, is confined to the flora of the Auckland and Campbell Islands. It contains descriptions of 100 species of flowering-plants and twenty ferns and fern-allies, together with numerous mosses, *Hepaticae*, and other cryptogams, and is illustrated with eighty beautifully prepared plates, fifty-six of which are of phaenogams. Altogether, it is a splendid monument of painstaking exploration and research, and it seems almost incredible that the observations and material on which it is founded should have been collected in less than a month.

After the discovery of Victoria Land in the summer of 1840–41 Sir James Ross returned to Tasmania, proceeding from thence to the Bay of Islands, which was reached on the 14th August, 1841. Here the expedition remained until the 23rd November. During this period Sir J. D. Hooker was actively engaged in collecting materials for his projected "Flora of New Zealand," receiving much assistance from Mr. Colenso and other residents. He remarks that his collections "contained no novelty amongst flowering-plants not known to Mr. Colenso and Dr. Sinclair, with whom I spent many happy days. Amongst cryptogamic plants I collected much that was then new, but most of the species have since been found elsewhere."

With the departure of the Antarctic Expedition in 1841 the first period of botanical discovery in New Zealand—that of investigation by visitors from abroad—may be said to have closed; for, although several scientific expeditions, such as the "Novara," "Challenger," &c., have since visited the colony, they have done little in the way of botanical research. Since 1841 the advance which has been made is almost wholly due to the efforts of the colonists themselves.

The foremost place among resident botanists and explorers must be granted to the Rev. W. Colenso, both on account of the number and variety of his discoveries, and the ardour with which, for a period of no less than sixty-five years, he continued to observe and to collect facts and specimens in almost all branches of natural science, always giving the leading place to botany. Arriving in New Zealand in 1834 he was induced, first by the visit of the illustrious Darwin in the "Beagle" in 1835, and later by Allan Cunningham in 1838, to take up the study of the botany of his adopted country, forwarding his specimens from time to time to Sir W. J. Hooker at Kew. At first his collections were confined to the district between Whangarei and the North Cape, but he soon enlarged his field of operations. Space will not permit of a full account of his many journeys, which practically covered the whole length of the North Island, but the following were the most important. In 1841–42 he travelled on foot from Hicks Bay to Poverty Bay, and from thence inland through the rugged and almost inaccessible Urewera country to Lake Waikaremoana, which he was the first European traveller to reach. He then crossed the Te Whaiti Mountains to Ruatahuna, from whence he proceeded to Rotorua and Tauranga. Striking inland again, he followed the upper Thames Valley to its head, and, crossing to the Waikato River, canoed a hundred miles down the river to its mouth.

From thence he followed the west coast to the Kaipara Harbour, then again made for the east coast at Mangawai, finally reaching the Bay of Islands by way of Whangarei and Whangaruru. In 1843 he journeyed from Hicks Bay to Poverty Bay, and thence by sea to Castle Point. From that locality he proceeded to Ahuriri (Hawke's Bay) and the Wairoa River, which he ascended to Waikaremoana, returning by way of Rotorua and Tauranga. In 1844 he transferred his residence from the Bay of Islands to Hawke's Bay, and in the following year made his first expedition to the summit of the Ruahine Range, finding there a harvest of previously unknown alpine and subalpine plants. In 1847 he travelled by way of Titiokura and the Mohaka River to Taupo and inland Patea, passing along the flanks of Tongariro and Ruapehu, and returning to Hawke's Bay over the Ruahine Range, which he was the first European to cross. These journeys and many others, all made on foot, with a few Native companions only, and often under circumstances of great privation and no little danger, are evidence of the ardour and enthusiasm with which Mr. Colenso carried on his botanical explorations in the early days of the colony. Nor did his zeal diminish with age, for the "Transactions of the New Zealand Institute" contain papers written by him describing plants collected during a journey made to the flanks of the Ruahine Range in his eighty-fifth year. In addition to numerous writings on the Maori race, on which he was for many years the chief authority, Mr. Colenso contributed no less than fifty-nine papers on botanical subjects to the "Transactions of the New Zealand Institute." Very few volumes, from the foundation of the Institute to the time of his death, are without a communication from his pen. It is true that in his later descriptive writings he adopted views as to the circumscription of species which are in conflict with those held by all other New Zealand botanists, and thus introduced a vast number of synonyms into the flora; but that is a circumstance which must not detract from the recognition of his undoubted services to the botany of New Zealand.

Dr. Andrew Sinclair was originally a surgeon in the Royal Navy, and first became known as a botanist from the collections he made while attached to the surveying expedition of H.M.S. "Sulphur" to the Pacific coasts of North and South America. He first visited New Zealand in 1841, during the stay of the Antarctic Expedition at the Bay of Islands, and accompanied Sir J. D. Hooker and Mr. Colenso in numerous botanical expeditions. Returning to Australia, he met with Captain Fitzroy, who was then on his way to New Zealand as Governor, and who engaged him as private secretary. Not long after his arrival in the colony he was appointed to the post of Colonial Secretary, which he retained for several years. His leisure time was almost entirely devoted to botanical pursuits, and he collected largely in most parts of the North Island, transmitting copious suites of specimens to Kew, where they constituted a large part of the material used by Hooker in the elaboration of the "Flora Novae-Zealandiae." After the establishment of parliamentary government in New Zealand Dr. Sinclair vacated his position, and after a brief sojourn in England returned to New Zealand, with the intention of devoting himself to botanical work. After a short stay in Auckland he proceeded to Nelson, where he made important collections, adding many species to the alpine flora. He then repaired to Canterbury, and joined the late Sir Julius Haast in the geological and botanical survey then being made of the Southern Alps. There, in the year 1861, he was unfortunately drowned in an

imprudent attempt to ford the Rangitata River. Although he never published anything of importance on New Zealand plants, his name will always be remembered as one of the pioneers of botanical discovery in the colony.

In the years 1847–51, H.M.S. "Acheron," under the command of Captain Stokes, was engaged in the survey of the coast-line of New Zealand, and especially of the western and south-western portions. Captain Stokes was accompanied as surgeon-naturalist by Dr. Lyall, who had served in a similar capacity in H.M.S. "Terror" in the Antarctic Expedition, and who made large collections, especially of Cryptogamia. Milford Sound, Chalky Inlet, Dusky Bay, Preservation Inlet, and both shores of Foveaux Strait were the chief localities botanized in by Lyall during this expedition. Among the plants collected were the first specimens of the magnificent *Ranunculus Lyallii*.

In 1853 there appeared the first volume, containing the flowering-plants, of Sir J. D. Hooker's "Flora Novae-Zealandiae"; the second volume, including the cryptogams, following in 1855. The publication of this important work, in every way worthy of the reputation of its distinguished author, marked a new era in the history of the botany of New Zealand. For the first time the student was provided with an account of the flora characterized by aptness of description and accuracy of detail, and prepared by a botanist who had not only studied and collected a large proportion of the species in their native habitats, but whose position gave him ample opportunities of examining the material upon which the publications of his predecessors were founded. Under such advantages the synonyms and false species incorrectly included by previous writers disappeared, and the flora assumed more of its real proportions and extent. Altogether, the Flora contains descriptions of 1,767 species, or more than double the number given in the last previous enumeration, that of Raoul in the "Choix de Plantes." Of the total number, 731 are flowering-plants and 119 ferns or fern-allies, the remainder falling into other orders of Cryptogamia. The value of the work is much enhanced by the 130 carefully prepared plates which accompany it, and by the philosophic Introductory Essay dealing with the affinities and distribution of the species.

The eleven years subsequent to the publication of the Flora formed a period of great activity in botanical research in the colony. This was mainly due to the rapid settlement of the South Island, which led to the exploration of the central range of mountains, from Nelson to Otago, and the consequent discovery of the rich alpine flora existing thereon. The earliest worker in this field was Sir D. Monro, the first of whose contributions was received at Kew while the Flora was in progress. He explored a large part of north-eastern Nelson and Marlborough, making many capital discoveries, such as the magnificent *Olearia insignis*, *Helichrysum coralloides*, *Celmisia Monroi*, *Senecio Monroi*, &c. His sole publication, so far as I can learn, is an interesting essay on the "Geographical Botany of Nelson and Marlborough," printed in the first volume of the "Transactions of the New Zealand Institute."

Mr. W. T. L. Travers arrived in Nelson in 1849. About 1854 he took up the study of the alpine flora of the South Island, making many excursions into remote and little-explored districts, and forming copious collections, the whole of which were forwarded to Kew. Among the localities botanized over by him were the upper Buller Valley, including

Lakes Rotoiti and Rotoroa; the whole of the Wairau Valley, from the mouth of the river to its sources in the rugged Spenser Mountains; the upper Clarence Valley, with its tributaries; the Waiau and Hurunui Valleys, with the adjacent mountains; also the Canterbury Plains and various parts of Banks Peninsula. His discoveries included many singular and prominent species, and the genus *Traversia* was named in his honour by Sir J. D. Hooker. He contributed many papers and addresses more or less relating to the botany of the colony to the "Transactions of the New Zealand Institute," and was an earnest and assiduous supporter of botanical research up to the time of his death in 1903.

The well-known geologist and explorer Sir Julius Haast first landed at Auckland in 1858. Meeting Dr. Hochstetter, the geologist to the "Novara" expedition, he travelled with him through the greater part of the interior of the North Island, subsequently visiting portions of the Nelson District. After Hochstetter's departure, he accepted an engagement from the Nelson Provincial Government to explore the western and southern portions of the province, a work which occupied the greater portion of 1860, and during which he became familiar with the alpine vegetation of that part of the colony. In the following year he was appointed geologist for the Province of Canterbury, and at once commenced a series of expeditions into the then little-known Southern Alps for the purpose of studying their geology and physical structure, and of forming botanical and zoological collections. The botanical results, with which we are alone concerned, proved to be most important, and cast a flood of light on the nature and distribution of the alpine flora of the colony. I quite concur with Sir J. D. Hooker's opinion that it is difficult to imagine how Sir Julius Haast, with so many and such arduous duties as surveyor and geologist, could have personally effected so much for botany as he has done. Most of his botanical work was performed in the years between 1860 and 1870, but his interest in the subject remained undiminished until his death in 1887. His name is appropriately commemorated in the genus *Haastia*, the three or four species of which rank amongst the most curious and remarkable in the flora. His collections were either forwarded to Kew or distributed among European museums, but few being retained in the colony.

Dr. Lauder Lindsay, a well-known British botanist, visited New Zealand in the summer of 1861–62, and spent nearly four months in investigating the botany of eastern Otago, the district examined stretching from Dunedin to the mouth of the Clutha River, and inland to Tuapeka. The results of his journey were published in 1868 under the title of "Contributions to New Zealand Botany," with four coloured plates. Dr. Lindsay gives the total number of species collected at 612, of which 199 were phaenogams and 413 cryptogams. The memoir contains much information of value, the critical notes in particular being copious and interesting.

Mr. John Buchanan arrived in New Zealand prior to 1860, taking up his residence in Dunedin. He at once commenced an assiduous study of the native vegetation, making many important discoveries and collecting large suites of specimens. In 1862 he accepted the appointment of draughtsman and botanist to the Geological Survey of Otago, then being organized by Dr. (now Sir James) Hector. In the two or three years immediately following he accompanied Sir James Hector in a succession of adventurous journeys, during which a great part of central and western Otago was visited and explored. The collections made, which were mostly forwarded to Kew, contained many interesting and remarkable discoveries, among

which may be mentioned *Ranunculus Buchanani*, *Pachycladon novae-zea landiae*, *Hectorella caespitosa*, *Azorella exigua*, *Celmisia ramulosa*, *Veronica Buchanani*, &c. In 1865 Mr. Buchanan prepared his "Sketch of the Botany of Otago," the first local Flora issued in the colony, and a work of considerable merit, evidencing much industrious research. It was written at the request of the Commissioners of the New Zealand Exhibition of 1865, but was not actually published until 1869, when it appeared in the first volume of the "Transactions of the New Zealand Institute." On the establishment of the Geological Survey of New Zealand in 1866 he was appointed draughtsman and botanist, and removed to Wellington. He was successively engaged in botanical explorations of the North Auckland Peninsula, the Kaikoura Mountains, and Mount Egmont, some interesting notes on the two last-mentioned districts being printed in vol. x of the "Journal of the Linnean Society." In 1873 he published a valuable paper on the flora of the Wellington Provincial District; followed in 1874 by his "Flowering-plants and Ferns of the Chatham Islands," based on the collections made by Mr. H. H. Travers in 1863 and 1871. His most important work, published in 1880, is the "Indigenous Grasses of New Zealand," a folio volume of nearly two hundred pages, illustrated with sixty-four lithographic plates. It contains descriptions of the whole of the species then known to inhabit New Zealand, together with notes on their economic value, distribution, &c. Mr. Buchanan's contributions to New Zealand botany include forty separate papers, stretching through twenty volumes of the "Transactions of the New Zealand Institute." His last communication appeared in 1887, after which persistent ill health compelled him to give up botanical work. His death took place in 1898. His earlier collections were mostly forwarded to Kew, but in later years he formed an extensive herbarium for the Colonial Museum. His private collections, drawings and analyses, manuscript notes, &c., were bequeathed to the Otago University Museum.

No account of the history of botanical discovery in New Zealand would be complete without reference to the labours of Sir James Hector, the first Director of the Geological Survey and Manager of the New Zealand Institute. Arriving in the colony in 1861, his first duty was a geological and topographical exploration of the Province of Otago, a work which at that time involved many difficulties and hardships, and no small amount of danger. As previously mentioned, he obtained the services of Mr. Buchanan as collector and artist; but his own share in the work of botanical exploration was by no means small. That he fully grasped the leading features of plant-distribution in the South Island is evidenced by his essay "On the Geographical Botany of New Zealand," printed in the first volume of the "Transactions of the New Zealand Institute." After his removal to Wellington in 1866 the official duties appertaining to the Geological Survey and Colonial Museum, &c., left little time for botanical research; but he has never missed an opportunity of promoting the efforts of others. In fact, it can be said that from the time of his arrival in the colony up to the present day no attempt has been made to investigate its flora which has not had his countenance and support. His services to botanical science are fitly commemorated in the remarkable endemic genus *Hectorella*, and in the magnificent *Senecio Hectori*, one of the finest of the arborescent *Compositae* of the colony.

In 1863 Mr. H. H. Travers visited the Chatham Islands for the purpose of investigating its flora, at that time only known from a few plants collected

by Dr. E. Dieffenbach in 1840. He remained in the group for several months, and succeeded in forming large collections. On his return these were placed in the hands of the late Baron Mueller, of Melbourne, who published the results in his "Vegetation of the Chatham Islands," issued in 1864. In it Baron Mueller enumerates 129 species, of which sixty-two are phaenogams and sixty-seven cryptogams. Seven new species were described. The work forms an important addition to the botanical literature of the colony, but New Zealand botanists entirely repudiate the peculiar views entertained by the author respecting the circumscription of many of the species. For instance, he merges the whole of the species of *Veronica* found in the Chathams, together with thirteen others from New Zealand, into one collective species, to which he gives the new name of *V. Forsteri*. An excellent account of Mr. Travers's visit was contributed by himself to the first volume of the "Transactions of the New Zealand Institute." In 1871 he again visited the group, adding largely to his previous list. On this occasion his collections were worked out by Mr. Buchanan in his paper on "The Flowering-plants and Ferns of the Chatham Islands." Mr. H. H. Travers has also made collections on the Tararua Mountains, the Nelson mountains, and in other localities.

The important discoveries made in the interior of the South Island during the ten years following the publication of the "Flora Novae-Zealandiae," and the increasing demand for a concise and inexpensive account of the plants of the colony, induced the New Zealand Government to make arrangements with Sir J. D. Hooker for the publication of such a work. The first part, containing the flowering-plants and ferns, appeared in 1864, under the title of "Handbook of the New Zealand Flora"; the concluding part, comprising the mosses, *Hepaticae*, and lower cryptogams, followed in 1867. Its publication at once showed the great advance which had been made in elucidating the flora. The 731 species of flowering-plants and 119 ferns known in 1853 were increased to 935 and 135 respectively, an increase of nearly one-quarter; while the additional information obtained with regard to the distribution of the species was correspondingly large. The general plan of the work was in accordance with that recommended by Sir W. J. Hooker for a uniform series of floras of the British colonies, a project which has been to a considerable extent carried out. In point of execution the Handbook realized all the expectations which could have been entertained. The clearness and excellence of the descriptions and their general accuracy are most noteworthy, especially when it is considered that a large proportion of the species have been examined and described by the author alone. Its publication gave an immense impetus to the study of the indigenous vegetation, and it must always remain the foundation for future systematic work on the botany of the colony.

The number of persons who have collected plants or published memoirs relating to New Zealand botany during the forty years which have elapsed since the publication of the Handbook is so large that I can only allude to the chief workers here. The first place must be accorded to Mr. T. Kirk, both from the number of his discoveries and the importance of his publications. Arriving in the colony in 1863 he at once devoted himself to its botany, his first discoveries being briefly mentioned in the appendix to the second part of the Handbook. For ten years after his arrival he resided in Auckland, his chief explorations during that period being that of the Great Barrier Island in 1867, of the north-eastern coast of the northern

peninsula in 1868, of the Thames goldfields in 1869, of the Waikato district in 1870, and of the Rotorua and Taupo districts in 1872. Among the numerous species added to the flora by these journeys are the following: *Pittosporum Kirkii*, *Pseudopanax discolor*, *Coprosma arborea*, *Olearia Allomii*, *Dacrydium Kirkii*, *Phyllocladus glauca*, and *Isoetes Kirkii*. In 1874 Mr. Kirk removed to Wellington, occupying firstly the position of Lecturer on Natural Science at Wellington College, and at a later date that of Chief Conservator of State Forests. In the performance of the duties of the latter office he travelled through the greater part of both the North and South Islands, and these journeys were always employed to the furtherance of botanical science. After his retirement from the State Forests Department he made a lengthened exploration of Stewart Island, detecting several novelties, among them the superb *Olearia Traillii*. In 1890 he paid a visit to the Auckland and Campbell Islands, adding several species to their flora. During the same voyage he landed on The Snares and Antipodes Islands, the vegetation of which was previously quite unknown. The results of this expedition were embodied in a memoir printed in the Report of the Australasian Association for 1891. Mr. Kirk was a voluminous writer, and his contributions to New Zealand botany, mostly printed in the "Transactions of the New Zealand Institute," number nearly a hundred and fifty. His most important completed work is "The Forest Flora of New Zealand," issued in 1889. Its primary object was to diffuse a knowledge of the forest resources of the colony and to describe the chief methods of timber working and conversion. It contains much information on the economic value and uses of the New Zealand timbers, together with descriptions of the species, and is illustrated with 150 plates. In 1894 he was commissioned by the New Zealand Government to prepare a Flora of the colony, a work for which he had long been collecting material, and for which his wide personal knowledge of the vegetation of the country gave him exceptional qualifications. He entered upon the work with characteristic energy and ardour; but, unfortunately, his health gradually failed, and after several serious illnesses he died in March, 1897. That portion of his work which was in a sufficiently complete state at the time of his death, comprising the *Polypetalae*, and the *Monopetalae* as far as the *Compositae*, was issued from the Government Printing Press in 1899. Although printed without the advantage of the author's supervision, and without the introductory and supplementary matter usually given in such publications, it shows very clearly the loss which botanical science has suffered through his decease, and all students will regret that he did not live to complete the work for which he had made so many preparations.

I do not propose to say anything in regard to my own researches into the flora, beyond stating that they have extended continuously from the year 1870 to the present time, and include an examination of almost the whole colony, from the Kermadec Islands and the North Cape to Otago. A list of my papers on botanical subjects will be found in Mr. Hamilton's Bibliography, printed in vol. xxxvi of the "Transactions of the New Zealand Institute" (pp. 342–72).

In the years 1874 and 1875 Dr. Sven Berggren, of the University of Lund, Sweden, made an extended visit to New Zealand, travelling through the greater portion of both Islands, and making large collections, especially of cryptogams. The new species of flowering-plants were described and beautifully illustrated in a memoir published in 1877 in the "Proceedings of the University of Lund." The *Algae* have been worked out by Dr. Nordstedt

and the late Professor J. G. Aghard, while scattered memoirs relating to other orders of cryptogams have been published from time to time by Dr. Berggren himself.

From 1875 to the present time many important contributions to our knowledge of the flora of the colony have been made by Mr. D. Petrie, formerly Chief Inspector of Schools for Otago, and now holding a similar position in Auckland. During a residence of more than twenty years in Otago he sedulously investigated the vegetation of the eastern, central, and southern portions of the province, ascending many of the mountains, and forming large collections, especially of the rarer alpine and subalpine plants. Among the species added by him to the flora are *Ranunculus Berggreni*, *Carmichaelia compacta* and *C. Petriei*, *Coprosma virescens* and *C. Petriei*, *Olearia fragrantissima*, *Celmisia prorepens* and *C. Petriei*, *Myosotis Goyeni*, *Tetrachondra Hamiltoni*, *Veronica Petriei*, *Ourisia prorepens*, &c. In company with Mr. G. M. Thomson, he also visited Stewart Island, making several discoveries of interest, as *Actinotus bellidioides*, *Liparophyllum Gunnii*, *Carex longiculmis*, and *Ehrharta Thomsoni*. In 1895 Mr. Petrie published his "List of Flowering-plants indigenous to Otago," in which he catalogues the whole of the species, numbering over 760, observed by himself in Otago, giving at the same time particulars respecting the geographical and altitudinal range of the species. Altogether forty-four papers on botanical subjects are credited to Mr. Petrie in Mr. Hamilton's bibliography of New Zealand botanical literature.

Mr. G. M. Thomson, of Dunedin, has also done excellent service towards the elucidation of the botany of Otago. As already mentioned, he accompanied Mr. Petrie in an exploration of Stewart Island, and has collected largely in the vicinity of Dunedin. Several papers on Otago plants have been contributed by him to the "Transactions of the New Zealand Institute"; but probably the most interesting of his publications are two memoirs "On the Means of Fertilization among some New Zealand Orchids" (Trans. N.Z. Inst., xi, 418) and "On the Fertilization of New Zealand Plants" (*Ibid.*, xiii, 241). His work on the "Ferns and Fern-allies of New Zealand," issued in 1882, is an accurate and useful compendium, containing descriptions of all the known species. He is also the author of an "Introductory Class-book of Botany," which has been largely used in New Zealand schools.

Mr. J. F. Armstrong, for many years resident in Christchurch, has collected largely in the Province of Canterbury, and has published several papers of value. Among them are his "Sketch of the Flora of the Province of Canterbury" (Trans. N.Z. Inst., xii, 325) and "Synopsis of the New Zealand Species of Veronica" (*Ibid.*, xiii, 344), the latter publication containing descriptions of several new species. He also founded the genus *Corallospartium* for the reception of the remarkable plant first described by Sir J. D. Hooker under the name of *Carmichaelia crassicaulis*.

The Right Rev. W. L. Williams, Bishop of Waiapu, has for thirty years given special attention to the botany of the East Cape and Hawke's Bay districts, carefully noting the chief features of the vegetation, and collecting copiously. Among his discoveries may be mentioned the remarkable *Carmichaelia Williamsii*, one of the most local plants in the colony. Mr. Kirk's paper on the "Botany of the East Cape District" (Trans. N.Z. Inst., xxix, 509) is largely founded on Bishop Williams's specimens and notes. The collection of Maori plant-names is also a subject to which he has devoted much time and labour, and the list appended to this work is in great measure due to his friendly co-operation.

Mr. A. Hamilton, the present Director of the Colonial Museum, made an interesting collection of plants at Okarito in 1878, which included several novelties. Among them was the remarkable species described by Hooker as *Euphrasia disperma*, which has since been taken by Wettstein as the type of his genus *Anagosperma*. At a later date he botanized in the Hawke's Bay District, along the flanks of the Ruahine Range, and elsewhere on the eastern side of the North Island. In 1894 he visited Macquarie Island, and, although much hindered by exceptionally severe weather and other untoward circumstances, succeeded in adding considerably to our knowledge of the botany of the island. A list of the plants collected will be found in his "Notes on a Visit to Macquarie Island" (Trans. N.Z. Inst., xxvii, 559).

Mr. H. Hill, of Napier, has also collected largely in the Hawke's Bay and East Cape districts. Many of his specimens were communicated to Mr. Colenso, and were described by that gentleman as new species. He was the first to find the widely distributed *Peperomia reflexa* in the colony, and to rediscover the plant to which the name of *Veronica Colensoi* was originally applied by Hooker.

Mr. J. D. Enys, for several years resident at Castle Hill, in the middle portion of the Waimakariri basin, and a keen observer in many branches of natural science, made large collections in the Canterbury Alps in the years between 1874 and 1890. Among his discoveries may be mentioned *Ranunculus Enysii* and *R. paucifolius*, *Carmichaelia Enysii*, *Ligusticum Enysii*, *Botrychium lunaria*, &c. He also paid a visit to the Chatham Islands, bringing back a few interesting plants, among which were the first specimens of the endemic *Sonchus grandifolius*. His collections were for the most part communicated either to Mr. Kirk or myself.

Mr. James Adams, of Thames, has botanized in several parts of both the North and South Islands, making several interesting discoveries, the chief of which are *Celmisia Adamsii*, *Loranthus Adamsii*, and *Myosotis amabilis*. His papers on the "Botany of Te Aroha Mountain" (Trans. N.Z. Inst., xvii, 275), on the "Botany of Te Moehau" (*Ibid.*, xxi, 32), and the "Botany of Hikurangi Mountain" (*Ibid.*, xxx, 414) contain much interesting matter bearing on the distribution of the New Zealand flora.

Mr. F. R. Chapman (now Mr. Justice Chapman) has collected in Otago, and in 1890 visited the Auckland Islands and other islands to the south of New Zealand. His paper on "The Outlying Islands South of New Zealand" contains much valuable information of a botanical nature. He has also published two papers containing descriptions of certain new species of *Celmisia* (Trans. N.Z. Inst., xxii, 444; and xxiii, 407).

Professor J. H. Scott, of Dunedin, visited Macquarie Island in 1880. On his return he published an excellent account of the fauna and flora (Trans. N.Z. Inst., xv, 484), including a catalogue of the plants observed by him.

Among others who have interested themselves with New Zealand botany between the publication of the Handbook and the year 1895 may be mentioned the late Mr. Justice Gillies, Captain Hutton, T. H. Potts, C. Traill, S. Percy Smith, J. Rutland, P. Goyen, Captain G. Mair, A. T. Urquhart, H. Tryon, Archdeacon Walsh, T. W. Kirk, J. W. Hall, J. Tennant, and J. Baber.

In 1896 Dr. L. Diels, of Berlin, published in Engler's "Botanical Year-book" a paper entitled "Vegetations-biologie von Neu-Seeland," which deserves special mention on account of being the first attempt to

prepare an account of the flora of the colony from an oecological standpoint. Although based entirely on herbarium material and on the observations of other botanists and collectors, and consequently containing errors both of omission and commission, it is nevertheless a work of considerable originality and merit, and is well worth the attention of all students of the flora.

Since 1897 by far the most important contributions to our knowledge of the New Zealand flora have been made by Dr. L. Cockayne, and I regret that only brief mention can be made of his work here. In three papers "On the Seedling Forms of New Zealand Phanerogams and their Development" (Trans. N.Z. Inst., xxxi, 354; xxxii, 83; and xxxiii, 265) he describes with considerable detail the seedling leaves of many New Zealand plants, giving numerous figures, and in several instances tracing the gradual development of the foliage into the mature stage. Much information is given respecting the life-history of the species treated of, particularly in the genera *Carmichaelia* and *Veronica*. In the latter genus most of the species with scale-like leaves are very fully discussed, and their early foliage described. In a paper on the "Plant-geography of the Waimakariri River Basin" (Trans. N.Z. Inst, xxxii, 95) Dr. Cockayne makes the first attempt in the colony to treat the flora of a district from an oecological point of view. It was followed by his "Account of the Plant-covering of Chatham Island" (Trans. N.Z. Inst., xxxiv, 243), a publication which has thrown a flood of light on the nature and composition of the flora of this seldom-visited appanage of New Zealand. Lastly, the volume of Transactions for 1904 contains an elaborate paper on "An Excursion to the Southern Islands of New Zealand," in which he not only gives a detailed account of the "plant-formations" which make up the flora of the islands visited, but also contributes a list of the flowering-plants and ferns, and a sketch of the physiography, geology, climate, &c. These papers, which mark an entirely new epoch in the history of botanical investigation in New Zealand, will induce all students of the flora to look forward with impatience for the appearance of the general work on the plant-geography of New Zealand which it is understood that Dr. Cockayne has in preparation.

The very important researches made by Professor A. P. W. Thomas into the life-history of *Phylloglossum*, summarized in his "Preliminary Account of the Prothallium of *Phylloglossum*" (Proc. Roy. Soc., vol. lxix, pp. 285–91) deserve special mention; as also his suggestive paper on "The Affinity of *Tmesipteris* with the *Sphenophyllales*" (*Ibid.*, p. 343–50). The more detailed information promised with respect to both these communications will be eagerly looked forward to by New Zealand botanists.

During the last five years Mr. W. Townson, of Westport, has diligently explored the greater portion of south-western Nelson, from the Mokihinui River southwards to the Grey River, repeatedly ascending all the higher peaks of the coast ranges, as Mount Frederic, Mount Rochfort, Mount William, Mount Faraday, Mount Buckland, &c. He has also visited the Lyell Mountains, and many of the high peaks flanking the Buller Valley, as far up the river as Mount Murchison and Mount Owen. Most of this large district had never been carefully examined for plants, and Mr. Townson has consequently reaped a rich harvest of novelties, most of which are described in this work. Among them are *Aciphylla Townsoni*, *Celmisia dubia*, *Dracophyllum Townsoni* and *D. pubescens*, *Gentiana Townsoni*, *Veronica divergens* and *V. coarctata*, and the interesting new genus of

Orchideae which I have named in his honour *Townsonia*. Mr. Townson's specimens, which have been collected with great care and judgment, have been mainly forwarded to me for the purposes of this work, and have proved of much service in determining many questions relating to the geographical range of the species.

Mr. H. J. Matthews, the present head of the Forestry Department, has collected in many parts of the colony, adding largely to our knowledge of the range of the species, and obtaining a few novelties, notably the beautiful *Ranunculus Matthewsii*, described in the appendix to this work. He has also done excellent service in forming an extensive collection of living plants in his garden at Dunedin, especially of the rarer alpine and subalpine species. If this collection is maintained and extended it will prove invaluable for affording the means of leisurely study and comparison in difficult genera like *Veronica* and *Celmisia*, &c.

Mr. F. G. Gibbs, of Nelson, has done excellent work during the last ten years in the Nelson District, both on the Dun Mountain Range and on the chain of mountains extending northwards from Mount Arthur to Collingwood. Among his special discoveries are the curious *Veronica Gibbsii*, *Gentiana vernicosa*, *Celmisia Gibbsii*, &c.

The Marlborough District has been carefully and closely examined by Mr. J. H. Macmahon, who has made several finds of importance, especially in the neighbourhood of Mount Stokes. *Celmisia Macmahoni*, *C. Rutlandii*, and *Veronica rigidula* are interesting novelties first observed by him.

Mr. R. H. Matthews, of Kaitaia, has assiduously collected in most parts of Mongonui County, paying special attention to the *Orchideae*. He has added *Corysanthes Matthewsii* and *Chiloglottis formicifera* to the flora, and has succeeded in refinding *Pittosporum obcordatum*, which for sixty years after its original discovery by Raoul had eluded the search of New Zealand botanists.

Mr. H. Carse, now resident in Mongonui County, has botanized in several portions of the Auckland Provincial District. He has given special attention to the *Cyperaceae*, adding *Schoenus Carsei* and *Lepidosperma filiforme* to the list of those already known to occur in the colony. He was also the first to observe the curious little plant which I have provisionally described under the name of *Trithuria inconspicua*.

For several years Mr. F. A. D. Cox has carefully investigated the flora of the Chatham Islands, obtaining much new information relating to the distribution and environment of the species, and collecting a few novelties. His specimens, often accompanied by valuable notes, have been forwarded to Mr. Kirk, Dr. Cockayne, and myself.

Other recent workers are R. Helms, R. J. Kingsley, J. Dall, D. W. Bryant, Elsdon Best, E. W. Andrews, J. B. Simpson, H. Nairn, J. Annabell, J. B. Lee, and T. P. Arnold.

In the preceding sketch I have made no attempt to include the names of those authors who have published general works or special monographs in which New Zealand plants are casually mentioned or described. Nor have I mentioned the labours of those who have attended solely to the lower cryptogams, a branch of the flora which is outside the scope of the present work.

HISTORY OF BOTANICAL DISCOVERY IN NEW ZEALAND FROM 1905 TO 1924.

(By W. R. B. Oliver.)

Many investigators have contributed to the literature dealing with the flora of New Zealand since the publication of the first edition of the Manual. Progress has been made mainly along three lines: firstly, systematic botany, including the description of new species and the recording of the distribution of native plants; secondly, ecological botany, or the description of vegetation and the relations between plants and their environment; and, thirdly, plant anatomy, or the description of the minute structure of New Zealand plants. In addition to these several papers have been published on the origin of species in New Zealand, the chemical characteristics of the native flora, and on naturalized plants. The work of the past twenty years may conveniently be reviewed under these headings.

SYSTEMATIC BOTANY.

In his account of the botanical discovery published in the first edition of this Manual Mr. Cheeseman modestly passes over his own work with the remark that it had then extended over a period of about thirty-five years and included an examination of almost the whole of the Dominion.

Mr. Cheeseman's writings at the time of his death extended over a period of fifty-one years, during which time about one hundred contributions, mainly to botanical subjects, were published under his name. Under the circumstances in which the present edition of the Manual is issued I have thought it would be fitting to publish a complete list of his works, so have appended a classified bibliography following this account.

While Mr. Cheeseman was preparing the first edition of his work he suspended publication of smaller papers. In 1907 he began a series of articles, entitled "Contributions to a Fuller Knowledge of the Flora of New Zealand," and mainly supplementing the information given in the Manual. Simultaneously he published a number of smaller papers containing descriptions of new species. His main contribution, however, after the appearance of the first edition of the Manual was the quarto work in two volumes, "Illustrations of the New Zealand Flora," containing 250 plates with letterpress. The latter was written by Mr. Cheeseman. The plates were drawn by Miss Matilda Smith of the Kew Herbarium, while Mr. W. B. Hemsley supervised such portion of the work as was done in England. Two other important contributions from Mr. Cheeseman that have appeared within the last twenty years are the botany of the islands to the south of New Zealand, published in the "Subantarctic Islands of New Zealand," issued by the Philosophical Institute of Canterbury in 1909, and an account of the flora of Macquarie Island, published in the "Reports of the Australasian Antarctic Expedition" in 1919.

Altogether Mr. Cheeseman's works on New Zealand systematic botany, as may be judged from the list appended, occupy one of the foremost positions in the literature of New Zealand plants, while the present edition of the Manual will long remain the standard work on the flora.

Dr. D. Petrie has continued to publish regularly in the "Transactions of the New Zealand Institute" descriptions of new species and other information relating to native plants. He contributed the article on the Gramineae to the volume on the "Subantarctic Islands of New Zealand," and published an account of the plants of Mount Hector, and notes on the pollination of the puriri, and *Rhabdothamnus Solandri*.

Besides the ecological work mentioned in the next section, Dr. L. Cockayne has published a number of papers (Trans. N.Z. Inst.) recording the distribution of plants, describing new species, and offering critical remarks on others.

Mr. B. C. Aston has explored several of the mountain-ranges of New Zealand, and has published general accounts of the vegetation with lists of species of the Tararua and Ruahine Ranges and of Mount Tarawera. He has also published a useful list of the plants of the Wellington Province.

Mr. R. M. Laing has explored several portions of the Canterbury Province, and has published (Trans. N.Z. Inst.) accounts of the plants of the Spenser Mountains and Banks Peninsula. Together with Miss E. W. Blackwell, he published in 1906 a volume on the plants of New Zealand, describing and illustrating the more important species.

Mr. D. L. Poppelwell has visited many localities in Otago District and Stewart Island, and has contributed to the "Transactions of the New Zealand Institute" several papers dealing with different localities, including the Eyre Mountains, Hokonui Hills, Ben Lomond, and the Routeburn, Makarora, and Hollyford Valleys.

Mr. J. Crosby Smith has also done much work in Otago, and has published an account of Lake Hauroko district and a list of the plants of Southland.

Professor Arnold Wall has collected assiduously for a number of years. His publications (Trans. N.Z. Inst.) include an interesting account of the distribution of *Senecio saxifragoides* and *S. lagopus* on Banks Peninsula (Trans. N.Z. Inst., vol. 50).

Other contributions by investigators working in New Zealand include (Trans. N.Z. Inst.) an account of the vegetation of Westport district by Mr. W. Townson, Pteridophytes of Banks Peninsula by Mr. W. Martin, the flora of Mongonui County by Mr. H. Carse, and the grasses of Tutira by Mr. H. Guthrie-Smith.

Lists of plants have been separately published by Mr. W. Martin for the neighbourhood of Dunedin, Professor C. Chilton for Riccarton Bush, Christchurch, and Professor A. Wall for the vicinity of Christchurch.

Foreign workers who have included in their publications New Zealand material are—Dr. G. Beauverd, on Compositae (Bull. Soc. Gen.); Dr. G. Bitter, on *Acaena;* Dr. A. Thellung, on *Lepidium;* and the contributors to "Das Pflanzenreich."

ECOLOGICAL BOTANY.

Foremost among the publications dealing with the ecological aspects of the plants of New Zealand are the writings of Dr. L. Cockayne. Of a general nature is his article entitled "Observations concerning Evolution derived from Ecological Studies in New Zealand" (Trans. N.Z. Inst., vol. 44). Other articles in the Transactions describe the plant formations of Open Bay Islands, Poor Knights Islands, Mount Fyffe, and, in collaboration with Mr. C. E. Foweraker, the vegetation of the Cass Biological Station, and with

Mr. R. M. Laing, that of the Mount Arrowsmith district. The vegetation of the Subantarctic Islands of New Zealand (other than Campbell Island) was described in Volume I of the "Subantarctic Islands of New Zealand," 1909. A series of parliamentary papers issued by the Lands Department covered botanical surveys of Kapiti Island, Tongariro National Park, Stewart Island, Waipoua Kauri Forest, and the sand-dune areas of New Zealand. An account of the coastal vegetation appeared in the "Transactions of the New Zealand Institute," vol. 39. These studies in the ecological botany of New Zealand culminated in the issue of a volume in Engler and Drude's "Die Vegetation der Erde" in 1921. Dr. Cockayne's book, entitled "The Vegetation of New Zealand," formed No. XIV of the series, contained a general account of the vegetation of New Zealand and the outlying islands, together with a summary of the geographical relationships of the flora, and was illustrated with sixty-five plates, in addition to text figures and maps.

Besides publications of a technical nature, Dr. Cockayne has issued in book form popular accounts of the vegetation of New Zealand. His "New Zealand Plants and their Story" has passed through two editions, and a third is now in the Press. In this connection may also be mentioned his recently issued handbook "The Cultivation of New Zealand Plants."

Other writers who have contributed to our knowledge of the plant formations of New Zealand by publishing descriptions of vegetation are Mr. R. M. Laing, on Campbell Island (Subantarct. Is. N.Z.); Mr. E. Phillips Turner, on the Waimarino district (parliamentary paper); and Mr. D. L. Poppelwell, on the Garvie Mountains, Ruggedy Mountains, Codfish Island, and Breaksea Islands (Trans. N.Z. Inst.). My own papers on the Kermadec Islands (Trans. N.Z. Inst.) and White Island (Jour. Linn. Soc. Bot.) may be mentioned here.

A volume by Hon. G. M. Thomson, issued under the title of "A New Zealand Naturalist's Calendar," contains many interesting observations on native plants, while a paper on the role of tree-ferns in the forest has been published by Miss A. Pope (N.Z. Jour. Sci. & Tech., vol. 6).

Professor D. H. Campbell has published a general description of the vegetation of New Zealand from notes collected during a visit in 1922 (Amer. Jour. Bot., vol. 10).

Ecological papers of economic interest include a series by Dr. Cockayne on the montane tussock grasslands of New Zealand, being the results of systematic experiments (N.Z. Jour. Agr.); an article by Mr. A. H. Cockayne on the same subject (Trans. N.Z. Inst., vol. 48); the series of papers on New Zealand grasslands, by Mr. E. Bruce Levy (N.Z. Jour. Agr.); and an account of the flax, *Phormium tenax*, by Mr. E. A. Atkinson (Dept. Agr. Bull. 95).

PLANT ANATOMY.

The period 1905–24 has been marked by the issue of a number of papers describing the minute structure of New Zealand plants. These are all of very great importance from an ecological standpoint, and in not a few cases are of great taxonomic value. Many of the papers are based on theses of University students.

Foremost in the matter of importance, both from an ecological and taxonomic point of view, is the series of papers on New Zealand Pteridophytes, published by Rev. Dr. J. Holloway. The genus *Lycopodium* has

been investigated from many points of view, and the prothallus of *Tmesipterus* has been described. Later contributions from Dr. Holloway deal with the ecology and distribution of the Hymenophyllaceae (Trans. N.Z. Inst.).

The Pteridophytes have also received attention from Mr. G. B. Stephenson, on young stages of *Dicksonia* and *Cyathea* (Trans. N.Z. Inst., vol. 40); and Miss K. V. Edgerley, on the prothallia of *Lycopodium* (Trans. N.Z. Inst., vol. 47).

The Gymnosperms have been investigated by Miss E. M. Griffen, on the development of Conifer leaves (Trans. N.Z. Inst., vol. 40), and Dr. J. S. Yeates, on root-nodules in New Zealand pines (N.Z. Jour. Sci. & Tech., vol. 6).

The following authors have contributed to the "Transactions of the New Zealand Institute" papers in which the anatomy of New Zealand flowering-plants is described: Miss N. A. R. Greensill, leaves of *Coprosma*; Miss A. C. Finlayson, stems of leafless plants; Miss E. M. Herriott, plants of the southern islands; Miss B. D. Cross, Halophytes; Miss A. F. Ironside, New Zealand Piperaceae; Miss F. W. Cooke, *Salicornia australis*; Miss E. S. Pegg, sand-dune plants; Miss L. A. Suckling, trees and shrubs of the Port Hills, Christchurch; Miss E. M. Pigott, *Nothopanax arboreum*; Miss M. W. Betts, plants from the peridotite belt, Nelson, and rosette plants from the Cass district; Mr. J. W. Bird, lianes of Canterbury Plains forest; Mr. C. E. Foweraker, mat and cushion plants of Cass River bed.

Outside New Zealand, Dr. H. Hauri has published descriptions of New Zealand cushion plants (Bot. Centrabl., vol. 33). Mr. R. S. Adamson has described the anatomy of the leaves of several species of *Veronica* (Jour. Linn. Soc., vol. 40); Professor F. O. Bower, in his studies on the phylogeny of the Filices (Ann. Bot., vol. 28) dealt with several New Zealand species; Dr. H. Hauri and D. C. Schoeter have dealt with a number of New Zealand cushion plants; and Dr. K. Goebel has described the juvenile forms of New Zealand plants.

EVOLUTION OF SPECIES AND GEOGRAPHICAL DISTRIBUTION.

Dr. Cockayne's paper previously mentioned, "Observations concerning Evolution derived from Ecological Studies in New Zealand," deals with such topics as variation, mutation, epharmony, hybridization, struggle for existence, and distribution. The discovery of hybrids in the genus *Nothofagus* was recorded in N.Z. Jour. Agr., vol. 23, while the whole question of hybridization in the New Zealand flora has been treated more fully in the "New Phytologist," vol. 22, 1923.

Dr. J. C. Willis, in developing his age and area theory, contributed a series of papers to the "Annals of Botany." Several of these dealt with New Zealand and the outlying islands and are incorporated in his book "Age and Area," published in 1922.

Dr. C. Skottsberg contributed to the "Plant World," vol. 18, 1915, a paper on the relations between the floras of New Zealand and subantarctic America.

Distribution within New Zealand has been dealt with by Dr. Cockayne in several of his works and, as a separate paper, in the Cawthron Lecture for 1919, published by the Cawthron Institute.

INTRODUCED PLANTS.

Hon. G. M. Thomson has summarized what is known on naturalized plants in New Zealand in his work on the "Naturalization of Animals and Plants in New Zealand," published in 1922.

Some interesting information regarding the spread of introduced plants is given in "Tutira" by Mr. H. Guthrie-Smith, while Dr. H. H. Allan has recorded the establishment of *Spartina* grass (N.Z. Jour. Sci. & Tech., vol. 6).

CHEMISTRY OF THE NEW ZEALAND FLORA.

A certain amount of investigation has been carried out in the chemistry of native plants. Mr. B. C. Aston has studied various tans, dyestuffs, oils, alkaloids, and poisonous properties, including the dyes obtained from *Coprosma*, the oil of *Tetrapathaea*, and the alkaloids of the pukatea.

Professor T. H. Easterfield and his collaborators have investigated the genus *Podocarpus;* Mr. Roy Gardner has written a general account and studied the essential oil of *Leptospermum;* Mr. Goudie has described the essential oils of *Libocedrus* and *Dacrydium;* Mr. Perkin, the colouring-matter of the puriri; and Messrs. W. F. Short and C. W. Johnson, the essential oil of *Leptospermum*.

LIST OF THE PUBLISHED WORKS OF Mr. T. F. CHEESEMAN.

I. FLORAS OF NEW ZEALAND.

Manual of the New Zealand Flora. pp. xxxvi + 1199. 1906.
Manual of the New Zealand Flora. pp. xliv + 1163. 1925.
Illustrations of the New Zealand Flora. 2 vols. 250 plates with letterpress. 1914. (Assisted by W. B. Hemsley.)

II. FLORAS OF SMALLER AREAS.

(1.) New Zealand.

On the Flora of the Kermadec Islands; with Notes on the Fauna. *Trans. N.Z. Inst.*, vol. 20, pp. 151–181. 1888.
Notes on the Three Kings Islands. *Trans. N.Z. Inst.*, vol. 20, pp. 141–150. 1888.
Further Notes on the Three Kings Islands. *Trans. N.Z. Inst.*, vol. 23, pp. 408–424. 1891.
On the Flora of the North Cape District. *Trans. N.Z. Inst.*, vol. 29, pp. 333–385. 1897.
On the Botany of the Titirangi District of the Province of Auckland. *Trans. N.Z. Inst.*, vol. 4, pp. 270–284. 1872.
Rangitoto Island and its Vegetation. *Handb. Sci. Visitors*, pp. 6–7, 1914; and *N.Z. Nature Notes*, pp. 20–21, 1922.
Some Features of the Auckland Flora. *Handb. Sci. Visitors*, pp. 8–12, 1914; *N.Z. Nature Notes*, pp. 22–26, 1922; and *N.Z. Jour. Sci. & Tech.*, vol. 5, pp. 166–168, 1922 (The Kauri Forest).
On the Botany of the Pirongia Mountain. *Trans. N.Z. Inst.*, vol. 12, pp. 317–323. 1880.
Contributions to a Flora of the Nelson Provincial District. *Trans. N.Z. Inst.*, vol. 14, pp. 301–329. 1882.
On the Systematic Botany of the Islands to the South of New Zealand. *Subant. Is. N.Z.*, vol. 2, pp. 389–471. 1909.
The Vascular Flora of Macquarie Island. *Rept. Austr. Ant. Exp.*, Ser. 3, vol. 7, pt. 3, 63 pp. 1919.

(2.) Rarotonga.

The Flora of Rarotonga, the Chief Island of the Cook Group. *Trans. Linn. Soc.*, Ser. 2. Bot., vol. 6, pt. 6, pp. 261–313. 1903.

III. PAPERS ON NEW ZEALAND INDIGENOUS PLANTS: DESCRIPTIVE AND GEOGRAPHICAL.

(1.) Systematic.

Notice of the Discovery of *Asplenium japonicum*, a Fern new to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 22, pp. 448–449. 1890.
Description of a New Species of *Polypodium*. *Trans. N.Z. Inst.*, vol. 10, pp. 356–357. 1878.
Description of a New Species of *Hymenophyllum*. *Trans. N.Z. Inst.*, vol. 8, pp. 330–331. 1876.
The Age and Growth of the Kauri. *Trans. N.Z. Inst.*, vol. 46, pp. 9–19. 1914.
Notice of the Occurrence of the Genus *Kyllinga* in New Zealand. *Trans. N.Z. Inst.*, vol. 11, pp. 434–435. 1879.
A Revision of the New Zealand Species of *Carex*. *Trans. N.Z. Inst.*, vol. 16, pp. 414–442. 1884.
Additional Notes on the Genus *Carex*. *Trans. N.Z. Inst.*, vol. 24, pp. 413–416. 1892.

On the Occurrence of the Genus *Sporadanthus* in New Zealand. *Trans. N.Z. Inst.*, vol. 12, pp. 324–325. 1880.
Notice of the Occurrence of *Juncus tenuis* Willd. in New Zealand. *Trans. N.Z. Inst.*, vol. 11, pp. 433–434. 1879.
Notice of the Discovery of a Species of *Burmanniaceae*, a Family new to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 41, pp. 140–143. 1909.
On *Pterostylis squamata* in New Zealand. *Trans. N.Z. Inst.*, vol. 7, pp. 352–353. 1875.
Description of a New Species of *Corysanthes*. *Trans. N.Z. Inst.*, vol. 31, pp. 351–352. 1899.
Notice of the Occurrence of *Hydatella*, a Genus new to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 39, pp. 433–434. 1907.
Notice of the Discovery of the Genus *Rhagodia* in New Zealand. *Trans. N.Z. Inst.*, vol. 16, pp. 408–409. 1884.
Description of a New Species of *Loranthus*. *Trans. N.Z. Inst.*, vol. 13, pp. 296–297. 1881.
On the Occurrence of the Australian Genus *Poranthera* in New Zealand. *Trans. N.Z. Inst.*, vol. 11, pp. 432–433. 1879.
Notice of the Occurrence of *Leucopogon Richei* R. Br. on the Mainland of New Zealand. *Trans. N.Z. Inst.*, vol. 42, pp. 214–215. 1910.
Notes on *Aciphylla;* with Descriptions of New Species. *Trans. N.Z. Inst.*, vol. 47, pp. 39–44. 1915.
Notes on *Pittosporum Dallii*. *Trans. N.Z. Inst.*, vol. 46, pp. 19–20. 1914.
Notes on *Pittosporum obcordatum*. *Trans. N.Z. Inst.*, vol. 39, pp. 435–439. 1907.
On the New Zealand Species of *Coprosma*. *Trans. N.Z. Inst.*, vol. 19, pp. 218–252. 1887.
Description of Three New Species of *Coprosma*. *Trans. N.Z. Inst.*, vol. 18, pp. 315–317. 1886.
Description of a New *Celmisia*. *Trans. N.Z. Inst.*, vol. 46, p. 21. 1914.
Note on *Helichrysum fasciculatum* Buchanan. *Proc. N.Z. Inst.*, 1911, pp. 24–25.
Description of a New Species of *Senecio*. *Trans. N.Z. Inst.*, vol. 7, p. 348. 1875.

(2.) Miscellaneous.

On some Hitherto Unrecorded Plant-stations. *N.Z. Jour. Sci. & Tech.*, vol. 1, pp. 202–205. 1882.
On some Additions to the Flora of New Zealand. *Trans. N.Z. Inst.*, vol. 14, pp. 299–301. 1882.
On some Recent Additions to the Flora of New Zealand. *Trans. N.Z. Inst.*, vol. 15, pp. 298–301. 1883.
Additions to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 16, pp. 409–413. 1884.
New Species of Plants. *Trans. N.Z. Inst.*, vol. 17, pp. 235–236. 1885.
On some Recent Additions to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 24, pp. 409–412. 1892.
On some Additions to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 28, pp. 534–537. 1896.
On some Plants new to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 29, pp. 390–393. 1897.
Some Recent Additions to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 33, pp. 312–313. 1901.
Some Recent Additions to the Flora of New Zealand. *Trans. N.Z. Inst.*, vol. 42, pp. 216–218. 1910.
New Species of Plants. *Trans. N.Z. Inst.*, vol. 43, pp. 175–178. 1911.
A New Genus and some New Species of Plants. *Trans. N.Z. Inst.*, vol. 44, pp. 159–162. 1912.
Some New Species of Plants. *Trans. N.Z. Inst.*, vol. 45, pp. 93–96. 1913.
New Species of Flowering-plants. *Trans. N.Z. Inst.*, vol. 47, pp. 45–47. 1915.
New Species of Plants. *Trans. N.Z. Inst.*, vol. 48, pp. 210–215. 1916.
Some Additions to the New Zealand Flora. *Trans. N.Z. Inst.*, vol. 51, pp. 92–95. 1919.
New Species of Flowering-plants. *Trans. N.Z. Inst.*, vol. 53, pp. 423–425. 1921.
New Species of Flowering-plants. *Trans. N.Z. Inst.*, vol. 54, pp. 565–569. 1923.
Contributions to a Fuller Knowledge of the Flora of New Zealand. *Trans. N.Z. Inst.* No. 1, vol. 39, pp. 439–450. 1907. No. 2, vol. 40, pp. 270–285. 1908. No. 3, vol. 41, pp. 200–213. 1909. No. 4, vol. 43, pp. 178–186. 1911. No. 5, vol. 46, pp. 1–9. 1914. No. 6, vol. 51, pp. 85–92. 1919, No. 7, vol. 52, pp. 9–16. 1920.

(3.) Fertilization of New Zealand Plants.

On the Fertilization of *Acianthus* and *Cystostilis*. *Trans. N.Z. Inst.*, vol. 7, pp. 349–352. 1875.
On the Fertilization of the New Zealand Species of *Pterostylis*. *Trans. N.Z. Inst.*, vol. 5, pp. 352–357, pl. 20. 1873.
On the Fertilization of *Thelymitra*. *Trans. N.Z. Inst.*, vol. 13, pp. 291–296. 1881.
Notes on the Fertilization of *Knightia*. *N.Z. Jour. Sci. & Tech.*, vol. 1, pp. 173–175. 1882.
Notes on the Fertilization of *Knightia*. *Rept. A.A.A.S.*, vol. 2, pp. 473–476. 1890.
On the Fertilization of *Selliera*. *Trans. N.Z. Inst.*, vol. 9, pp. 542–545. 1877.
Notes on the Fertilization of *Glossostigma*. *Trans. N.Z. Inst.*, vol. 10, pp. 353–356. 1878.

IV. INTRODUCED PLANTS.

The Naturalized Plants of the Auckland Provincial District. *Trans. N.Z. Inst.*, vol. 15 pp. 268–298. 1883.
Notice of the Establishment of *Vallisneria spiralis* in Lake Takapuna, together with some Remarks on its Life-history. *Trans. N.Z. Inst.*, vol. 29, pp. 386–390. 1897.
On the Occurrence of *Ottelia* in New Zealand. *Trans. N.Z. Inst.*, vol. 31, pp. 350–351. 1899.

V. POLYNESIAN FOOD PLANTS.

Notes on the Cultivated Food Plants of the Polynesians, with Special Reference to the Ti Pore (*Cordyline terminalis*). *Trans. N.Z. Inst.*, vol. 33, pp. 306–311. 1901.

VI. BOTANICAL NOMENCLATURE.

Notes on Botanical Nomenclature; with Remarks on the Rules adopted by the International Botanical Congress of Vienna. *Trans. N.Z. Inst.*, vol. 40, pp. 447–465 1908.

VII. ETHNOLOGY.

Notes on certain Maori Carved Burial-chests in the Auckland Museum. *Trans. N.Z. Inst.*, vol. 39, pp. 451–456. 1907.
Maori Burial-chests. *Man.*, vol. 18, p. 81. 1918.

VIII. ZOOLOGY.

(1.) Turbellaria.

On Two New Planarians from Auckland Harbour. *Trans. N.Z. Inst.*, vol. 15, pp. 213–214. 1883.

(2.) Mollusca.

On the Mollusca of the Vicinity of Auckland. *Trans. N.Z. Inst.*, vol. 19, pp. 161–176. 1887.
On the Mollusca of Auckland Harbour. *Trans. N.Z. Inst.*, vol. 8, pp. 304–311. 1876.
On some New Species of Nudibranchiate Mollusca. *Trans. N.Z. Inst.*, vol. 13, pp. 222–224. 1881.
On Two Species of Nudibranchiate Mollusca. *Trans. N.Z. Inst.*, vol. 14, pp. 213–215. 1882.
On a New Species of *Chromodoris*. *Trans. N.Z. Inst.*, vol. 18, p. 137. 1886.
Descriptions of Three New Species of Opisthobranchiate Mollusca, from New Zealand. *Trans. N.Z. Inst.*, vol. 11, pp. 378–380, pl. 16. 1879.
On a New Genus of Opisthobranchiate Mollusca. *Trans. N.Z. Inst.*, vol. 13, p. 224. 1881.

(3.) Fishes.

Notes on the Swordfish (*Ziphias gladius*). *Trans. N.Z. Inst.*, vol. 8, pp. 219–220. 1876.
Notice on the Occurrence of the Basking Shark (*Selache maxima* L.) in New Zealand. *Trans. N.Z. Inst.*, vol. 23, pp. 126–127. 1891.

(4.) Reptiles.

On the Occurrence of the Luth, or Leathery Turtle, on the Coasts of New Zealand. *Trans. N.Z. Inst.*, vol. 25, pp. 108–110. 1893.

Notes on the Occurrence of certain Marine Reptilia in New Zealand Waters. *Trans. N.Z. Inst.*, vol. 40, pp. 267–269. 1908.

(5.) Birds.

On some Birds from the Kermadec Islands. *Trans. N.Z. Inst.*, vol. 21, pp. 121–124. 1889.

On the Birds of the Kermadec Islands. *Trans. N.Z. Inst.*, vol. 23, pp. 216–226. 1891.

Notice of the Capture of a Specimen of the Shy Albatross (*Diomedea cauta*) near Auckland. *Trans. N.Z. Inst.*, vol. 21, pp. 125–126. 1889.

Notice of the Occurrence of the Lesser Frigate-bird (*Fregata ariel*) in the North Auckland District. *Trans. N.Z. Inst.*, vol. 40, pp. 265–266. 1908.

Notice of the Occurrence of the Eastern Golden Plover (*Charadrius fulvus*) in the Auckland District. *Trans. N.Z. Inst.*, vol. 14, pp. 264–265. 1882.

Notice of the Occurrence of the Australian Snipe (*Gallinago australis*) in New Zealand. *Trans. N.Z. Inst.*, vol. 31, pp. 105–106. 1899.

Notice of the Occurrence of the Australian Roller (*Eurystomus pacificus*) in New Zealand. *Trans. N.Z. Inst.*, vol. 14, pp. 265–266. 1882.

(6.) Mammals.

Notes on the New Zealand Bats. *Trans. N.Z. Inst.*, vol. 25, pp. 218–222. 1894.

IX. MISCELLANEOUS.

Presidential Address to Board of Governors of N.Z. Institute, 1912. *Proc. N.Z. Inst.*, 1911, pp. 75–79. 1912.

Presidential Address to Board of Governors of N.Z. Institute, 1913. *Trans. N.Z. Inst.*, vol. 45, pp. 420–422. 1913.

The First Fifty Years of the Auckland Institute and Museum and its Future Aims: A Jubilee Sketch. pp. 1–21. 1917.

Auckland Museum. *Handb. Sci. Visitors*, pp. 7–8, 1914, and *N.Z. Nature Notes*, pp. 26–27, 1922.

MANUAL

OF THE

NEW ZEALAND FLORA.

Family 1. **FILICES.**

PERENNIAL or very rarely annual plants, usually herbaceous but sometimes arboreous (tree-ferns). Stems generally reduced to a rhizome, which may be short and tufted, or long and creeping or climbing; or, in the case of tree-ferns, produced into an erect caudex or trunk. Leaves (*fronds*) either crowded at the end of the rhizome or distantly placed along it, continuous with the rhizome or jointed to it, sometimes simple and entire, but usually more or less deeply pinnately lobed or divided and frequently repeatedly so, more rarely dichotomously branched; always circinate in vernation with the exception of the *Ophioglossaceae*. Spore-cases or *sporangia* usually arranged in groups (*sori*) on the under-surface or margins of the fertile fronds, which are either similar to the sterile fronds, or narrower and more contracted, the divisions sometimes becoming linear and spike-like. Sori very various in size and shape and position, naked or covered when young by the recurved margin of the frond or by a special involucre (*indusium*). Sporangia many or rarely few in a sorus, often mixed with jointed hairs or scales, stalked or sessile, usually furnished with a complete or incomplete ring or *annulus*, dehiscing by a transverse or vertical slit, free or rarely coherent into a compound sporangium (*synangium*). Spores numerous, bilateral or tetrahedral.

Ferns constitute one of the largest and most generally distributed of the families of plants, and are found in all quarters of the world, although most abundant in warm and moist climates. It is difficult to estimate the number of species, on account of the divergent views of authors, but probably from 5000 to 5500 would be a fair estimate. In the first edition of this book I followed the limitation of the genera proposed in Hooker and Baker's "Synopsis Filicum," that being the arrangement adopted in Hooker's "Handbook," Bentham's "Flora Australiensis," and other colonial Floras; and the one then acquiesced in by most English systematists. But now pteridologists as a whole adopt a much larger number of genera, with a somewhat different sequence. And it must be admitted that *Polypodium*, *Nephrodium*, *Asplenium*, and other genera, as defined in the "Synopsis Filicum," are for the most part artificial assemblages of species, possessing very diverse characters and relationships. But although it is comparatively easy to separate a group here and there as being undoubtedly worthy of generic rank; it is admittedly a matter of great difficulty to prepare good and natural generic subdivisions for the whole family. The most satisfactory classification yet propounded is that given by Diels and others in Engler and Prantl's "Die Naturlichen Pflanzenfamilien," where the class Filicales is divided into 12 families and 140 genera, against the 75 genera adopted in the "Synopsis Filicum." After some consideration, I have decided to follow this classification, as restated and slightly amended by Christensen in his "Index Filicum" (1906).

The development of ferns can only be briefly alluded to here. In germination the spore produces a small flattened or rarely filamentous prothallium, usually containing abundant chlorophyll, but without vascular tissue. It becomes quite free from the spore, but is of comparatively short duration. On the under-surface of the prothallium the reproductive organs are formed. The male organs are called antheridia, and consist of minute subglobose bodies each containing numerous motile cells known as spermatozoids, resembling spirally coiled filaments, pointed at one end and bearing numerous cilia. The female organs, or archegonia, are flask-shaped bodies partly sunk in the tissue of the prothallium, each containing a single free cell called the oosphere. Fertilization is effected by the entrance of spermatozoids into the cavity of the archegonium, and by the fusion of one of them with the oosphere. The oosphere then gradually develops into a young plant.

Prior to the publication of the first edition of this work several pamphlets or books dealing with the Ferns of the Colony have appeared. The most important are Mr. G. M. Thomson's "Ferns and Fern Allies of New Zealand" and Mr. H. C. Field's "Ferns of New Zealand." Both of these contain much interesting and valuable matter, and should be consulted by all students of the family. An excellently illustrated book on the Ferns of the Dominion, prepared by Mr. H. Dobbie, has also appeared wh le this acco nt was being written.

Suborder I. HYMENOPHYLLACEAE. *Sori always marginal, enclosed within a cup-shaped or urceolate entire or 2-valved indusium. Sporangia sessile or shortly stalked, arranged on a short or long columnar receptacle, girt by a complete horizontal or oblique ring. Fronds membranous and translucent (except in* Loxsoma*).*

Fronds membranous and translucent. Indusium deeply 2-valved — 1. HYMENOPHYLLUM.
Fronds membranous and translucent. Indusium urceolate or trumpet-shaped, entire or shortly 2-lobed .. .. .. — 2. TRICHOMANES.
Fronds coriaceous, opaque. Indusium urceolate, entire .. — 3. LOXSOMA.

Suborder II. CYATHEACEAE. *Sori dorsal or marginal, naked or furnished with an indusium. Sporangia sessile or shortly stalked, arranged on a cushion-like receptacle, girt by a complete vertical or somewhat oblique ring. Stem often arboreous.*

Indusium 2-valved, the upper valve continuous with the margin of the frond .. .. — 4. DICKSONIA.
Indusium globose, covering the young sorus, but soon bursting at the summit and persistent as a shallow cup surrounding the sorus at the base .. .. — 5. CYATHEA.
Indusium never covering the sorus, small, half cup-shaped or semicircular, one-sided, not forming a complete ring round the base of the sorus .. .. — 6. HEMITELIA.
Indusium altogether wanting .. .. — 7. ALSOPHILA.

Suborder III. POLYPODIACEAE. *Sori dorsal or marginal, naked or furnished with an indusium. Sporangia with a short or long stalk, girt by an incomplete vertical ring, bursting transversely. Habit various.*

* Sori dorsal, remote from the margin of the frond. Indusium hooded or globose or reniform, opening all round its margin.

Indusium hooded, ovate-deltoid, attached by a broad base .. — 8. CYSTOPTERIS.
Indusium orbicular and peltate .. .. — 9. POLYSTICHUM.
Indusium reniform, attached by the sinus. Fronds usually 2–4-pinnate; pinnae not articulate on the rhachis .. .. — 10. DRYOPTERIS.
Indusium wanting. Fronds pinnate; pinnae articulate on the rhachis .. .. — 11. ARTHROPTERIS.
Indusium present, usually reniform. Fronds pinnate, articulated on the rhachis .. .. — 12. NEPHROLEPIS.

** Sori marginal. Indusium opening outwards, or towards the margin of the frond.

Indusium ovate, attached by a broad base, its free margin scalloped .. .. — 13. LEPTOLEPIA.
Indusium cup-shaped, attached by both base and sides .. — 14. DAVALLIA.
Sori linear. Indusium 2-valved; upper valve formed by the altered margin of the frond .. .. — 15. LINDSAYA.

*** Sori linear or oblong, dorsal or submarginal. Indusium the same shape as the sorus; opening inwards (towards the costa).

Sori short, oblong, situated on a veinlet. Indusium inflated, straight or arcuate .. .. — 16. ATHYRIUM.

Sori linear, placed on a vein. Indusium double; one opening towards the midrib, the other away from it .. .. 17. DIPLAZIUM.
Sori linear, attached to a vein. Indusium single, opening towards the midrib .. .. 18. ASPLENIUM.
Sori long, linear, attached to transverse veinlets running parallel to the midrib. Indusium opening towards the midrib .. 19. BLECHNUM.
Sori short, oblong, on transverse veins joining the main veins. Indusium opening towards the midrib .. .. .. 20. DOODIA.

**** Sori marginal. Indusium composed of the more or less modified margin of the frond, which is reflexed over the sori, thus opening inwards.

Sori oblong or linear, simple or forked, often confluent. Indusium wanting .. .. 21. GYMNOGRAMME.
Sori confluent into a linear band along the margin of the pinnae. Indusium continuous .. .. 22. PELLAEA.
Sori oblong, ultimately confluent, often concealed by the reflexed but barely altered margin of the frond .. .. .. 23. NOTHOCHLAENA.
Sori subglobose or oblong, often confluent into linear masses. Indusium composed of the modified and reflexed margin of the frond .. .. 24. CHEILANTHES.
Sori globose, distinct, in the notches of the ultimate divisions of the frond. Indusium a modified and reflexed portion of the margin of the frond .. .. 25. HYPOLEPIS.
Sori reniform or globose or oblong. Indusium an altered and reflexed lobe or tooth of the frond, bearing the sorus on its under-surface .. .. 26. ADIANTUM.
Sori marginal, linear, continuous. Indusium always single. Veins free or anastomosing. Spores tetrahedral .. .. 27. PTERIS.
Sori marginal, linear, continuous. Indusium always single. Veins free or anastomosing. Habit of *Pteridium*. Spores bilateral .. .. 28. HISTIOPTERIS
Sori marginal, linear, continuous. Indusium double, outer the reflexed margin of the frond, inner arising from the receptacle. Spores tetrahedral .. .. 29. PTERIDIUM.
Sori marginal, linear, continuous. Indusium usually double. Fronds more finely cut than in *Pteridium*. Spores bilateral.. 30. PAESIA.

***** Sori dorsal, remote from the margin of the frond. Indusium wanting. Fronds articulated on the rhizome (Eremobryoid).

Fronds simple or compound, glabrous; or indumentum, if present, composed of simple hairs or scales .. .. .. 31. POLYPODIUM.
Fronds simple, sometimes dimorphous, under-surface covered with matted stellate hairs .. .. 32. CYCLOPHORUS.

Suborder IV. GLEICHENIACEAE. *Sori dorsal, naked, of few (2–6) sporangia; receptacle not elevated. Sporangia sessile or nearly so, splitting vertically, surrounded by a complete transverse ring.*

Fronds dichotomously forked; ultimate branches pinnately divided .. .. 33. GLEICHENIA.

Suborder V. SCHIZÆACEAE. *Sporangia crowded, not collected into distinct sori, sessile or nearly so, with a complete transverse ring just below the apex, splitting vertically. Fertile portions of the frond much modified.*

Fronds simple or forked or flabellately divided, without an expanded lamina. Sporangia in 2–4 rows on the under-surface of short linear fertile pinnae terminating the fronds.. .. 34. SCHIZÆA.
Fronds very long, climbing; primary pinnae dichotomously or pinnately divided. Sporangia in 2 rows on the under-surface of contracted fertile pinnules .. .. 35. LYGODIUM.

Suborder VI. OSMUNDACEAE. *Sori irregular, distinct or confluent, dorsal; indusium wanting. Sporangia sessile or nearly so, splitting vertically; ring rudimentary, placed just below the apex.*

Fronds coriaceous, dense and opaque .. .. .. 36. TODEA.
Fronds membranous, thin and translucent .. .. .. 37. LEPTOPTERIS

Suborder VII. MARATTIACEAE. *Sori distinct, dorsal. Sporangia sessile, without any ring, coriaceous, splitting vertically or opening by a pore at the apex, usually cohering in concrete masses called synangia.*

Rhizome large, tuberous. Fronds large, 2–3-pinnate .. .. 38. MARATTIA.

Suborder VIII. OPHIOGLOSSACEAE. *Sporangia globose, coriaceous, sessile, without any ring, dehiscing by a transverse or vertical slit, crowded on a linear spike or on the branches of a panicle. Fronds not circinate in vernation.*

Sterile frond simple and entire. Sporangia on a linear spike .. 39. OPHIOGLOSSUM.
Sterile frond pinnate or 2–4-pinnate. Sporangia on the linear branches of a panicle .. .. 40. BOTRYCHIUM.

1. **HYMENOPHYLLUM** Linn.

Usually small and sometimes minute ferns. Rhizome slender, creeping, often much branched and matted. Fronds simple or more generally compound, delicately membranous, often pellucid, usually of a single layer of cells; segments entire or toothed at the margin, with a stout central costa. Sori marginal, terminal or lateral, more or less immersed in the frond or quite free, always terminating a vein or costa. Indusium cup-shaped, more or less deeply 2-lipped or 2-valved, sometimes to the base, of almost the same texture as the frond, margins of the lips entire or toothed or fringed. Receptacle linear or oblong, not exserted beyond the indusium. Sporangia sessile or nearly so, depressed, surrounded by a broad complete horizontal ring, bursting transversely.

One of the most beautiful of the genera of ferns, almost wholly confined to shaded localities, and remarkable for the filmy texture of the frond, a peculiarity which it shares with *Trichomanes* and *Leptopteris*. Species about 150, widely distributed in tropical climates and in the South Temperate Zone, especially abundant in New Zealand, rare in the North Temperate Zone. Of the 20 species found in New Zealand, 7 or perhaps 8 are endemic, the remainder are for the most part widely dispersed.

A. Euhymenophyllum. *Margin of the frond entire.*

* Fronds glabrous; or, if hairs are present, they are confined to the stipes, rhachis, and costae.

† Rhachis winged throughout; wing often decurrent down the stipes, sometimes to the base.

Fronds 1–4 in., pendulous, flaccid, 2-pinnatifid. Stipes capillary; rhachis often wingless below. Sori large, terminal, immersed; indusium orbicular .. .. 1. *H. rarum.*
Fronds 2–9 in., olive-green, 3-pinnatifid, sometimes with scattered hairs on the rhachis and stipes. Sori terminating short lateral segments, free; indusium broadly ovate .. 2. *H. sanguinolentum.*
Fronds 2–6 in., brownish-green, 3–4-pinnatifid; segments narrow, crowded. Stipes, rhachis, and costae usually villous. Sori numerous, terminal, free; indusium broadly ovate .. 3. *H. villosum.*
Fronds 3–9 in., triangular. Rhachis with a broad much-crisped wing decurrent almost to the base of the stipes. Sori terminal, free; indusium orbicular .. .. .. 4. *H. australe.*
Fronds 2–3 in., linear-oblong, dull dark-green. Rhachis with a broad flat wing decurrent almost to the base of the stipes. Sori terminal, free; indusium ovate, margins often jagged .. 5. *H. atrovirens.*
Rhizome short, bristly. Fronds 9–20 in., ovate-lanceolate, pale-green. Rhachis with a narrow flat wing decurrent down the stipes. Sori terminal, free; indusium orbicular .. .. 6. *H. pulcherrimum.*
Rhizome long, glabrous. Fronds 9–20 in., ovate-lanceolate; segments broad, flat. Rhachis with a narrow flat wing decurrent along the stipes. Sori terminal, immersed; indusium orbicular .. .. 7. *H. dilatatum.*

†† Rhachis winged only towards the top; lower part and stipes naked (often narrowly winged in *H. demissum*).

Fronds 4–12 in., ovate-deltoid, bright-green; stipes and rhachis glabrous. Sori terminal, free; indusium ovate .. .. 8. *H. demissum.*
Fronds 6–20 in., ovate-lanceolate, brownish-green; stipes and rhachis bristly. Sori terminal; indusium orbicular .. 9. *H. scabrum.*
Fronds 3–9 in., pale glistening-green; lower pinnae often flabellate. Stipes woolly at the base. Sori terminal, small; indusium broadly ovate or orbicular .. .. .. 10. *H. flabellatum.*
Fronds ½–1½ in., deltoid, very delicate. Stipes, rhachis, and costae with silky flexuous hairs. Sori terminal, small, partly immersed; indusium ovate-orbicular .. .. .. 11. *H. rufescens.*

** Fronds with the margins and both surfaces densely clothed with stellate hairs.

Fronds 2–6 in., oblong; rhachis broadly winged throughout, the wing decurrent along the upper part of the stipes. Sori terminal, immersed .. .. 12. *H. ciliatum.*
Fronds 2–10 in., oblong-lanceolate; rhachis winged only towards the top; stipes naked. Sori terminal, immersed .. 13. *H. ferrugineum.*
Fronds 2–8 in., linear-oblong, rigid and coriaceous, everywhere hidden by dense tomentum; rhachis not winged. Sori terminal, free .. .. 14. *H. Malingii.*

B. Leptocionium. *Margins of the frond spinulose-dentate.*

Fronds minute, ¼–1 in., simple or forked or digitately divided. Indusium with entire valves .. .. 15. *H. Cheesemanii.*
Fronds minute, ¼–1 in., pinnatifid. Sori solitary, free, terminating the main rhachis; indusium with the valves spinulose on the back and margins .. .. 16. *H. minimum.*
Fronds 1–4 in., pinnate; pinnae divided. Sori lateral, near the base of the pinnae, free; indusium with the valves smooth on the back, spinulose-dentate on the margins .. .. 17. *H. Tunbridgense.*
Fronds 1–4 in., pinnate; pinnae divided. Sori lateral, near the base of the pinnae, free; indusium with the valves smooth on the back; margins entire .. .. 18. *H. peltatum.*
Fronds 4–8 in., 3–4-pinnatifid. Sori lateral, near the base of the pinnae, free; indusium large, often decurved, obovoid; valves with entire margins .. .. 19. *H. multifidum.*
Fronds 6–12 in., 3–4-pinnatifid. Sori terminal, immersed in the tips of the segments; indusium ovate-orbicular, valves with entire margins .. .. 20. *H. bivalve.*

1. **H. rarum** *R. Br. Prodr.* (1810) 159.—A very delicate pale glistening-green pellucid species, forming matted patches on the trunks of trees or on rocks. Rhizomes creeping, much branched, very slender, wiry, black. Fronds very variable in size and shape, usually from 1–4 in. long, but sometimes dwarfed to ½ in., and occasionally lengthened out to 6 or 8 in., broadly oblong to linear-oblong, 2-pinnatifid, in large specimens pinnate at the base, pendulous, membranous, flaccid, quite glabrous. Stipes extremely slender, capillary, often half the length of the whole frond; main rhachis usually winged throughout. Pinnae close, often overlapping, once or twice forked or pinnatifid, rarely simple. Segments erecto-patent, ¼–½ in. long, $\frac{1}{10}$ in. broad, flat, obtuse, quite entire. Sori mostly near the summit of the frond, sunk in the tips of the segments. Indusium large, almost as broad as the segments, broadly rhomboid, divided half-way down, cuneate at the base: valves broad, rounded.—*Hook. Sp. Fil.* i (1846) 101; *Hook. f. Fl. Antarct.* i (1844) 105; *Fl. Nov. Zel.* ii (1855) 12; *Handb. N.Z. Fl.* (1864) 353; *Hook. and Bak. Syn. Fil.* (1873) 58; *Benth. Fl. Austral.* vii (1878) 705; *Thoms. N.Z. Ferns* (1882) 38; *Cheesem. Man. N.Z. Fl.* (1906) 930. H. semibivalve *Hook. and Grev. Ic. Fil.* (1829) t. 83; *A. Rich. Fl. Nouv. Zel.* (1832) 94; *A. Cunn. Precur.* (1836) n. 241;

Raoul Choix (1846) 39. H. imbricatum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 187.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: From Mangonui and Kaitaia southwards, not uncommon in forests. Sea-level to 3000 ft.

Taken in a broad sense, this is a widely distributed plant, found in Australia and Tasmania, Polynesia, Japan, South Africa and Mauritius, and extratropical South America. It is easily recognized by the extremely slender capillary stipes, pendulous pale glaucous-green fronds, broad flat entire segments, and large orbicular sori. When growing in exposed places it is often much dwarfed, with closely imbricating pinnae, constituting Colenso's *H. imbricatum*.

2. **H. sanguinolentum** *Swartz Syn. Fil.* (1806) 149.—Forming matted patches on the trunks or branches of trees or on rotten logs. Rhizome rather stout, creeping, much branched, usually bristly with reddish-brown hairs. Fronds erect or decurved, somewhat opaque, dull olive-green, reddish-brown when dry, 2-9 in. high, broadly ovate or oblong, 3-pinnatifid, glabrous or the stipes and rhachis with scattered red-brown hairs when young. Stipes rather stout, narrowly winged above; rhachis broadly winged throughout, stout, flexuose. Primary pinnae close or rather distant, spreading, rarely decurved; secondary short, deeply pinnatifid. Segments narrow-linear, obtuse, flat or the margins undulate. Sori mainly in the upper part of the frond, usually terminating short somewhat contracted lateral segments, quite free or very slightly sunk at the base. Indusium broader than the segment, broadly ovate or suborbicular, 2-valved to the base; valves obtuse, entire or slightly sinuate, often crested on the back.—H. polyanthos *Swartz Syn. Fil.* (1806) 149, *var.* sanguinolentum; *Hook. f. Fl. Nov. Zel.* ii (1855) 14; *Handb. N.Z. Fl.* (1864) 354; *Hook. and Bak. Syn. Fil.* 60; *Thoms. N.Z. Ferns*, 38; *Field N.Z. Ferns*, 58, t. 28, f. 7; *Cheesem. Man. N.Z. Fl.* (1906) 931. H. sanguinolentum *Swartz Syn. Fil.* (1806) 148, 376; *A. Rich. Fl. Nouv. Zel.* (1832) 93; *A. Cunn. Precur.* (1836) n. 234; *Raoul Choix* (1846) 38. H. lophocarpum *Col. in Trans. N.Z. Inst.* xvii (1885) 255. Trichomanes sanguinolentum *Forst. f. Prodr.* (1786) n. 465.

North and South Islands, Stewart Island, Auckland Islands: Abundant in forests throughout. Sea-level to 3000 ft.

One of the most abundant species of the genus in New Zealand. It stains paper brown when drying, and gives off a peculiar odour, which it often retains for years. The species, or allied forms, are found in almost all tropical countries, but apparently not in Australia.

3. **H. villosum** *Col. in Tasm. Journ. Nat. Sci.* ii (1844) 185.—Forming dense matted patches on the trunks of trees or amongst moss. Rhizome much branched, wiry, creeping. Fronds erect or decurved, opaque, dull brownish-green, 2–6 in. long, 1–2½ in. broad, broadly ovate to ovate-lanceolate, acuminate, 3–4-pinnatifid. Stipes 1–3 in. long, usually narrowly winged above, villous with scattered spreading hairs; rhachis narrowly winged throughout, rather slender, flexuous, more or less villous, as are the partial rhachides and costae. Primary pinnae closely placed, often overlapping, lanceolate-deltoid; secondary rhombic-ovate, again once or twice pinnatifid. Ultimate segments crowded, very narrow, linear, obtuse, flat. Sori numerous, terminating the segments, free. Indusium broadly ovate, obtuse or subacute, broader than the segments, 2-valved to the base; valves

smooth, entire.—*T. Kirk in Trans. N.Z. Inst.* x (1878) 395; *Bak. in Annals Bot.* v (1890–91) 192; *Thoms. N.Z. Ferns* (1882) 39; *Cheesem. Man. N.Z. Fl.* (1906) 931.

North Island: Auckland—Summit of Moehau (Cape Colville), *Adams!* Te Aroha Mountain, *T. F. C.;* Tarawera Mountain, *T. Kirk;* Ruatahuna, *Colenso!* Hawke's Bay—Tukituki River, *A. Hamilton!* Ruahine Mountains, *H. Hill!* Wellington—Tararua Range, *H. H. Travers!* South Island: Not uncommon in subalpine forests throughout, especially in Westland. Stewart Island: Mount Anglem, *T. Kirk.* Auckland Islands: *T. Kirk.* Usually from 2000–4500 ft., but descends almost to sea-level in Westland.

This was placed with *H. sanguinolentum* by Hooker, and is doubtless closely allied to it. But it differs markedly in the much more finely cut 4-pinnatifid fronds, in the villous stipes, rhachis, &c., in the much narrower segments, and in the smaller sori.

4. **H. australe** (*Willd. Sp. Plant.* v (1810) 527.—Forming matted patches on rocks or among moss, more rarely on the trunks of trees, pale-green when young, becoming lurid-green in age. Rhizome creeping, branched, wiry. Fronds erect or decurved, very membranous, 3–9 in. long, 1½–4 in. broad, triangular with usually a broad base, acuminate, quite glabrous, 2–3-pinnatifid. Rhachis with a broad much-crisped wing which extends almost to the base of the stipes. Primary pinnae ¾–2 in. long, rhomboidal-lanceolate, spreading, often decurved at the tips, deeply pinnatifid; secondary again pinnatifid or irregularly forked. Ultimate segments narrow-linear, obtuse, quite entire, more or less crisped, rarely flat. Sori usually numerous, terminal on the segments, free. Indusium orbicular or broadly ovate, usually broader than the segments, 2-valved to the base; valves broad, rounded, entire or slightly erose.—*Bak. in Annals Bot.* v (1890–91) 193; *Cheesem. Man. N.Z. Fl.* (1906) 932. H. javanicum *Spreng. Syst.* iv (1827) 132; *Hook. and Bak. Syn. Fil.* (1873) 60; *Thoms. N.Z. Ferns* (1882) 39; *Field N.Z. Ferns* (1890) 61, t. 15, f. 4. H. crispatum *Wall. Cat.* (1828) 169; *Hook. Sp. Fil.* i (1846) 105; *Hook. f. Fl. Nov. Zel.* ii (1855) 13; *Handb. N.Z. Fl.* (1864) 354. H. flexuosum *A. Cunn. Precur* (1836) n. 238; *Raoul Choix* (1846) 39.

North and South Islands, Stewart Island: Not uncommon in damp woods. Sea-level to 2000 ft.

A common plant in Tasmania, and from thence extending northwards to Malaya, India, and Ceylon. It is easily distinguished from the other New Zealand species by the broad conspicuously crisped wing of the rhachis and stipes.

5. **H. atrovirens** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 186.—Usually terrestrial. Rhizome slender, wiry, creeping. Fronds few, somewhat rigidly erect, membranous, dull dark-green, 2–6 in. high, ½–1 in. broad, linear-oblong or lanceolate, quite glabrous, 2-pinnatifid. Stipes about half the length of the frond, winged almost to the base; rhachis flexuose, winged throughout, wings flat, not crisped. Pinnae 5–10 on each side, alternate, the lowest usually the largest, ⅓–⅔ in. long, erecto-patent, irregularly pinnatifid. Segments simple or forked, linear, obtuse, flat, quite entire. Sori few, terminating the segments, quite free. Indusium small, ovate, 2-valved almost to the base, slightly broader than the segments; valves obtuse or subacute, entire or jagged.—*Cheesem. Ill. N.Z. Fl.* ii (1914) t. 235. H. javanicum *var.* atrovirens *Hook. and Bak. Syn. Fil.* (1873) 60. H. montanum *T. Kirk in Trans. N.Z. Inst.* x (1878) 394; *Thoms. N.Z. Ferns* (1882) 40; *Field N.Z. Ferns* (1890) 61, t. 28, f. 1.

North Island: Auckland—Bay of Islands, *Miss Clarke!* Whangarei, *T. F. C.*; ravines at Mamaku, near Rotorua, *J. Stewart!* Lake Waikaremoana, *Colenso!* South Island: Nelson—Blind Bay, *Kingsley*. Otago—Mountains at the head of Lake Wakatipu, *Mrs. Mason!* Sea-level to 2500 ft.

I have ventured to restore Mr. Colenso's *H. atrovirens* to the rank of a species, for although undoubtedly very close to *A. australe* it appears to differ sufficiently in the much smaller and narrower more sparingly divided frond, in the flat (not crisped) wings to the rhachis and stipes, and in the narrower segments and smaller ovate indusia. Mr. Kirk's *H. montanum* is clearly the same plant, with the indusia conspicuously jagged. Whether the Australian plant included under *atrovirens* by Baker is also identical I am unable to say, not having seen specimens.

6. **H. pulcherrimum** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 185.—Forming dense tufts on the branches and trunks of trees. Rhizome short, stout, densely clothed with shining red-brown bristly scales; rootlets woolly. Fronds very handsome, pale-green, erect or pendulous, 9–30 in. long including the stipes, 2–6 in. broad, ovate-lanceolate or linear-oblong, acuminate, membranous, flaccid, quite glabrous, 3–4-pinnatifid. Stipes 2–6 in. long, winged to the base; rhachis also with a narrow wing throughout its length, wings not crisped. Primary pinnae 1½–3 in. long, rhomboidal-lanceolate, 2-pinnatifid down to a narrowly winged flexuous rhachis. Ultimate segments simple or forked, linear, flat, obtuse or retuse, quite entire. Sori terminating short lateral segments, sometimes apparently axillary, quite free. Indusium orbicular, 2-valved to the base; valves convex, quite entire.—*Hook. Sp. Fil.* i (1846) 103, t. 37A; *Hook. f. Fl. Nov. Zel.* ii (1855) 13, t. 74; *Handb. N.Z. Fl.* (1864) 354; *Hook. and Bak. Syn. Fil.* (1873) 62; *Thoms. N.Z. Ferns* (1882) 41; *Field N.Z. Ferns* (1890) 60, t. 20, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 933.

North Island: Mountainous forests of the interior, from Te Aroha and Lake Waikaremoana southwards. South Island: Rare and local in Nelson, Marlborough, and Canterbury; abundant in Westland and Otago. Stewart Island: Paterson's Inlet, *T. Kirk!* Sea-level to 3000 ft.

A very distinct species, confined to New Zealand.

7. **H. dilatatum** *Swartz Syn. Fil.* (1806) 149.—Large, very handsome, bright-green, clothing the trunks of trees or rotten logs. Rhizome long, stout, wiry, glabrous. Fronds variable in size, usually 9–18 in. long including the stipes, but luxuriant specimens often reach 2 ft. or more, the smaller specimens erect or decurved, the larger usually pendulous, 3–6 in. broad, ovate or ovate-lanceolate to linear-oblong, membranous, 3-pinnatifid. Stipes 2–6 in. long, terete, wiry, narrowly winged almost to the base; rhachis winged throughout, the wing flat, not crisped. Primary pinnae 1½–3 in. long, ovate-lanceolate, cuneate at the base; secondary broad, almost subpalmate below, irregularly pinnatifid. Ultimate segments linear, often elongated and decurved, about $\frac{1}{10}$ in. broad, obtuse, flat, quite entire. Sori numerous, terminating the segments, sunk in the frond at the base. Indusium orbicular, cuneate at the base, 2-valved more than half-way down; valves convex, rounded at the tip, entire; clusters of sporangia often exserted.—*Hook. and Grev. Ic. Fil.* (1829) t. 60; *A. Cunn. Precur.* (1836) n. 233; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 104; *Hook. f. Fl. Nov. Zel.* ii (1855) 13; *Handb. N.Z. Fl.* (1864) 354; *Hook. and Bak. Syn. Fil.* (1873) 62; *Thoms. N.Z. Ferns* (1882) 40; *Field N.Z. Ferns* (1890) 59, t. 16, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 934. Trichomanes dilatatum *Forst. f. Prodr.* (1786) n. 467.

North and South Islands, Stewart Island, Chatham Islands: Abundant in damp woods throughout. Auckland Islands: *Sir J. D. Hooker* (Handbook). Sea-level to 3000 ft.

Also in several of the Polynesian islands and in Java. One of the most handsome species of the genus.

8. **H. demissum** *Swartz Syn. Fil.* (1806) 147.—Terrestrial or epiphytic, forming large patches. Rhizome long, wiry, creeping. Fronds erect or decurved, membranous, bright pale-green, 4–16 in. long including the stipes, 2–5 in. broad, ovate-deltoid or ovate-lanceolate, acuminate, 3–4-pinnatifid. Stipes 2–6 in. long, terete, smooth and glabrous, wiry, not winged above or very obscurely so; rhachis obviously winged in the upper part, but the wing much narrowed and sometimes obsolete below. Primary pinnae spreading or ascending, rhombic-lanceolate or rhombic-triangular; secondary short, broad, again 1–2-pinnatifid. Ultimate segments $\frac{1}{10}$–$\frac{1}{5}$ in. long, $\frac{1}{20}$ in. broad, linear, obtuse, flat, quite entire. Sori small, very numerous at the tips of the segments, not confined to the lateral ones, not sunk in the frond. Indusium ovate, obtuse or subacute, 2-valved to the base; valves entire or lobed.—*A. Rich. Fl. Nouv. Zel.* (1832) 92; *A. Cunn. Precur.* (1836) n. 245; *Raoul Choix* (1846) 39; *Hook. Sp. Fil.* i (1846) 109; *Hook. f. Fl. Nov. Zel.* ii (1855) 14; *Handb. N.Z. Fl.* (1864) 354; *Hook. and Bak. Syn. Fil.* (1873) 61; *Thoms. N.Z. Ferns* (1882) 41; *Field N.Z. Ferns* (1890) 58, t. 18, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 934. H. erecto-alatum *Col. in Trans. N.Z. Inst.* xi (1879) 431. H. megalocarpum *Col. in Trans. N.Z. Inst.* xv (1883) 318. H. polychilum *Col. in Trans. N.Z. Inst.* xxiv (1892) 395. Trichomanes demissum *Forst. f. Prodr.* (1786) n. 468.

Kermadec Islands, North and South Islands, Chatham Islands, Stewart Island, Auckland Islands: Abundant in woods throughout. Sea-level to 3000 ft.

Also found in Polynesia, Java, and the Philippine Islands. The veinlets often fork towards the tips of the segments, and in profusely fruited specimens there is usually a sorus at the tip of each veinlet. When the fork of the veinlet is very close to the tip of the segment the two sori are often included in a single indusium, the valves of which, however, are more or less cleft at the apex. All gradations can be traced between two indusia placed side by side, and a single indusium containing 2 receptacles. Mr. Colenso's *H. megalocarpum* and *H. polychilum*, named specimens of which appear to me to be identical, are founded mainly on this peculiarity, and show no other differences. His *H. erecto-alatum* was separated on account of the broader crisped wing of the rhachis, but the type specimens prove this character to be a very obscure and uncertain one.

9. **H. scabrum** *A. Rich. Fl. Nouv. Zel.* (1832) 90, t. 14, f. 1.—Usually clothing the trunks of trees, rarely terrestrial. Rhizome long, creeping, wiry, more or less bristly with reddish-brown scales. Fronds very variable in size, usually from 6 in. to 20 in. long, but luxuriant specimens sometimes attain 30 in., 2–5 in. broad, ovate-deltoid or ovate-lanceolate or linear-oblong, acuminate, membranous, dark olive-green or olive-brown, erect or pendulous, 3–4-pinnatifid. Stipes 2–6 in. long, not winged, more or less densely clothed (as are the primary and secondary rhachides and costae) with reddish-brown jointed hairs; rhachis winged above, wingless below. Primary pinnae 1–3 in. long, close or rather distant, spreading or erecto-patent, rhomboidal-lanceolate or -oblong, acuminate; secondary deeply pinnatifid or 2-pinnatifid. Ultimate segments linear, obtuse, flat, quite entire. Sori numerous, terminal on the lateral segments on both sides of the pinna. Indusium rather small, orbicular or ovate-orbicular, 2-valved to the base; valves usually toothed.—*A. Cunn. Precur.* (1836) n. 235; *Raoul Choix* (1846) 39; *Hook. Sp. Fil.* i (1846) 110; *Hook. f. Fl.*

Nov. Zel. ii (1855) 15; *Handb. N.Z. Fl.* (1864) 355; *Hook. and Bak. Syn. Fil.* (1873) 61; *Thoms. N.Z. Ferns* (1882) 42; *Field N.Z. Ferns* (1890) 62, t. 17, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 935. Sphaerocionum glanduliferum *Presl Epim.* (1849) 23, t. 12.

North and South Islands, Chatham Islands: Moist forests from Hokianga southwards, not uncommon. Sea-level to 3000 ft.

A distinct and beautiful species, easily recognized by the reddish hairs on the stipes, rhachis, and costae, and by the dark colour of the frond. It is confined to New Zealand.

10. **H. flabellatum** *Lab. Pl. Nov. Holl.* ii (1806) 101, t. 250.—Densely matted, usually clothing the trunks of trees. Rhizomes long, wiry, creeping, often much branched and interlaced, more or less clothed with yellow-brown woolly hairs. Fronds very variable in size and shape, usually 3–9 in. long, but sometimes reduced to less than 1 in., at other times attaining a length of 12 in., the smaller specimens generally ovate and erect, the longer ovate-lanceolate to lanceolate or linear-oblong and pendulous, pale shining-green or yellow-green, membranous, glabrous or sparingly silky along the rhachis and sometimes on the margins, 2–3-pinnatifid. Stipes slender, terete, wingless, glabrous except a tuft of silky hairs at the base; main rhachis winged towards the top, wingless elsewhere. Primary pinnae often close and overlapping, short, rhomboidal-ovate or flabellate, acuminate; secondary cuneate at the base, deeply pinnatifid. Ultimate segments linear, flat, entire. Sori small, terminal on the segments, usually on the lateral ones, slightly immersed at the base. Indusium orbicular or nearly so, 2-valved to below the middle; valves usually entire.—*Hook. Sp. Fil.* i (1846) 111; *Hook. f. Fl. Nov. Zel.* ii (1855) 15; *Handb. N.Z. Fl.* (1864) 355; *Hook. and Bak. Syn. Fil.* (1873) 61; *Benth. Fl. Austral.* vii (1878) 705; *Thoms. N.Z. Ferns* (1882) 42; *Field N.Z. Ferns* (1890) t. 19, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 935. H. nitens *R. Br. Prodr.* (1810) 159; *A. Rich. Fl. Nouv. Zel.* (1832) 94; *A. Cunn. Precur.* (1836) 236; *Raoul Choix* (1846) 39.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Not uncommon in woods throughout. Sea-level to 2500 ft.

Also in Tasmania and south-eastern Australia, and reported from Sumatra and the Philippine Islands. Some varieties approach very closely to narrow-fronded forms of *H. demissum*, but in its ordinary state it cannot be easily confounded with any other.

11. **H. rufescens** *T. Kirk in Trans. N.Z. Inst.* xi (1879) 457, t. 19A.—Very delicate, forming mats on the trunks of trees or on the perpendicular faces of shaded rocks. Rhizome very slender, almost filiform, branched, creeping, sparingly clothed with soft spreading hairs. Stipes much longer than the frond proper, 1–2 in., capillary, wingless, clothed when young with long flexuous hairs. Fronds $\frac{1}{2}$–$1\frac{1}{2}$ in. long, $\frac{1}{2}$–$\frac{3}{4}$ in. broad at the base, deltoid, delicately membranous and pellucid, 2-pinnatifid; rhachis winged almost to the base, and with the veins and occasionally the surfaces of the frond more or less covered with long flexuous silky hairs. Pinnae 3–4 pairs, close, overlapping, cuneate-rhomboid or the lowest almost flabellate, deeply pinnatifid or lobed. Segments linear, obtuse, flat, quite entire. Sori terminating the segments, slightly immersed at the base. Indusium ovate-orbicular, 2-valved to the base; valves entire or slightly toothed, often ciliate.—*Bak. in Annals of Bot.* v (1890–91) 192; *Thoms. N.Z. Ferns* (1882) 43; *Field N.Z. Ferns* (1890) 63, t. 15, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 936.

North Island: Summit of Te Aroha Mountain, *Adams! T. F. C.*; Oroua River (Ruahine Range), *H. C. Field!* Mount Egmont Ranges, *T. F. C.* South Island: Nelson—Mount Arthur Plateau, *T. F. C.*; Takaka Valley, *Kingsley*; Mount Rochfort, *Rev. F. J. Spencer!* Westland—Okarito, *A. Hamilton!* Southland—Lake Hauroko, *Crosby Smith.* Stewart Island: Rakiahua, *A. Hamilton, P. Goyen, Dr. Cockayne.* 1000–3500 ft.

Nearest to *H. flabellatum*, some mountain forms of which approach it very closely, but separated by the much longer capillary stipes, shorter, broader, and more delicate fronds, and by the copious hairs. *H. ferrugineum* differs in the larger size, the shape of the frond, and in the stellate tomentum.

12. **H. ciliatum** *Swartz Syn. Fil.* (1806) 147.—Usually epiphytical. Rhizome slender, creeping, 1–2 in. long. Fronds 2–6 in. long, 1–2 in. broad, ovate-oblong, acuminate, thin and membranous, 2-3-pinnatifid, more or less clothed with stalked branched or stellate hairs, which are most abundant on the margins. Stipes 1–2 in. long, winged above and ciliated; rhachis broadly winged throughout and also conspicuously ciliated with stellate hairs. Primary pinnae oblong or rhomboidal, cut down to a broad central portion into numerous secondary divisions, which are simple or forked or irregularly pinnatifid. Ultimate segments linear, flat, obtuse, quite entire. Sori numerous, terminating the segments, more or less immersed. Indusium suborbicular, 2-valved half-way down; valves ciliated.—*Hook. f. Handb. N.Z. Fl.* (1864) 747; *Hook. and Bak. Syn. Fil.* (1873) 63; *Thoms. N.Z. Ferns* (1882) 43; *Field N.Z. Ferns* (1890) 64; *Cheesem. Man. N.Z. Fl.* (1906) 937.

South Island: Nelson—*Travers* (Handbook).

An abundant plant throughout the whole of tropical America, from Cuba and Mexico to Chile; also in tropical Africa, Madagascar, and Mauritius. I have seen no New Zealand specimens, the plant not having been refound since its original discovery by Mr. Travers nearly forty years ago.

13. **H. ferrugineum** *Colla in Mem. Act. Torino*, 39 (1836) 30.—Forming dense mats on the stems of fern-trees and on tree-trunks, or on the perpendicular faces of shaded rocks. Rhizome long, slender, filiform, tomentose with reddish-brown hairs. Fronds 2–10 in. long, $\frac{3}{4}$–2 in. broad, ovate-lanceolate or lanceolate, acute or acuminate, very thin and membranous, yellow-brown or tawny, usually pendulous, 2–3-pinnatifid, everywhere clothed with copious silky stellate hairs. Stipes filiform, not winged; rhachis narrowly winged above, wingless below. Primary pinnae short, erecto-patent, ovate-lanceolate, cuneate at the base; secondary irregularly pinnatifid or forked. Ultimate segments close, linear, obtuse, flat, quite entire. Sori numerous, small, terminal, sunk in the tips of the lateral segments. Indusium orbicular or broader than long, 2-valved almost to the base; valves rounded, copiously ciliated with stellate hairs.—H. subtilissimum *Kunze Anal. Pteridog.* (1837) 49; *Hook. and Bak. Syn. Fil.* (1873) 64; *Field N.Z. Ferns* (1890) 63, t. 15, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 937. H. aeruginosum *Hook. Sp. Fil.* i (1846) 94, *non Carm.*; *Hook. f. Fl. Nov. Zel.* ii (1855) 15; *Handb. N.Z. Fl.* (1864) 355. H. Franklinanum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 183.

North and South Islands, Stewart Island: Damp forests from Kaitaia southwards, not uncommon, except on the east coast of the South Island, where it is rare and local. Sea-level to 2500 ft.

Also on the Island of Juan Fernandez and in Chile, and closely allied to the Tristan d'Acunha *H. aeruginosum* Carm., with which it was united by Sir J. D. Hooker.

14. **H. Malingii** *Metten. Abh. Sachs. Ges. Wiss.* 7 (1864) 489.—Forming small patches on the trunks and branches of trees. Rhizome slender, creeping, sparsely clothed with reddish-brown hairs. Fronds 2–8 in. long, ½–1½ in. broad, narrow-oblong to linear, erect or pendulous, opaque, rigid, reddish-brown or greyish-brown, everywhere most densely covered with stellate hairs mixed with very minute close-set clavate papillae, 2–3-pinnatifid. Stipes 1–3 in. long, very slender, almost filiform, not winged, densely tomentose. Pinnae close or distant, ⅓–⅔ in. long, rarely more, the lower ones ovate-rhomboidal, the upper oblong, deeply pinnatifid; secondary divisions cuneate or flabellate, deeply pinnatifidly cut. Ultimate segments very narrow-linear, obtuse, almost terete and coriaceous from the dense coating of tomentum, which entirely conceals the frond proper. Sori small, terminating the segments. Indusium hidden by the tomentum, orbicular, 2-valved rather more than half-way down; valves denticulate at the apex.—*Hook. and Bak. Syn. Fil.* (1873) 66; *Thoms. N.Z. Ferns* (1882) 44; *Field N.Z. Ferns* (1890) 67, t. 7, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 938; *Ill. N.Z. Fl.* ii (1914) t. 235. Trichomanes Malingii *Hook. Garden Ferns* (1862) t. 64; *Hook. f. Handb. N.Z. Fl.* (1864) 357.

North Island: Summit of Te Aroha Mountain, *Adams! T. F. C.;* Mount Egmont, *Mrs. Jones, T. F. C.;* Waimarino Plains, *T. F. C., E. Phillips Turner!* Ruahine Mountains and base of Ruapehu, *H. C. Field.* South Island: Nelson—Mountains behind Massacre Bay, *Maling;* Takaka, *Kingsley;* Motueka, *Cockayne.* Westland—Mountains near Greymouth, *Enys!* near Kumara, *J. M. Brame!* Franz Josef Glacier, *Cockayne, Haast.* Canterbury—Banks Peninsula, *T. H. Potts!* Otago—Mount Cargill, Pine Hill, *Buchanan! Thomson!* 500–3500 ft.

A most curious and remarkable little plant, confined to New Zealand. The peculiar indumentum of the frond is well worth careful examination. It is usually found on trunks of *Libocedrus Bidwillii;* but Mr. Phillips Turner has noticed it on *Dacrydium intermedium,* and I have seen it on *Nothofagus Menziesii.*

15. **H. Cheesemanii** *Bak. ex Hook. and Bak. Syn. Fil.* edit. 2 (1873) 464.—Minute, forming cushions on the branches of trees, or creeping amongst mosses and hepaticae. Rhizome branched, wide-creeping, smooth and wiry. Fronds very small, ¼–1 in. long, simple or forked or digitately 3–5-fid, quite glabrous, dark-green, texture firm. Stipes very short, filiform ⅛–¼ in. long. Segments about ⅒ in. broad, linear-oblong or ligulate, obtuse, with a single stout dark-coloured costa in each; margins not usually conspicuously thickened, strongly ciliate-dentate; teeth ascending, dark-brown or black, sometimes caducous. Sori 1–3 to a frond, terminating the segments. Indusium slightly sunk in the frond at the base, orbicular-oblong, dark brownish-black, of a more compact texture than the frond, 2-valved nearly to the base; valves smooth, convex, quite entire, recurved in age.—*Ic. Plant.* (1876) t. 1132; *Cheesem. in Trans. N.Z. Inst.* viii (1876) 329; *Thoms. N.Z. Ferns* (1882) 36; *Field N.Z. Ferns* (1890) 65, t. 5, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 938.

Var. **Armstrongii.**—Precisely similar in size and habit, but texture firmer, and margins strongly thickened.—H. Armstrongii *T. Kirk in Trans. N.Z. Inst.* x (1878) *App.* 43, t. 21A; *Bak. Ic. Plant.* t. 1614. H. melanocheilos *Col. in Trans. N.Z. Inst.* xvii (1885) 255. Trichomanes Armstrongii *Bak. ex Hook. and Bak. Syn. Fil.* edit. 2, 465.

North Island: Auckland—Mongonui County, *H. Carse.* Whangaroa, *R. W. Rowson!* Great Barrier Island, *T. Kirk!* Whangarei, Coromandel, Thames, Waitakere, Hunua, *T. F. C.;* Te Aroha Mountain, *J. Adams!* South Island: Nelson—Mokohinui, *T. Kirk!* Canterbury—Upper Waimakariri and Arthur's Pass, *Armstrong! Enys! T. Kirk! T. F. C.* Westland—Hokitika, *T. Kirk;* Kumara, *J. M. Brame!* Okarito, *A. Hamilton!* Stewart Island: Ruggedy Mountains, *T. Kirk.* Sea-level to 3500 ft.

A peculiar little species, usually found among moss on the upper branches of forest trees, or on the perpendicular faces of rocks. I am unable to maintain *H. Armstrongi* as a separate species, for the stout marginal nerve, which is supposed to separate it from *H. Cheesemanii*, is an inconstant character, and fronds may be picked from the same rhizome with or without it. Usually, however, epiphytic specimens want the nerve, and rupestral ones possess it.

16. **H. minimum** *A. Rich. Fl. Nouv. Zel.* (1832) 91, t. 14, f. 2.—Minute, forming matted patches on rocks or on the trunks of trees. Rhizome much branched, filiform, wide-creeping, glabrous or sparingly bristly. Stipes wiry, filiform, naked, $\frac{1}{6}$–$\frac{1}{2}$ in. long. Fronds very small, $\frac{1}{4}$–$\frac{3}{4}$ in. long, broadly oblong-deltoid or ovate, erect or recurved, firm, pale-green when fresh, often reddish-brown when dry, pinnatifid or pinnate at the base. Segments 2–6 pairs, close, spreading, simple or the lower ones forked, linear, obtuse, more or less concave, rigid, quite glabrous; margins spinulose-dentate. Sori never more than one to a frond, terminating the main rhachis, stipitate, quite free. Indusium rather large, obovate-cuneate, narrowed at the base, 2-valved to the middle; valves spinulose on the back; margins rounded, sharply spinulose-dentate. Receptacle stout, often exserted in age.—*A. Cunn. Precur.* (1836) n. 242; *Raoul Choix* (1846) 39; *Hook. f. Fl. Antarct.* i (1844) 103; *Fl. Nov. Zel.* ii (1855) 12; *Handb. N.Z. Fl.* (1864) 353; *Hook. and Bak. Syn. Fil.* (1873) 464; *Thoms. N.Z. Ferns* (1882) 36; *Cheesem. Man. N.Z. Fl.* (1906) 939.

South Island: Nelson—Tasman Bay, *D'Urville.* Westland—Upper Hokitika Valley and Franz Josef Glacier, *Rev. J. Holloway;* coast near Okarito, *A. Hamilton!* Otago—Resolution Island, *Enys!* East Coast, *Buchanan! A. Hamilton!* Stewart Island: Not uncommon, *T. Kirk!* Auckland Islands: Scarce, *Sir J. D. Hooker.*

A much misunderstood species; most collectors confusing it with small forms of *H. Tunbridgense*, from which, however, it is readily distinguished by the uniformly solitary and terminal sori, the indusium of which is spinulose on the back as well as on the margins.

17. **H. Tunbridgense** *Smith Fl. Brit.* (1794) 1141.—Forming broad densely matted moss-like patches on rocks or on the trunks of trees. Rhizome much branched, long, wiry, creeping. Fronds variable in size, $\frac{1}{2}$–3 in. long, $\frac{1}{2}$–1 in. broad, oblong or linear-oblong, pale-green, membranous, pinnate below, pinnatifid above. Stipes $\frac{1}{2}$–$1\frac{1}{2}$ in. long, slender, wiry, naked; rhachis winged above, wingless below, or sometimes the wing is decurrent almost to the lowest pinna. Pinnae spreading, close or rather remote, usually flabellately pinnatifid. Segments 3–12 to a pinna, linear, obtuse, flat, conspicuously spinulose-dentate. Sori terminal on a short lateral segment near the base of the pinnae on their upper margin and hence supra-axillary, rarely more than one to a pinna. Indusium suborbicular, compressed, its base slightly immersed in the segment, deeply 2-valved; valves thin, smooth on the back; margins conspicuously spinulose-dentate.—*A. Rich. Fl. Nouv. Zel.* (1832) 91; *A. Cunn. Precur.* (1836) n. 243; *Raoul Choix* (1846) 39; *Hook. Sp. Fil.* i (1846) 95; *Hook. f. Fl. Nov. Zel.* ii (1855) 11; *Handb. N.Z. Fl.* (1864) 352; *Hook. and Bak. Syn. Fil.* (1873) 67; *Thoms. N.Z. Ferns* (1882) 35; *Field N.Z. Ferns* (1890) 65, t. 14, f. 7; *Cheesem. Man. N.Z. Fl.* (1906) 939. H. pusillum *Col. in Trans. N.Z. Inst.* xii (1880) 365. (?) H. pygmaeum *Col. l.c.* xiii (1881) 376. H. zeelandicum *Van der Bosch Ned. Arch.* (1856) 77.

Var. **cupressiforme** *Hook. f. Fl. Nov. Zel.* ii (1855) 11.—Fronds taller and narrower, more erect, 1–4 in. high. Pinnae distant; segments more rigid, narrower, often

decurved. Sori free, almost stipitate.—H. cupressiforme *Labill. Pl. Nov. Holl.* ii (1806) 102, t. 250. H. revolutum *Col. in Tasm. Journ. Nat. Sci.* (1846) 186.

North and South Islands, Stewart Island, Auckland Islands: Abundant throughout. Sea-level to 3000 ft.

An abundant plant in most temperate and subtropical countries, and everywhere highly variable. Var. *cupressiforme* has much of the habit of the next species, but the valves of the indusium are spinulose-dentate.

18. **H. peltatum** *Desv. Prodr.* (1827) 333.—Forming large patches on the ground among moss or on the roots of trees. Rhizome long, creeping, branched. Fronds 1–4 in. long, linear-oblong, dark-green, rigidly membranous, pinnate below, pinnatifid above. Stipes $\frac{1}{2}$–$1\frac{1}{2}$ in. long, slender, wiry, naked; rhachis winged in the upper portion only. Pinnae narrower and more rigid than in *H. Tunbridgense*, often pinnatifid on the upper side alone. Segments fewer and narrower, frequently decurved, usually involute, margins conspicuously spinulose-dentate. Sori terminal on short lateral segments near the base of the pinnae on their upper margin, exactly as in *H. Tunbridgense*. Indusium obovate-oblong or broadly oblong, turgid, slightly immersed at the base, deeply 2-valved; valves smooth; margins quite entire.—H. unilaterale *Willd. Sp. Plant.* v (1810) 521; *Hook. f. Fl. Nov. Zel.* ii (1855) 11; *Handb. N.Z. Fl.* (1864) 353; *Cheesem. Man. N.Z. Fl.* (1906) 940. H. Wilsoni *Hook. Brit. Fl.* edit. 1 (1830) 446; *Sp. Fil.* i (1846) 95. H. Tunbridgense *var.* Wilsoni *Hook. and Bak. Syn. Fil.* (1873) 67.

North and South Islands, Stewart Island: From Te Aroha Mountain southwards, not common, chiefly in mountain forests. Sea level to 3500 ft.

Very closely allied to *H. Tunbridgense*, and sometimes hardly to be distinguished from it in the absence of fruit, but usually the frond is taller and narrower and more rigid, the pinnae are sparingly divided and decurved, the segments often unilateral, and the indusia narrower and more turgid, with the margins of the valves quite entire. Its geographical range is nearly the same as that of *H. Tunbridgense*, but it is a much less abundant plant.

19. **H. multifidum** *Swartz Syn. Fil.* (1806) 149.—Forming matted patches upon the ground or on the trunks or branches of trees. Rhizome much branched, creeping, wiry. Fronds variable in size, usually 4–8 in. high including the stipes, but sometimes dwarfed to 1 in., and occasionally attaining 12 in., ovate-lanceolate to oblong-ovate or deltoid, acute or acuminate, erect or decurved or even pendulous, dark olive-green to light-green, membranous, 3–4-pinnatifid. Stipes 1–5 in. long, terete, wiry, naked; rhachis narrowly winged above. Primary pinnae close and often overlapping in terrestrial specimens, more remote in those growing on trees, rhomboidal-lanceolate, cut down to a rather broadly winged rhachis into numerous secondary divisions, which are again pinnatifid or 2-pinnatifid. Ultimate segments linear, rigid, obtuse, deeply spinulose-dentate. Sori few, large, mostly in the upper part of the frond, terminating very short lateral segments, often appearing quite axillary, free. Indusium erect or decurved, obovoid, tubular below, 2-valved to the middle; valves entire or denticulate.—*A. Cunn. Precur.* (1836) n. 240; *Raoul Choix* (1846) 39; *Hook. and Grev. Ic. Fil.* (1829) t. 167; *Hook. Sp. Fil.* i (1846) 98; *Hook. f. Fl. Nov. Zel.* ii (1855) 12; *Handb. N.Z. Fl.* (1864) 353; *Hook. and Bak. Syn. Fil.* (1873) 69; *Cheesem. Man. N.Z. Fl.* (1906) 940; *Thoms. N.Z. Ferns* (1882) 37; *Field N.Z. Ferns* (1890) t. 19, f. 8. H. truncatum *Col. in Trans. N.Z. Inst.* xxiii (1891) 390. H. alpinum *Col. l.c.* xxxi (1899) 263. H. oligocarpum *Col. l.c.* xxxi (1899) 264. Trichomanes multifidum *Forst. f. Prodr.* (1786) 85.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands, Antipodes Island: Abundant throughout. Sea-level to 4000 ft.

Varying greatly in size and habit, but always easily recognized by the very peculiar indusium. It is also found in Fiji and others of the Pacific islands.

20. **H. bivalve** *Swartz Syn. Fil.* (1806) 146.—Forming large matted patches on the ground among moss, more rarely epiphytical. Rhizome stout, wiry, creeping; rootlets densely villous. Fronds (including the stipes) usually from 6–9 in. high, 2–4 in. broad, but luxuriant specimens reach 12–14 in., with a breadth of 6 in., broadly ovate or deltoid, acuminate, rather rigid, often decurved, 3–4-pinnatifid. Stipes 2–5 in. long, terete, wiry, glabrous, not winged; rhachis narrowly winged above. Primary pinnae triangular or ovate-lanceolate, acuminate, cut down almost to the rhachis into rhomboidal-lanceolate secondary divisions, which are again pinnatifid or 2-pinnatifid. Ultimate segments narrow-linear, obtuse, deeply spinulose-dentate. Sori usually numerous, terminal on the segments, immersed at the base. Indusium ovate or ovate-orbicular, cuneate below, 2-valved nearly to the base; valves quite entire.—*A. Rich. Fl. Nouv. Zel.* (1832) 93; *A. Cunn. Precur.* (1836) n. 244; *Raoul Choix* (1846) 39; *Hook. Sp. Fil.* i (1846) 98, t. 35D; *Hook. f. Fl. Nov. Zel.* ii (1855) 12; *Handb. N.Z. Fl.* (1864) 353; *Hook. and Bak. Syn. Fil.* (1873) 69; *Thoms. N.Z. Ferns* (1882) 37; *Field N.Z. Ferns* (1890) 67, t. 17, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 941. H. spathulatum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 184. Trichomanes bivalve *Forst. f. Prodr.* (1786) n. 466.

North Island: Hilly forests from the Great Barrier Island (*C. P. Winkelmann !*) and Cape Colville southwards, not common to the north of the East Cape. South Island, Stewart Island, Chatham Islands: Not uncommon throughout. Sea-level to 3000 ft.

Allied to *H. multifidum*, but a larger and less rigid plant, of a paler-green colour, and with smaller indusia immersed in the tips of the segments, not axillary. It is said to be found in New South Wales.

2. **TRICHOMANES** Smith.

Ferns, usually of small size. Rhizome slender or rather stout, often much branched, glabrous or tomentose. Fronds compound or rarely simple and entire, of the same delicately membranous texture as *Hymenophyllum*, often pellucid, usually of a single layer of cells, rarely of 3-6 layers. Ultimate segments linear or narrow-oblong, entire or rarely toothed at the margin, with a stout central costa. Sori marginal, terminal or lateral, more or less immersed in the frond or quite free, always terminating a vein. Indusium tubular or trumpet-shaped, truncate at the mouth or with a narrow spreading lip or border, usually of the same texture as the frond. Receptacle elongated, filiform or columnar, usually exserted beyond the indusium. Sporangia sessile, depressed, surrounded by a broad complete horizontal ring, bursting transversely.

A genus of nearly 200 species, of almost precisely the same geographical range as *Hymenophyllum*, and agreeing with it in habit and in the delicate texture of the frond, but differing in the shape of the indusium, which is cylindrical or urceolate, and either truncate at the mouth or very shallowly 2-lipped. Of the 7 species found in New Zealand, 3 appear to be endemic, 3 occur in the Polynesian islands, one of them extending as far north as Java and Formosa, the remaining one is found in Australia and Tasmania.

* Fronds simple and entire.

Fronds 2–4 in. diam., broadly reniform with a deep sinus .. 1. *T. reniforme.*

** Fronds small, ½–4 in. long, usually pendulous, delicately membranous, pinnately or 2-pinnately divided; divisions comparatively few.

Fronds ¾–1½ in., digitately or flabellately divided, margins ciliated with branched rufous hairs. Indusium obconical, immersed 2. *T. Lyallii.*

Fronds 1–3 in., dull dark-green, irregularly 2-pinnatifid, segments with a single unbranched costa .. .. 3. *T. humile.*

Fronds 1–4 in., pale-green, irregularly 2-pinnatifid, costa of the segments giving off numerous dichotomous veinlets .. .. 4. *T. venosum.*

Fronds 1–4 in., dark-green, 2–3-pinnately divided; rhachis not winged. Segments very narrow-linear, acute; costa not branched .. .. 5. *T. Colensoi.*

*** Fronds larger, 4–9 in. long, rigidly erect, subcoriaceous, 3–4-pinnatifid; divisions numerous.

Fronds lanceolate, pale yellow-green; ultimate segments narrow-linear, obtuse .. .. 6. *T. strictum.*

Fronds ovate-deltoid, dark-green; ultimate segments broad, oblong, incised at the tips .. .. 7. *T. elongatum.*

1. **T. reniforme** *Forst. f. Prodr.* (1786) n. 462.—Creeping over the ground in moist forests, or clothing the trunks of trees and rotten logs. Rhizome stout, hard, rigid, wide-creeping; rootlets woolly. Stipes 2–8 in. long, erect, wiry, glabrous. Fronds 2–4 in. broad, quite entire, broadly reniform with a deep sinus, dark-green and translucent when fresh, brown and almost horny when dry, flat or undulate, glossy, quite glabrous; veins radiating from the base, numerous, close, prominent, repeatedly dichotomous, spurious venules wanting. Sori very numerous, crowded, often encircling the whole of the margin of the frond. Indusium narrow cup-shaped or almost bell-shaped. Receptacle far-exserted, stout, columnar, covered with sporangia.—*A. Rich. Fl. Nouv. Zel.* (1832) 95; *A. Cunn. Precur.* (1836) n. 228; *Raoul Choix* (1846) 48; *Hook. Sp. Fil.* i (1846) 115; *Exotic Ferns* (1827) t. 2; *Hook. and Grev. Ic. Fil.* (1829) t. 31; *Hook. f. Fl. Nov. Zel.* ii (1855) 16; *Handb. N.Z. Fl.* (1864) 356; *Hook. and Bak. Syn. Fil.* (1873) 73; *Thoms. N.Z. Ferns* (1882) 46; *Field N.Z. Ferns* (1890) 68, t. 2, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 943. Cardiomanes reniforme *Presl Hym.* (1843) 12.

North and South Islands, Stewart Island, Chatham Islands: From the North Cape southwards, abundant in damp woods, except on the eastern side of Canterbury, Otago, and Stewart Island, where it is rare and local. Sea-level to 3000 ft. *Kidney-fern; Raurenga.*

A very distinct and beautiful species, quite unlike any other. The frond differs from that of all the other species in having from 4 to 6 layers of cellules. It is confined to New Zealand, its reported occurrence in Australia (Handb. N.Z. Fl. 747) not having been confirmed.

2. **T. Lyallii** *Hook and Bak. Syn. Fil.* (1873) 77.—Small, pendulous, very delicate, clothing the trunks of trees in damp forests. Rhizome branched, creeping, capillary, sparingly clothed with simple or stellate red-brown hairs. Stipes 1–2 in. long, very slender, filiform. Fronds ¾–1½ in. long and broad, deltoid or suborbicular in outline, delicately membranous and diaphanous, digitately or flabellately divided almost to the base. Segments simple or dichotomously branched, linear, obtuse, flat, minutely denticulate; margins ciliated with branched rufous hairs. Sori few or many to a frond, deeply sunk in the tips of the segments. Indusium obconical, the width of the mouth about equalling the depth of the tube;

margins ciliated, not dilated nor bordered. Receptacle included.—*Thoms. N.Z. Ferns* (1882) 45; *Field N.Z. Ferns* (1890) 70, t. 5, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 943; *Ill. N.Z. Fl.* ii (1914) t. 236. Hymenophyllum Lyallii *Hook. f. Fl. Nov. Zel.* ii (1855) 16; *Handb. N.Z. Fl.* (1864) 355.

North and South Islands.—From the Great Barrier Island and Cape Colville southwards, not uncommon in dense moist forests, but rare or absent on the east coast of the South Island, plentiful in Westland and the south-west of Otago. Stewart Island: Mount Anglem, *T. Kirk.* Sea-level to 3000 ft.

Exactly intermediate between *Trichomanes* and *Hymenophyllum*, so far as the structure of the indusium is concerned. It is purely a matter of taste as to which genus it should be referred to.

3. **T. humile** *Forst. f. Prodr.* (1786) n. 464.—Small, pendulous from the faces of rocks or bank-sides. Rhizomes much branched, slender, creeping, intermatted. Stipes short, slender, $\frac{1}{4}$–$\frac{1}{2}$ in. long, winged almost to the base. Fronds 1–3 in. long, $\frac{1}{4}$–$\frac{2}{3}$ in. broad, lanceolate or linear-oblong, quite glabrous, membranous, dark dull-green, irregularly 2-pinnatifid; rhachis winged throughout. Pinnae ascending, forked or again pinnatifid. Ultimate segments linear, flat, obtuse, quite entire, a single costa in each segment, spurious venules wanting. Sori solitary, sunk in the tip of a short lateral segment and on the upper side of a pinna near its base. Indusium tubular or trumpet-shaped; mouth expanded, shortly 2-lipped. Receptacle usually exserted as a long capillary bristle.—*Hook. f. Ic. Fil.* (1829) t. 35; *Hook. Sp. Fil.* i (1846) 123; *Hook. f. Fl. Nov. Zel.* ii (1855) 16; *Handb. N.Z. Fl.* (1864) 356; *Hook. and Bak. Syn. Fil.* (1873) 80; *Thoms. N.Z. Ferns* (1882) 46; *Field N.Z. Ferns* (1890) 70, t. 5, n. 8; *Cheesem. Man. N.Z. Fl.* (1906) 944.

North Island: From the Kermadec Islands (*W. R. B. Oliver!*) southwards, not uncommon in dark woods. South Island: Nelson—Happy Valley, *A. Grant.* Marlborough—Queen Charlotte Sound, *Banks* and *Solander.* Canterbury—Banks Peninsula, *Armstrong.* Sea-level to 2000 ft.

Also in Australia and the Pacific islands, stretching northwards to New Guinea, Java, and Formosa.

4. **T. venosum** *R. Br. Prodr.* (1810) 159.—Pendulous, usually clothing the trunks of tree-ferns. Rhizome long, slender, branched, wide-creeping, densely tomentose. Stipes $\frac{1}{2}$–2 in. long, very slender, capillary, naked. Fronds 1–4 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, linear or lanceolate to oblong, very delicate and membranous, translucent, pale-green, shining, quite glabrous, pinnate; rhachis broadly winged above, naked below. Pinnae 4–8 pairs, very variable in shape and amount of cutting, from linear and undivided to rhomboidal-lanceolate and deeply and irregularly pinnatifid. Segments or lobes flat, obtuse, irregularly sinuate; costa flexuous, with numerous alternate once or twice dichotomous secondary veinlets. Sori generally solitary on each pinna and sunk in a short lobe on the upper margin near the base, but in specimens with broad lower pinnae there may be 2–4 sori placed irregularly on both the upper and lower margins. Indusium tubular; mouth dilated all round, entire or very slightly 2-lipped. Receptacle usually exserted, capillary.—*A. Cunn. Precur.* (1836) n. 229; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 132; *Hook. and Grev. Ic. Fil.* (1829) t. 78; *Hook. f. Fl. Nov. Zel.* ii (1855) 17; *Handb. N.Z. Fl.* (1864) 367; *Hook. and Bak. Syn. Fil.* (1873) 82; *Benth. Fl. Austral.* vii (1878) 702; *Thoms. N.Z. Ferns* (1882) 47; *Field N.Z. Ferns* (1890) 71, t. 14, f. 4;

Cheesem. Man. N.Z. Fl. (1906) 944. T. venustula *Col. in Trans. N.Z. Inst.* xii (1880) 366.

KERMADEC ISLANDS, NORTH AND SOUTH ISLANDS, STEWART ISLAND, CHATHAM ISLANDS: Abundant in moist forests throughout. Sea-level to 2500 ft.

Also in south-eastern Australia and Tasmania. Mr. Colenso's *T. venustulum* is simply a small state with broader lower pinnae sometimes bearing 2–4 sori.

5. **T. Colensoi** *Hook. f. Ic. Plant.* (1854) t. 979.—Pendulous from rocks or from the trunks of trees. Rhizome wide-creeping, branched, capillary, more or less tomentose. Stipes short, slender, naked. Fronds rather distant, 2–5 in. long, ½–1 in. broad, oblong-lanceolate or linear-oblong, acuminate, quite glabrous, membranous, dark-green, 3-pinnatifid; rhachis slender, not winged. Primary pinnae 5–12 pairs, remote, shortly stalked, pinnate at the base, pinnatifid above. Ultimate segments very narrow-linear, acute, quite entire; a central costa only in each segment. Sori solitary on the upper side of a pinna near its base and thus appearing axillary, erect, stipitate, quite free. Indusium tubular, the mouth slightly dilated. Receptacle usually exserted as a long capillary bristle.—*Hook. f. Fl. Nov. Zel.* ii (1855) 17; *Handb. N.Z. Fl.* (1864) 357; *Hook. and Bak. Syn. Fil.* (1873) 85; *Thoms. N.Z. Ferns* (1882) 47; *Field N.Z. Ferns* (1890) 71, t. 22, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 945; *Ill. N.Z. Fl.* ii (1914) t. 236.

NORTH ISLAND: On mossy stones and rocks, not common. Auckland—Ravines at Mamaku, near Rotorua, *J. Stewart!* Lake Waikaremoana, *Colenso!* Taranaki—Mount Egmont Ranges, *J. M. Brame.* Wellington — Tararua Ranges, *Buchanan!* SOUTH ISLAND: Nelson—Near Collingwood, *Travers, Dall!* Takaka Valley and West Wanganui, *Kingsley.* Canterbury—Banks Peninsula, *Armstrong.* Westland — Very abundant on main ranges, *Holloway;* near Okarito, *A. Hamilton!* Otago—Vicinity of Dunedin, *Buchanan! A. Hamilton!* Lake Wanaka, *Haast!* Milford Sound, *Cockayne.* Sea-level to 3,000 ft.

Well distinguished by the finely cut fronds with distant pinnae and very narrow-linear acute segments. Its nearest ally is the South American *T. capillaceum* L.

6. **T. strictum** *Menz. ex Hook. and Grev. Ic. Fil.* (1829) t. 122.—Rhizome very short, erect or inclined, stout, woody, emitting many long wiry rootlets. Fronds numerous, crowded at the top of the rhizome. Stipes 2–4 in. long, stiff, erect, terete, naked or narrowly margined above, furnished with a tuft of red-brown bristles at the base. Fronds 3–6 in. long, 1½–2½ in. broad, lanceolate or linear-oblong, acuminate, rigidly erect, yellowish-green, 3–4-pinnatifid; rhachis narrowly winged throughout or the wing evanescent in the lower part. Primary pinnae close-set, lanceolate, ascending or spreading, the lower sometimes reduced in size; secondary pinnatifid. Ultimate segments narrow-linear, flat, entire, glabrous; texture firm; costa stout, unbranched. Sori usually not very numerous, terminating short segments near the base of the upper margin of the secondary pinnae. Indusium quite free, erect, funnel-shaped, mouth dilated all round. Receptacle exserted, capillary.—*A. Rich. Fl. Nouv. Zel.* (1832) 95; *Hook. Sp. Fil.* i (1846) 136; *Hook. f. Fl. Nov. Zel.* ii (1855) 17; *Handb. N.Z. Fl.* (1864) 356; *Hook. and Bak. Syn. Fil.* (1873) 466; *Thoms. N.Z. Ferns* (1882) 47; *Cheesem. Man. N.Z. Fl.* (1906) 945. T. leptophyllum *A. Cunn. Precur.* (1836) n. 232; *Raoul Choix* (1846) 38. T. Cunninghamii *Van der Bosch.* T. rigidum *var.* strictum *Field N.Z. Ferns* (1890) 72, t. 28, f. 3.

NORTH ISLAND: Damp forests from Kaitaia southwards to Wellington, but far from common; summit of Little Barrier Island, *T. F. C.* SOUTH ISLAND: Nelson—

Massacre Bay, *Lyall, Travers;* Takaka and West Wanganui, *Kingsley.* Westland—Kumara, *J. M. Brame!* Okarito, *A. Hamilton!* Otago—Dusky Sound, *Hector* and *Buchanan, Holloway.* Stewart Island: *Cockayne;* Ulva, rare, *Kirk.* Sea-level to 3000 ft.

Confined to New Zealand, but very closely allied to the widely spread *T. rigidum* Swartz.

7. **T. elongatum** *A. Cunn. Precur.* (1836) n. 231.—Rhizome short, stout, erect or inclined, clothed with the bases of the old stipites; rootlets many, rigid and wiry. Fronds 4–8 at the top of the rhizome. Stipes 3–9 in. long, stout, rigid, terete, rough below and furnished at the very base with a tuft of linear bristles, not winged above. Fronds 3–8 in. long, 1½–3 in. broad, ovate-deltoid, acuminate, rigid, dark olive-green, often coated on the upper surface with mosses and hepaticae, 2–3-pinnatifid; main rhachis scarcely winged except at the very top. Primary pinnae close, rhomboidal-lanceolate, pinnate at the base, pinnatifid above; secondary imbricating, oblong-cuneate, deeply incised or pinnatifid. Ultimate segments or lobes rather broad, usually incised at the tips, the teeth acute; veins stout, branching, one to each tooth. Sori numerous, in the axils of the lobes of the secondary pinnae. Indusium narrow funnel-shaped, quite free; mouth scarcely dilated, entire or very slightly 2-lipped. Receptacle stout, rigid, exserted.—*Raoul Choix* (1846) 48; *Hook. Ic. Plant.* viii (1854) t. 701; *Sp. Fil.* i (1846) 134; *Hook. f. Fl. Nov. Zel.* ii (1855) 17; *Handb. N.Z. Fl.* (1864) 356; *Cheesem. Man. N.Z. Fl.* (1906) 946. T. rigidum *var.* elongatum *Hook. and Bak. Syn. Fil.* (1873) 86; *Thoms. N.Z. Ferns* (1882) 48; *Field N.Z. Ferns* (1890) 73, t. 16, f. 2. T. polyodon *Col. in Trans. N.Z. Inst.* xxviii (1896) 618.

North Island: Dark woods, abundant to the north of the East Cape, from thence rare and local southwards to Cook Strait. South Island: Nelson—Collingwood, *D. Grant;* Takaka and West Wanganui, *Kingsley;* Giles Creek and Buller Valley, *W. Townson!* Marlborough—Queen Charlotte Sound, *Banks* and *Solander.* Canterbury—Banks Peninsula, *Armstrong.* Sea-level to 2500 ft.

Closely allied to the widely distributed *T. rigidum* Swartz, and considered to be a variety of it by Mr. Baker and other pteridologists. But the frond is broader and more deltoid, the rhizome is not creeping, and the stipes and rhachis quite wingless; the pinnae are more imbricate and less divided, and the segments are broader and shorter. It is also found in the New Hebrides and New Caledonia.

3. **LOXSOMA** R. Br.

Rhizome stout, woody, creeping, paleaceous. Fronds erect, coriaceous, opaque, quite glabrous, 3–4-pinnate; stipes long. Veins free, not anastomosing. Sori marginal, in a sinus of the teeth or lobes of the frond, terminating a vein. Indusium cup-shaped or almost urceolate, coriaceous; mouth truncate, entire. Receptacle long, columnar, exserted. Sporangia numerous, mixed with jointed hairs, obovoid or pyriform, girt by a complete oblique ring, bursting vertically.

A genus of a single species, endemic in the northern portion of the Dominion.

1. **L. Cunninghamii** *R. Br. ex A. Cunn. Precur.* (1836) n. 215, t. 31, 32.—Rhizome long, stout, tortuous, densely clothed with linear red-brown hairs. Stipes 1–2 ft. high, erect, pale-brown, glabrous, smooth and polished. Fronds 9–24 in. long, 6–12 in. broad, broadly triangular, coriaceous, dark-green above, glaucous-white or pale-green beneath; rhachis polished, channelled. Primary pinnae rather distant, ascending, the upper alternate, the

lowermost opposite; secondary ovate-lanceolate or lanceolate, pinnate below, pinnatifid above. Ultimate segments oblong, subacute, toothed or notched. Sori inserted in the notches, the indusium pointing backwards from the frond.—*Raoul Choix* (1846) 48; *Hook. Gen. Fil.* (1842) t. 15; *Sp. Fil.* i (1846) 86; *Garden Ferns* (1862) t. 31; *Hook. f. Fl. Nov. Zel.* ii (1855) 18; *Handb. N.Z. Fl.* (1864) 368; *Hook. and Bak. Syn. Fil.* (1873) 56; *Thoms. N.Z. Ferns* (1882) 33; *Field N.Z. Ferns* (1890) 55, t. 12, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 947. Trichomanes coenopteroides *Harv. ex A. Cunn. Precur.* (1836) n. 215. Davallia dealbata *A. Cunn. Precur. l.c.*

North Island: Auckland—In woods from Mangonui and Kaitaia southwards to Te Aroha, not common. Most often seen in the heart of the Cape Colville Peninsula. Sea-level to 1200 ft.

A very remarkable fern, with the habit of a coriaceous *Davallia* or *Dicksonia*, and the sorus of a *Trichomanes*. But the sporangia differ widely from those of *Trichomanes* in having an oblique ring, and the dehiscence is vertical, like that of *Gleichenia* and *Schizaea*. It has generally been placed in the tribe *Hymenophyllaceae*, but the investigations of Professor Bower (Phil. Trans. cxcii, 47 to 52) seem to prove that Presl and Bommer were right in regarding it as constituting a distinct tribe, having affinities with *Gleichenia* and *Schizaea* on the one hand, and on the other with the *Hymenophyllaceae* and *Dennstaedia*.

4. **DICKSONIA** L'Herit.

Usually tree-ferns, but in some species the caudex is short or absent. Fronds large 2–3-pinnate. Stipes smooth or muricate. Veins pinnately forked, veinlets always free. Sori near the margin of the frond, globose, placed on the apex of a veinlet; receptacle more or less elevated. Indusium distinctly 2-valved, the upper valve continuous with the margin of the frond and usually similar to it in texture, consisting of an incurved or concave lobule; lower valve membranous or coriaceous. Sporangia numerous, sessile or nearly so, bursting transversely; ring oblique, complete.

Excluding the sections *Cibotium* and *Patania* (*Dennstaedtia* Bernh.), which seem to be more appropriately kept separate, the genus contains about 17 species, widely dispersed through the tropical and subtropical regions of both hemispheres. The 3 New Zealand species are endemic, but one of them differs but slightly from the Australian *D. antarctica* Labill.

Trunk 6–20 ft., slender, black. Stipes blackish-brown, tubercled. Sori 6–12 on each segment	1. *D. squarrosa.*
Trunk 6–20 ft., very stout, brown. Stipes short, pale-brown, smooth. Sori 3–6 to each segment	2. *D. fibrosa.*
Trunk wanting or very short. Stipes long, smooth, pale. Sori 6–12 to each segment	3. *D. lanata.*

1. **D. squarrosa** *Swartz Syn. Fil.* (1806) 136.—Trunk 6–20 ft. high, slender, black or dark-brown, clothed above with the persistent bases of the old stipites. Fronds 4–8 ft. long, rarely more, 2–3½ ft. broad, oblong-lanceolate, 2–3-pinnate, rigid and coriaceous. Stipes slender, dark-brown or black at the base, paler above, when young clothed with long brownish-black hairs or setae, almost glabrous when old, sides and under-surface rough with numerous small tubercles; rhachis and costae clothed with deciduous reddish-brown wool above, rough with minute tubercles beneath. Primary pinnae 10–20 in. long, 3–5 in. broad, oblong-lanceolate, acuminate; secondary 1½–3 in. long, ¼–½ in. broad, deeply pinnatifid. Barren segments ovate or oblong, rigid, sharply toothed, the teeth almost pungent; fertile smaller and much contracted, pinnatifid. Sori copious, covering the whole

under-surface of the frond, 5–12 on each segment or 1 to each lobule. Indusium rather large, both valves concave.—*A. Cunn. Precur.* (1836) n. 216; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 68; *Hook. f. Fl. Nov. Zel.* ii (1855) 9; *Handb. N.Z. Fl.* (1864) 361; *Hook. and Bak. Syn. Fil.* (1873) 51; *Thoms. N.Z. Ferns* (1882) 31; *Field N.Z. Ferns* (1890) 50, t. 10, f. 6, *and* t. 25, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 953. D. gracilis *Col. in Trans. N.Z. Inst.* xv (1883) p. 306. Trichomanes squarrosum *Forst. f. Prodr.* (1786) n. 476.

North and South Islands, Stewart Island, Chatham Islands.—Abundant in woods throughout. Sea-level to 2500 ft. *Weki* or *Wheki.*

Easily recognized by the slender blackish trunk, harsh and coriaceous fronds, dark-coloured stipes rough with small tubercles beneath, and rather large copious sori. The trunk is occasionally branched and sometimes produces numerous adventitious buds along its whole length, crowned with miniature fronds. A form possessing this peculiarity, and with the fronds rather narrower and more finely cut than usual, was described by Mr. Colenso as a distinct species under the name of *D. gracilis.* I cannot separate it even as a variety.

2. **D. fibrosa** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 179.—Trunk 8–20 ft. high, stout, columnar, everywhere thickly coated with matted fibrous aerial rootlets, giving it a diameter when mature of from 1–2 ft., clothed towards the top with the old pendent withered fronds. Fronds numerous, 30 or more, spreading, 4–8 ft. long, 1½–2 ft. broad, lanceolate, 2–3-pinnate, coriaceous but not so much so as in *D. squarrosa.* Stipes very short, clothed at the base with dense bright red-brown fibrillose scales; rhachis and costae pale-brown, smooth, densely pilose on both surfaces with soft brownish hairs. Primary pinnae 4–10 in. long, 1½–2½ in. broad, lanceolate, acuminate or almost caudate; secondary ¾–1½ in. long, ¼–½ in. broad, linear or linear-oblong, pinnatifid or pinnate at the very base. Segments rather close, falcate, acute; the barren ones larger and broader, almost flat, acutely coarsely toothed; fertile smaller, contracted, concave, obtusely pinnatifid. Sori very numerous, covering the whole under-surface of the frond, small, 3–6 to each segment or 1 to each lobule.—*Hook. Sp. Fil.* i (1846) 68, t. 23B; *Hook. and Bak. Syn. Fil.* (1873) 461; *Field N.Z. Ferns* (1890) 51, t. 10, f. 5, *and* t. 25, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 953. D. antarctica *Hook. f. Fl. Nov. Zel.* ii (1855) 10; *Handb. N.Z. Fl.* (1864) 351; *Thoms. N.Z. Ferns* (1882) 31 (*not of Labill.*). D. intermedia *Col. ex Hook. and Bak. Syn. Fil.* (1873) 461. D. Sparrmanniana *Col. in Trans. N.Z. Inst.* xii (1880) 364. D. microcarpa *Col. in Trans. N.Z. Inst.* xx (1888) 214.

North and South Islands: From Tauranga and the Middle Waikato southwards, abundant in forests. Chatham Islands: *Miss Seddon!* Sea-level to 2500 ft. *Weki-ponga; Kuripaka.*

Very close indeed to the Australian *D. antarctica,* but a much smaller plant, with densely pilose rhachides and costae, and smaller sori. Mr. Colenso's *D. Sparrmanniana* is a short-trunked form with rather broader fertile segments; and his *D. microcarpa* has smaller and more finely cut fronds, with smaller sori; but they both merge gradually into the ordinary form. The Maoris formerly sliced the fibrous outside of the trunk into slabs, and used them in the construction of their food-houses, for the purpose of excluding rats.

3. **D. lanata** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 181.—Caudex usually long, prostrate and rooting, as thick as the wrist; more rarely short, stout, erect, and attaining a height of 3–6 ft. Fronds few, 3–6 ft. long, 1–3 ft. broad, ovate or ovate-lanceolate, acuminate, 2–3-

pinnate, thick and coriaceous but hardly rigid, yellowish-green above, paler beneath. Stipes from half as long to as long as the frond, pale, smooth, clothed at the base with long purplish-brown or yellowish-brown fibrillose scales, when young more or less covered (together with the rhachis and costae) with soft woolly deciduous hairs, almost glabrous when mature. Primary pinnae 6–12 in. long, 2–4 in. broad, oblong-lanceolate, acuminate; secondary 1–3 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, pinnate or pinnatifid. Segments or pinnules rather closely set, slightly falcate; barren oblong or ovate, obtusely or acutely toothed or lobulate; fertile smaller and narrower, deeply pinnatifid. Sori copious, 6–12 to a segment or 1 to each lobule.—*Hook. Sp. Fil.* i (1846) 59, t. 23c; *Hook. f. Fl. Nov. Zel.* ii (1855) 10; *Handb. N.Z. Fl.* (1864) 351; *Hook. and Bak. Syn. Fil.* (1873) 461; *Thoms. N.Z. Ferns* (1882) 31; *Field N.Z. Ferns* (1890) 53, t. 11, f. 1A, 1B, 1C; *Cheesem. Man. N.Z. Fl.* (1906) 954. D. laevis *Heward ex Sp. Fil.* i (1846) 69.

At Whangarei, Bay of Islands, and other northern localities this usually produces a short stout trunk, but to the south of Auckland it is invariably stemless. Possibly there may be two distinct varieties with a different geographical range, but so far I have failed to find distinctive characters to separate them.

North Island: Hilly forests from Mangonui to Cook Strait, not common. South Island: Nelson—Massacre Bay, *Travers;* Pakawau, *Kingsley!* Westland—Okarito, *A. Hamilton!* Franz Josef Glacier, *Cockayne!* Canterbury—Banks Peninsula, *Armstrong.* Sea-level to 2000 ft.

5. **CYATHEA** Smith.

Tree-ferns, the New Zealand species with a trunk or caudex varying from 10–50 ft. or even more. Fronds very large, usually 2–3-pinnate, very rarely (in species not found in New Zealand) pinnate or undivided. Stipes often muricate or aculeate. Sori dorsal, globose, situated upon a vein or at the fork of a vein; receptacle elevated, globose or elongated. Indusium globose, at first covering the whole sorus, but soon bursting at the summit, often in an irregular manner, usually persistent as a cup surrounding the base of the sorus, its margin entire or laciniate. Sporangia numerous, sessile or nearly so, often mixed with jointed hairs, bursting transversely; ring somewhat oblique, usually complete.

A large and beautiful genus of over 150 species, most plentiful in damp tropical or subtropical regions, unknown in the North Temperate Zone. It attains its southern limit in New Zealand. Of the 4 species found therein, 2 appear to be endemic; the remaining 2 extend to Australia or the Pacific islands.

* Under-surface of frond white.

Trunk 10–30 ft. Fronds 6–12 ft.; stipes and rhachis clothed with yellowish-brown deciduous tomentum .. .. .. 1. *C. dealbata.*

** Under-surface of frond green.

Trunk 20–50 ft. Fronds 8–20 ft., coriaceous; stipes and rhachis conspicuously muricate beneath. Fertile segments lobulate or pinnatifid .. .. 2. *C. medullaris.*

Trunk slender, 20–50 ft. Fronds 8–20 ft., submembranous; stipes and rhachis only slightly asperous. Divisions of frond with attenuated points .. .. 3. *C. Kermadecensis.*

Trunk stout, 8–12 ft. Fronds 8–15 ft.; stipes and rhachis with hard tubercles. Divisions of frond not drawn out into attenuated points .. .. 4. *C. Milnei.*

Trunk 8–20 ft. Fronds 6–10 ft., almost membranous; stipes and rhachis slightly asperous, clothed with strigose hairs above. Fertile segments lobulate or pinnatifid .. .. .. 5. *C. Cunninghamii.*

1. **C. dealbata** *Swartz Syn. Fil.* (1806) 140.—Trunk 10–30 ft. high, seldom more, 9–18 in. diam. at the base, clothed above the middle with the short light-brown bases of the old stipites. Fronds numerous, horizontally spreading, 6–12 ft. long, 2–4 ft. broad, 2–3-pinnate, subcoriaceous, green or yellow-green above, pure-white beneath from a coating of deciduous powder. Stipes rather slender, slightly asperous, clothed at the base with shining dark-brown linear scales, elsewhere (together with the rhachis and costae) more or less covered with yellow-brown deciduous tomentum, becoming almost glabrous when old. Primary pinnae 1–1½ ft. long, oblong, acuminate; secondary, 2–4 in., linear-lanceolate, acuminate or almost caudate, deeply pinnatifid or pinnate towards the base. Segments or pinnules ¼–½ in. long, linear-oblong, acute or subacute, more or less falcate, serrate. Sori small, globose, copious, but often confined to the lower half of the segments. Indusium small, membranous, only covering the sorus in a very early stage, persistent at the base as a shallow cup.—*A. Rich. Fl. Nouv. Zel.* (1832) 77, t. 10. *A. Cunn. Precur.* (1836) n. 226; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 27; *Hook. f. Fl. Nov. Zel.* ii (1855) 7; *Handb. N.Z. Fl.* (1864) 349; *Hook. and Bak. Syn. Fil.* (1873) 26; *Thoms. N.Z. Ferns* (1882) 28; *Field N.Z. Ferns* (1890) 45; *Cheesem. Man. N.Z. Fl.* (1906) 948. (?) Hemitelia falcifolia *Col. Trans. N.Z. Inst.* xxiv (1892) 394. Polypodium dealbatum *Forst. f. Prodr.* (1786) n. 454.

North and South Islands, Chatham Islands: Abundant in woods from the North Cape to Foveaux Strait. Sea-level to 2500 ft *Ponga; Silver Tree-fern.*

Perhaps the most generally distributed of the New Zealand tree-ferns. It can usually be identified at a glance by the milk-white under-surface of the fronds, although individual specimens are occasionally seen in which the under-surface is obscurely glaucous or even quite green. Very young plants are always green beneath; the white first appearing in irregular patches, giving the under-surface a curious piebald appearance. Outside New Zealand it occurs in Lord Howe Island, and a barren plant collected at Penang is assumed to be the same.

2. **C. medullaris** *Swartz Syn. Fil.* (1806) 140.—Trunk 20–50 ft. high or even more, in old plants furnished at the base with a hard and thick conical buttress formed of densely compacted aerial rootlets, sometimes extending for several feet up the trunk, and 1–2½ ft. diam. at the foot; trunk proper rather slender for its height, black, marked with the hexagonal scars of the old stipites, and at the very top rough with the remains of the stipites. Fronds numerous, 20–30, curving, 8–20 ft. long, 3–5 ft. broad, 2–3-pinnate, coriaceous, dark-green above, paler beneath. Stipes stout, clothed at the base with copious black linear scales, and together with the rhachis more or less covered with scattered tubercles. Primary pinnae 1½–3 ft. long, oblong-lanceolate, acuminate; secondary 4–6 in. long, ¾–1½ in. broad, linear-lanceolate to linear-oblong, acuminate, pinnate below, pinnatifid above, costae more or less clothed with tawny silky hairs or glabrous. Pinnules or segments about ½ in. long, $\frac{1}{10}$–⅛ in. broad, linear or linear-oblong, obtuse, falcate; the fertile ones deeply crenate-serrate or lobulate, sometimes pinnatifid; the barren ones broader, crenate-serrate or almost entire; costules usually with pale ciliated scales beneath. Sori very numerous, one to each lobe of the pinnule. Indusium brown, membranous, splitting into 2–4 irregular lobes.—*A. Rich. Fl. Nouv. Zel.* (1832) 78; *A. Cunn. Precur.* (1836) n. 227; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 26; *Hook. f. Fl. Nov. Zel.* ii (1855) 7; *Handb. N.Z. Fl.* (1864) 349; *Hook. and Bak. Syn. Fil.* (1873) 25; *Thoms. N.Z. Ferns* (1882) 28; *Field N.Z. Ferns* (1890) 42, t. 9, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 948.

C. polyneuron *Col. in Trans. N.Z. Inst.* xi (1879) 429. Polypodium medullare *Forst f. Prodr.* (1786) n. 452; *Pl. Escul.* (1786) 74.

North and South Islands, Stewart Island, Chatham Islands: From the Three Kings Islands and the North Cape southwards, abundant, except in the east of Canterbury, Otago, and Stewart Island. Sea-level to 2000 ft. *Korau; Mamaku; Black Tree-fern.*

Apparently the same species occurs in south-east Australia, Tasmania, and in several of the Pacific islands. Colenso's *C. polyneuron*, separated by him chiefly on account of the more numerous veinlets, hardly seems to be entitled to the rank of a variety. The mucilaginous pith of the trunk and lower part of the stipes was formerly baked and eaten by the Maoris, and was considered to be an excellent article of food.

3. **C. Kermadecensis** *Oliver in Trans. N.Z. Inst.* xlii (1910) 158, t. 22. —Trunk tall, slender, 20–50 ft. high or more, furnished at the base with a conical buttress of densely compacted aerial rootlets. Fronds numerous, 8–20 ft. long, 3–4 ft. broad, 2–3-pinnate, subcoriaceous or almost membranous, dull-green above, paler beneath. Stipes slender, clothed at the base with copious linear brown scales, and with the rhachides and costae deeply grooved above. Primary pinnae 15–25 in. long, oblong-lanceolate, acute or acuminate; secondary 3–5 in. long, ½–1 in. broad, linear-oblong, acuminate, pinnate below, pinnatifid above; costae densely clothed with tawny silky hairs intermixed with linear scales; under-surfaces only slightly asperous. Segments ¼–⅓ in. long, linear or linear-oblong, obtuse or subacute. Sori numerous, moderately large, situated at the base of the lobes near the costules. Indusium membranous, persistent, splitting irregularly. —C. Milnei *Cheesem. Man. N.Z. Fl.* (1906) 949, *in part, not of Hook.*

Kermadec Islands: Sunday Island, abundant from sea-level to the tops of the highest hills, alt. 1700 ft., *T. F. C., W. R. B. Oliver!*

This is a noble species, said to occasionally reach the height of 70 ft. During my hurried visit to Sunday Island in 1887 I confounded it with *C. Milnei*, from which it differs in its much greater height, more slender and cleaner trunk, thinner and less coriaceous fronds which have the under-surface of the stipes and rhachis much more asperous, and in the long attenuated pinnae.

4. **C. Milnei** *Hook. ex Hook. f. Handb. N.Z. Fl.* (1864) 349.—Trunk 8–12 ft. high, short, stout, rough with the persistent bases of the old stipes, and at the top often clothed with the pendent withered fronds. Fronds numerous, horizontally spreading, 8–15 ft. long, 2–3 ft. broad, coriaceous, upper surface firm and shining, dark-green, paler beneath. Stipes stout, clothed at the base with copious linear brown scales, under-parts, together with the rhachis, furnished with closely placed hard tubercles. Primary pinnae 14–20 in. long, oblong-lanceolate, sharply acuminate; secondary pinnae 4–6 in. long, ½–1 in. broad, linear-oblong, drawn out into long acuminate points, pinnate below, pinnatifid above, costae clothed on both surfaces with tawny scales. Segments ¼–⅓ in. long, linear, falcate, acute, more or less serrate. Sori copious, nearer the costules than the margin. Indusium membranous, persistent, splitting irregularly. —*Cheesem. Man. N.Z. Fl.* (1906) 949; *Hook. and Bak. Syn. Fil.* (1873) 26; *Oliver in Trans. N.Z. Inst.* xlii (1910) 157, t. 21.

Kermadec Islands: Sunday Island, not so common as *C. Kermadecensis*, *T. F. C., W. R. B. Oliver!*

5. **C. Cunninghamii** *Hook. f. in Hook. Ic. Plant.* (1854) t. 985.—Trunk 8–20 ft. high, rarely more, often coated at the base with densely compacted aerial rootlets, upper part covered with the pendent withered fronds.

Fronds numerous, 20–30, 6–10 ft. long, 2–4 ft. broad, 2–3-pinnate, subcoriaceous or almost membranous, flaccid, dark-green above, paler beneath. Stipes rather slender, dark-coloured at the very base, and furnished with numerous linear scales, elsewhere pale, and together with the rhachis slightly tubercled, more or less covered, especially on the upper surface, with pale yellowish-brown woolly or strigose tomentum. Primary pinnae 1–2 ft. long, 4–6 in. broad, oblong-lanceolate, acuminate; secondary 2–4 in. long, about ¾ in. broad, linear-oblong, acuminate, deeply pinnatifid above, pinnate below. Segments or pinnules ⅓–½ in. long, linear, obtuse, regularly lobulate or pinnatifid; lobules entire; veins forked. Sori copious, one to each lobe of the pinnule, rather nearer the costa than the margin. Indusium brown, membranous, at first covering the sorus, splitting up very irregularly, sometimes leaving an unequal-sided cup with lacerate edges, at other times a single lobe on one side as in *Hemitelia.*—*Hook. f. Fl. Nov. Zel.* ii (1855) 7; *Handb. N.Z. Fl.* (1864) 350; *Hook. and Bak. Syn. Fil.* (1873) 25; *Thoms. N.Z. Ferns* (1882) 29; *Field N.Z. Ferns* (1890) 44, t. 9, f. 1, 2; *Cheesem. Man. N.Z. Fl.* (1906) 950.

North Island: Auckland—Mongonui County, *H. Carse!* Bay of Islands, *Cunningham, Miss Clarke!* Whangarei, *T. F. C.;* Great Barrier Island, *T. Kirk;* Waitakerei and Hunua, *T. F. C.* Wellington—Hutt Valley, *Ralph, Buchanan.* South Island: Nelson—Bateman's Gully, *D. Grant!* Motupiko, *H. H. Allan!* Westland—Wilberg Range, *Cockayne.* Canterbury—Mount Peal, *H. H. Allan!* Chatham Islands: *H. H. Travers! Miss Seddon!* Sea-level to 1500 ft.

Best distinguished from *C. medullaris*, to which it is closely allied, by the smaller size, more membranous fronds, paler and much less muricate stipes and rhachis, which are more or less clothed with yellowish strigose hairs, and by the smaller segments and sori.

6. **HEMITELIA** R. Br.

Tree-ferns, not distinguishable in habit from *Cyathea.* Fronds large, usually 2–3-pinnate, rarely pinnate. Stipes smooth or asperous or muricate. Veins pinnately forked; veinlets free, or the lower ones more or less anastomosing just above the costa. Sori dorsal, globose, situated upon a vein or veinlet; receptacle elevated, globose or elongated. Indusium never covering the sorus, very variable in size and shape, usually a half cup-shaped or semicircular scale on the lower side of the sorus, sometimes small and indistinct, often deciduous. Sporangia numerous, sessile or nearly so, bursting transversely; ring somewhat oblique, complete.

A tropical or subtropical genus, containing about 50 species, 30 of which are natives of America, the remainder scattered through the warm regions of the Old World. It only differs from *Cyathea* in the small one-sided involucre, and several species might be referred to either genus. The single species found in New Zealand is endemic.

1. **H. Smithii** *Hook. ex Hook. and Bak. Syn. Fil.* (1873) 31.—Trunk 6–25 ft. high, about 9 in. diam., coated with fibrous aerial rootlets below, clothed towards the top with the pendulous withered rhachides of the old fronds. Fronds numerous, horizontally spreading, 5–9 ft. long, bipinnate, lanceolate or oblong-lanceolate, acute but hardly acuminate, thin and membranous, bright fresh-green. Stipes slender, clothed at the base with a dense brush of long shining chestnut-brown subulate-lanceolate scales, slightly asperous beneath; rhachis pale yellow-green, almost glabrous when old, when young clothed with strigillose hairs above, and with lax deciduous scales beneath. Primary pinnae 9–15 in. long, 3–4 in. broad, linear-oblong, acuminate;

costae clothed with strigillose hairs above, paleaceous or glabrous beneath; secondary pinnae 1½–2½ in. long, pinnatifid above, pinnate at the base. Segments linear-oblong, acute, slightly falcate, coarsely serrate. Sori copious, on the fork of the veins. Indusium hemispherical, on the costal side of the sorus, variable in size, sometimes almost wrapping round the sorus at the base.—*Thoms. N.Z. Ferns* (1882) 29; *Field N.Z. Ferns* (1890) 46, t. 9. f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 951. Cyathea Smithii *Hook. f. Fl. Nov. Zel.* ii (1855) 8, t. 72; *Handb. N.Z. Fl.* (1864) 350. C. stellulata *Col. in Trans. N.Z. Inst.* xviii (1886) 222.

Var. **microphylla** *Cheesem.*—Fronds fewer in number, soft, delicately membranous, pale grass-green; rhachis densely strigillose above, paleaceous beneath. Primary pinnae rather narrower and more acuminate. Segments smaller, entire or bluntly crenulate towards the tip.—H. microphylla *Col. in Trans. N.Z. Inst.* xxvii (1895) 399.

North and South Islands, Stewart Island: Abundant in damp hilly forests from Kaitaia (Mongonui County) southwards. Sea-level to 2000 ft. Auckland Islands: Norman Inlet, rare, *W. Joss ex Cockayne!*

A very beautiful species, with the most tender fronds of any New Zealand tree-fern. The trunk is not uncommonly forked or branched above; and Mr. Buchanan (Trans. N.Z. Inst. xix (1887) 217) describes and figures a remarkable specimen which had no less than 16 well-developed branches. *H. Smithii* and *Dicksonia squarrosa* are plentiful through the whole of the lowland districts of Stewart Island, in S. lat. 47° 20′, and the former species has recently been found in the Auckland Islands (S. lat. 50° 40′), the extreme southern limit of arborescent ferns.

7. **ALSOPHILA** R. Br.

Usually tree-ferns, but in some species the trunk is short or absent. Fronds large, 2–3-pinnate, very similar to those of *Cyathea* or *Hemitelia*. Veins of the segments forked or pinnately divided. Sori dorsal, globose, situated upon a vein or at the fork of a vein; receptacle more or less elevated, pilose. Indusium altogether wanting. Sporangia numerous, sessile or nearly so, often mixed with hairs, bursting transversely; ring somewhat oblique, complete.

Species about 175, mostly tropical, nearly half of them from America, the remainder scattered through tropical Asia, Malaya, and the Pacific islands, with a few in Africa. The single New Zealand species is endemic.

1. **A. Colensoi** *Hook. f. Fl. Nov. Zel.* ii, 8, t. 73.—Caudex long, prostrate and rooting, seldom more than 6–8 in. in circumference, rarely erect or ascending at the tip and attaining a height of 3–5 ft. Fronds 2–5 ft. long, ¾–2 ft. broad, 2–3-pinnate, broadly ovate-lanceolate, acute, membranous, yellowish-green or reddish-brown. Stipes short, densely covered at the base with pale subulate scales 1 in. long, upper portion, together with the rhachis and costae, more or less thickly clothed with fulvous or reddish-brown hairs intermixed (especially on the under-surface) with pale tumid scales. Primary pinnae 9–15 in. long, 2–3½ in. broad, oblong-lanceolate, acuminate; secondary 1½–2 in. long, about ½ in. broad, pinnatifid above, pinnate at the base. Segments oblong, obtuse, obtusely serrate; veins simple. Sori copious, situated on the middle of the veins.—*Handb. N.Z. Fl.* (1864) 350; *Hook. and Bak. Syn. Fil.* (1873) 40; *Thoms. N.Z. Ferns* (1882) 30; *Field N.Z. Ferns* (1890) 48, t. 3, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 952.

North Island: Mountains of the interior, from Hikurangi and Mount Egmont southwards. South Island: Not uncommon in hilly and subalpine forests throughout. Stewart Island: Mount Anglem, *T. Kirk!* base of Table Hill and Thomson Range,

Cockayne. Usually between 2000 and 4000 ft., but descends to low levels in the south of Otago.

For some interesting remarks on the mode of growth of this species, see Mr. Field's "New Zealand Ferns," quoted above; also a paper by the same author in the "Journal of Botany" for 1878, p. 365.

8. **CYSTOPTERIS** Bernh.

Small membranous and flaccid ferns. Rhizome very short, creeping. Fronds tufted, 2–3-pinnatifid. Veins pinnate and forked; veinlets free, not anastomosing, terminating a little within the margin. Sori small, globose, dorsal, placed at a distance from the margin on the back of a vein. Indusium ovate-deltoid, membranous, jagged, free at the sides, inserted by a broad base under the sorus, and at first bent over it like a hood; ultimately reflexed. Sporangia numerous, stalked, girt by an incomplete vertical ring, bursting transversely.

A small genus of 8 species, found in cool damp mountainous situations in the temperate regions of both hemispheres. The single New Zealand species has the range of the genus.

1. **C. fragilis** *Bernh. in Schrad. Neu. Journ. Bot.* ii (1806) 27, t. 2, f. 9.—Rhizome short, suberect, often branched near the top, clothed with red-brown lanceolate scales. Stipes 1–4 in. long, slender, fragile, stramineous, slightly scaly at the base. Fronds 3–9 in. long, 1–2 in. broad, oblong-lanceolate or ovate-lanceolate, thin and membranous, pale-green, pinnate or 2-pinnate; rhachis smooth, naked, slightly winged above. Primary pinnae rarely more than 1 in. long and usually much less, remote, spreading, lanceolate to ovate, toothed or pinnatifid or again pinnate; pinules oblong, usually deeply toothed or incised. Sori 3–12 to a pinnule, medial on the veins. Indusium very delicate, at first covering the sorus, but soon reflexed and often disappearing in age.—*Hook. Sp. Fil.* i (1846) 197; *Hook. f. Fl. Tasm.* ii (1860) 136, t. 166; *Handb. N.Z. Fl.* (1864) 358; *Hook. and Bak. Syn. Fil.* (1873) 103; *Benth. Fl. Austral.* vii (1878) 752; *Thoms. N.Z. Ferns* (1882) 50; *Field N.Z. Ferns* (1890) 76, t. 18, f. 5, 5A; *Cheesem. Man. N.Z. Fl.* (1906) 957. C. tasmanica *Hook. Sp. Fil.* i (1846) 199; *Ic. Plant.* t. 959. C. novae-zelandiae *J. B. Armstr. in Trans. N.Z. Inst.* xiii (1881) 360. (?) C. laciniatus *Col. in Trans. N.Z. Inst.* xxi (1899) 265.

North Island: Mount Egmont, *Mrs. Jones, T. F. C.;* Tararua Ranges, *Buchanan;* Wairarapa Valley, *H. C. Field.* South Island: Not uncommon in mountain districts throughout. Usually from 1000 to 4000 ft., but descends almost to sea-level in several localities in the South Island.

Almost universally distributed in the North and South Temperate Zones and on the higher mountains of the tropics, and everywhere extremely variable. The New Zealand plant differs from the type in its slightly smaller size and more tender and delicate habit. It was constituted a separate species by Mr. J. B. Armstrong, and a very similar if not identical plant-form from Tasmania was also separated by Sir W. J. Hooker, but afterwards abandoned. After comparing these with a lengthy series of European and North American specimens of *C. fragilis*, I find that the differences are so uncertain and trifling as to dissipate any idea of maintaining the New Zealand plant as distinct.

9. **POLYSTICHUM** Roth.

Rhizome short or erect or ascending, or long and creeping. Fronds tufted at the top of the rhizome, or more or less distant along it, variable in size and cutting, coriaceous, veins free. Sori globose, dorsal, placed

on the back or at the tip of a vein, or at the junction of two veins. Indusium orbicular, attached by a central stalk, flat or convex, membranous, concealing the sorus when young. Sporangia stalked, bursting transversely, girt by an incomplete vertical ring.

A genus of about 100 species, found in most parts of the world. It is easily recognized by the free veins, stiff and coriaceous habit, and usually sharply toothed segments. Of the 8 species found in New Zealand, 3 are endemic, 2 do not extend further than Victoria or Fiji, 1 is abundant throughout the cooler parts of the South Temperate Zone; the remaining 2 are widely spread through the warmer parts of the Southern Hemisphere.

A. Rhizome short, stout, erect. Fronds tufted at the top of the rhizome.

Fronds 1–3 ft.; narrowed below, 2-pinnate; segments sharply toothed. Stipes shaggy with large dark scales mixed with hairs .. .. 1. *P. vestitum.*
Fronds 12–18 in., 2-pinnate; segments narrower and more distant than in the preceding; texture thinner .. .. 2. *P. sylvaticum.*
Fronds 9–18 in., ovate-deltoid, rigid, not narrowed below; segments sharply toothed. Stipes with narrow black scales .. 3. *P. Richardi.*
Fronds 10–20 in., ovate-oblong, not narrowed below, 2–3-pinnate; segments obtusely toothed. Stipes with large black scales margined with white. Indusium with a large black disc .. 4. *P. oculatum.*
Fronds 4–12 in., oblong-lanceolate, soft and almost flaccid, 2-pinnate. Stipes with large pale membranous scales. Indusium large, very convex .. .. 5. *P. cystostegia.*

B. Rhizome long, creeping. Fronds distant along the rhizome.

Fronds 1–2 ft., ovate-deltoid, finely 2–4-pinnate. Stipes and rhachis densely hispid with rigid linear bristles .. .. 6. *P. hispidum.*
Fronds 1–3 ft., deltoid, 2–3-pinnate; ultimate segments obtusely lobed or toothed .. .. 7. *P. adiantiforme.*
Fronds 1–3 ft., deltoid, 2–3-pinnate; ultimate segments with aristate teeth or lobes .. .. 8. *P. aristatum.*

[I have omitted from the enumeration *P. mohrioides* Presl, the existence of which in the New Zealand area depends entirely on Mr. Kirk's record in Trans. N.Z. Inst. xiv, 386. There are no specimens in his herbarium, and I fear that some mistake was made in the identification.]

1. **P. vestitum** *Presl Tent. Pterid.* (1836) 83.—Rhizome short, stout, erect or ascending, sometimes produced into an erect caudex 1–4 ft. high. Stipes 6–18 in. long, stout, erect, densely clothed with spreading scales; many of the scales large, over 1 in. long, ovate-lanceolate or subulate-lanceolate, long-acuminate, lacerate, straight or curved, glossy, black or dark-brown with a pale margin; others bristle-like or woolly, pale-ferruginous or tawny. Fronds numerous, forming a spreading crown at the top of the caudex, 1–3 ft. long without the stipes, 4–9 in. broad, oblong-lanceolate or linear-oblong, acute or acuminate, narrowed towards the base, rather coriaceous, dark-green, glabrous above when mature, under-surface more or less fibrillose, bipinnate; rhachis usually densely scaly like the stipes, but sometimes the broader scales are wanting. Primary pinnae numerous, close-set, horizontally spreading, 2–5 in. long, ½–1 in. broad, linear-lanceolate or lanceolate, acuminate. Pinnules numerous, close, shortly stipitate, ovate-rhomboidal, unequal-sided, more or less auricled on the upper side near the base, toothed or lobed or pinnatifid, the lobes acute or pungent. Sori 6–8 to a pinnule, in 2 rows nearer the midrib than the margin. Indusium rather small, flat, orbicular.—*Hook. f. Fl. Nov. Zel.* ii (1855) 38; *Homb. et Jacq. Voy. au Pôle Sud* (1853) *Crypt.* t. 4, f. s. P. venustum *Homb. et Jacq. l.c.* t. 5, f. x; *Hook. f. Fl. Antarct.*

Polystichum mohrioides (Bory) Presl.
Kapiti & Auckland Islands.
See Allan Trans: Vol 65 p. 23.

i (1844) 106. Aspidium aculeatum *var.* vestitum *Hook. f. Handb. N.Z. Fl.* (1864) 375; *Hook. Sp. Fil.* iv (1862) 22; *Hook. and Bak. Syn. Fil.* (1873) 252; *Thoms. N.Z. Ferns* (1882) 78; *Field N.Z. Ferns* (1890) 126, t. 8, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 997. Aspidium vestitum *Swartz Syn. Fil.* (1806) 53; *A. Rich. Fl. Nouv. Zel.* (1832) 68; *A. Cunn. Precur.* (1836) n. 218; *Raoul Choix* (1846) 38. A. pulcherrimum *and* A. Waikarense *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 161. A. perelegans *and* A. zerophyllum *Col. in Trans. N.Z. Inst.* xxix (1897) 416, 418.

North and South Islands, Chatham Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island, Macquarie Island: Rather local from Cape Colville to the East Cape, not uncommon in hilly districts from thence to Wellington, abundant to the south of Cook Strait. Sea-level to 3500 ft.

Polystichum vestitum is mainly distinguished from the widespread *P. aculeatum* by the copious dark-coloured scales, which usually clothe not only the stipes but also the rhachis up to its tip. It is also found in Australia, Tasmania, and Fuegia, and varies greatly in the size, shape, and texture of the frond, in the shape of the pinnules, and the extent to which they are toothed or lobed, and in many other respects.

2. **P. sylvaticum** *Diels in Pflanzenf.* Teil i, abt. iv (1902) 192.—Rhizome short, erect or ascending. Stipes 4–8 in. long, slender, more or less densely clothed with ovate-lanceolate chestnut or dark ferruginous scales usually mixed with linear-subulate ones. Fronds not very numerous, 1–2 ft. long, 3–6 in. broad, lanceolate, acuminate, gradually tapering to the base, firm but scarcely coriaceous, 2-pinnate. Primary pinnae rather distant, opposite below, alternate above, lanceolate or linear-lanceolate, acuminate, 2–4 in. long, $\frac{1}{2}$–$\frac{3}{4}$ in. wide. Pinnules numerous, $\frac{1}{3}$–$\frac{1}{2}$ in. long, ovate-lanceolate, unequal-sided at the base, pinnatifid about half-way down into 5–8 acute spinulose lobes. Sori usually as many as the lobes. Indusium not developed.—Polypodium sylvaticum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 163; *Hook. f. Fl. Nov. Zel.* ii (1855) 41, t. 81; *Handb. N.Z. Fl.* (1866) 380; *Hook. Sp. Fil.* iv (1862) 249. Polystichum aculeatum *var.* sylvaticum *Cheesem. Man. N.Z. Fl.* (1906) 998.

North and South Islands: From Coromandel and the Thames goldfields to the south of Otago, but not common. 500–3500 ft.

Although closely allied to *P. vestitum* this appears to me to differ in its smaller size and more slender habit, fewer fronds which have a much thinner texture, more distant pinnae, and in the invariable absence of the indusium.

3. **P. Richardi** *J. Smith Hist. Fil.* (1875) 220.—Rhizome short, thick, densely clothed with linear-subulate dark-brown or blackish scales. Stipes 6–18 in. long, stout, erect, more or less clothed with rigid black subulate deciduous scales mixed with woolly hairs. Fronds few, tufted at the top of the rhizome, 9–18 in. long or more without the stipes, 3–9 in. broad, ovate-deltoid to lanceolate-deltoid, acuminate, not narrowed at the base, rigid and coriaceous, glabrous above, more or less woolly or furfuraceous beneath, pinnate or 2-pinnate; rhachis often scaly and woolly like the stipes, but usually less conspicuously so. Pinnae numerous, usually close and compact, but sometimes a little remote, spreading, $\frac{1}{2}$–4 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, lanceolate or ovate-lanceolate, deeply pinnatifid or again pinnate. Pinnules numerous, close, lanceolate or ovate-lanceolate or ovate-oblong, acute or mucronate or pungent, usually more or less acutely serrate, but sometimes the teeth are obtuse or very obscure. Sori in two rows in each pinnule, about half-way between the midrib and the margin.

Indusium orbicular, flat, with a rather large dark disc and pale margin.—P. aristatum *Hook. f. Fl. Nov. Zel.* ii (1855) 37, t. 78 (*not of Presl*). Aspidium Richardi *Hook. Sp. Fil.* iv (1862) 23, t. 222; *Hook. f. Handb. N.Z. Fl.* (1864) 375; *Hook. and Bak. Syn. Fil.* (1873) 253; *Thoms. N.Z. Ferns* (1882) 79; *Field N.Z. Ferns* (1890) 128, t. 13, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 999. Aspidium acutidentatum *A. Rich. Fl. Nouv. Zel.* (1832) 71.

North and South Islands: From the North Cape to the south of Otago, not uncommon in lowland districts, especially near the sea.

Also in Fiji. A variable plant, especially in the extent to which the pinnae are divided, and in the shape and toothing of the pinnules.

4. **P. oculatum** *J. B. Armstr. in Trans. N.Z. Inst.* xiii (1881) 364.—"Rhizome absent. Fronds 10–20 in. long, coriaceous, ovate-oblong, acuminate, 3-pinnate, pale and clothed with woolly hairs below; stipes stout, straw-coloured, covered with rigid, large, subulate, brown scales margined with white; rhachis with fewer softer scales and lax woolly hairs; primary divisions of the frond 2–4 in. long, narrow ovate-lanceolate, acuminate, stalked, not close together; secondary also lax, ⅔–1 in. long, sessile or stalked; pinnules alternate, sessile, decurrent, ¼ in. long, obtuse or mucronate, obtusely toothed or subpinnatifid. Sori abundant over the whole under-surface, 2–4 on each segment; involucre orbicular, shortly stalked, with a large black disc and narrow reddish margin."—Aspidium oculatum *Hook. Sp. Fil.* iv (1862) 24, t. 228; *Hook. f. Handb. N.Z. Fl.* (1864) 376; *Hook. and Bak. Syn. Fil.* (1873) 253; *Thoms. N.Z. Ferns* (1882) 79; *Field N.Z. Ferns* (1890) 129; *Cheesem. Man. N.Z. Fl.* (1906) 999.

North and South Islands: "Wairarapa Valley, *Colenso;* Akaroa, *Raoul*" (Handbook).

I have not identified this with certainty, and have consequently reproduced the description given in the Handbook. It is probably nothing more that a trivial variety of *P. Richardi* with a rather laxer frond than usual, and smaller and shorter pinnules with more obtuse teeth. Mr. Baker keeps it as a distinct species in the "Synopsis Filicum," but in the "Annals of Botany" (v, 314) he remarks that it is evidently a mere variety of *P. Richardi.*

5. **P. cystostegia** *J. B. Armstr. in Trans. N.Z. Inst.* xiii (1881) 364.—Rhizome short, stout, densely scaly, sometimes branched above. Stipes 2–6 in. high, pale-brown, clothed with copious large pale-brown shining membranous lanceolate scales. Fronds very numerous, tufted at the top of the rhizome, 4–10 in. long without the stipes, 1½–2 in. broad, oblong-lanceolate, acute, pale-green, soft, membranous and almost flaccid, both surfaces clothed with linear scales when young, 2-pinnate; rhachis stout, densely scaly. Pinnae spreading, closely placed above the middle, remote below, ½–1½ in. long, ovate-deltoid, pinnate; rhachises often winged. Pinnules ¼–⅓ in. long, ovate-lanceolate, deeply lobed or pinnatifid; segments obtuse or acute. Sori numerous, large, 2–4 to a pinnule. Indusium orbicular, very convex, almost hemispherical, thin and membranous, pale-coloured.—Aspidium cystostegia *Hook. Sp. Fil.* iv (1862) 26, t. 227; *Hook. f. Handb. N.Z. Fl.* (1864) 376; *Hook. and Bak. Syn. Fil.* (1873) 253; *Thoms. N.Z. Ferns* (1882) 79; *Field N.Z. Ferns* (1890) 128, t. 8, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1000; *Ill. N.Z. Fl.* ii (1914) t. 244.

Kuntz 1945 : 11
Fern Kraute
Farn

NORTH ISLAND : Tongariro, *Dieffenbach ;* Mount Egmont, *Mrs. Jones, T. F. C. ;* Tararua Mountains, *Buchanan.* SOUTH ISLAND : Not uncommon in alpine districts throughout. STEWART ISLAND : Mount Anglem, *Cockayne.* AUCKLAND ISLANDS : *T. Kirk.* 3000–5500 ft.

A very distinct little species, easily recognized by the stout soft stipes and rhachis densely clothed with large pale scales, the narrow frond, and large bladdery indusia. A form with a firmer frond and dark-coloured scales on the stipes is occasionally seen.

6. **P. hispidum** *J. Smith in Journ. Bot.* iv (1841) 195.—Rhizome long, stout, creeping, densely clothed with subulate red-brown scales. Stipes 9–18 in. long, stout, erect, brown, everywhere hispid with long rigid linear spreading bristles with a swollen base. Fronds 9–18 in. long or more, 6–12 in. broad, broadly ovate or triangular, acuminate, brownish-green, coriaceous, 3–4-pinnate ; primary and secondary rhachises bristly like the stipes. Primary pinnae 3–8 in. long, ovate-lanceolate or the lowest deltoid, acuminate, the lowest pinnule larger than the others. Secondary pinnae oblong-lanceolate, again 1- or 2-pinnate. Pinnules $\frac{1}{4}$–$\frac{1}{2}$ in. long, narrow-lanceolate, acute, deeply and acutely toothed or almost pinnatifid, the teeth often pungent. Sori large, copious, one to each of the ultimate segments or lobes. Indusium orbicular with an indistinct sinus, flat, brown.—Aspidium hispidum *Swartz Syn. Fil* (1806) 56 ; *A. Rich. Fl. Nouv. Zel.* (1832) 69 ; *A. Cunn. Precur.* (1836) n. 221 ; *Raoul Choix* (1846) 38. Nephrodium hispidum *Hook. Sp. Fil.* iv (1862) 150 ; *Hook. f. Handb. N.Z. Fl.* (1864) 378 ; *Hook. and Bak. Syn. Fil.* (1873) 286 ; *Benth. Fl. Austral.* vii (1878) 760 ; *Thoms. N.Z. Ferns* (1882) 83 ; *Field N.Z. Ferns* (1890) 132, t. 3, f. 3 ; *Cheesem. Man. N.Z. Fl.* (1906) 1004 ; *Ill. N.Z. Fl.* ii (1914) t. 245.

NORTH AND SOUTH ISLANDS, STEWART ISLAND, CHATHAM ISLANDS : Abundant in forests throughout. Sea-level to 2000 ft.

A very distinct species, at once recognized by the finely divided frond and the numerous stiff spreading bristles on the stipes and rhachis. It is also found in Victoria, where, however, it is rare and local.

7. **P. adiantiforme** *J. Smith Hist. Fil.* (1875) 220.—Rhizome long, stout, creeping, covered with large tawny subulate-lanceolate silky scales. Stipes 1–2 ft. long, stout, erect, more or less densely clothed with deciduous scales. Fronds scattered along the rhizome, 9–18 in. long without the stipes, 6–12 in. broad, ovate-deltoid, acuminate, very coriaceous, rigid, glabrous or the under-surface slightly paleaceous, 3-pinnate ; rhachis deciduously scaly. Primary pinnae erecto-patent, stipitate, lanceolate or lanceolate-deltoid, 2-pinnate ; the lowest pair the largest, 4–8 in. long, 2–3 in. broad, the basal secondary pinna on each side of the frond longer than the others. Ultimate segments oblong, obtuse or subacute, shortly and bluntly lobed or almost entire, not mucronate. Sori copious, in 2 rows near the midrib, often covering the whole under-surface. Indusium large, orbicular, sometimes with a distinct sinus.—Aspidium capense *Willd. Sp. Plant.* v (1810) 267 ; *Hook. and Bak. Syn. Fil.* (1873) 254 ; *Benth. Fl. Austral.* vii (1878) 758 ; *Thoms. N.Z. Ferns* (1882) 80 ; *Field N.Z. Ferns* (1890) 129, t. 6, f. 2 ; *Cheesem. Man. N.Z. Fl.* (1906) 1000. Aspidium coriaceum *Swartz Syn. Fil.* (1806) 57 ; *A. Rich. Fl. Nouv. Zel.* (1832) 71 ; *A. Cunn. Precur.* (1836) n. 223 ; *Raoul Choix* (1846) 38 ; *Hook. Sp. Fil.* iv (1862) 32 ; *Hook. f. Handb. N.Z. Fl.* (1864) 376. Aspidium Cunninghamianum *Col. in Tasm. Jour. Nat. Sci.* ii (1846) 166. Polystichum coriaceum *Schott Gen. Fil.* ad t. 9 (1834) ; *Hook. f. Fl. Nov. Zel.* ii (1855) 37. Polypodium adiantiforme *Forst. f. Prodr.* (1786) n. 449.

North and South Islands, Stewart Island, Chatham Islands: Abundant in forests throughout, often climbing up trees. Sea-level to 2000 ft.

A widely distributed fern, found in temperate Australia, Polynesia, South Africa, Mauritius, and in America stretching from Cuba to Patagonia.

8. **P. aristatum** *Presl Tent. Pterid.* (1836) 83.—Rhizome long, stout, creeping, clothed with linear-subulate ferruginous scales. Stipes 9–18 in. long, stout, densely clothed towards the base with linear fibrillose scales. Fronds scattered, 1–2 ft. long by 9–12 in. broad, ovate-deltoid, acuminate, coriaceous, dark-green and glossy, both surfaces naked, 3-pinnate; rhachis glabrous or sparingly paleaceous. Primary pinnae stipitate, lanceolate, acuminate, pinnate or 2-pinnate; the lowest pair the longest, 6–9 in. long, lanceolate-deltoid, with an elongated basal pinnule. Pinnules obliquely ovate-lanceolate or narrow ovate-rhomboid, irregularly dentate with the teeth ending in bristle-like points. Sori rather small, in 2 rows near the midrib. Indusium smooth, flat, orbicular or rarely slightly reniform.—Polypodium aristatum *Forst. f. Prodr.* (1786) n. 448. Aspidium aristatum *Swartz Syn. Fil.* (1806) 53; *Hook. Sp. Fil.* iv (1862) 27; *Hook. f. Handb. N.Z. Fl.* (1864) 376; *Hook. and Bak. Syn. Fil.* (1873) 255; *Benth. Fl. Austral.* vii (1878) 757; *Thoms. N.Z. Ferns* (1882) 80; *Cheesem. Man. N.Z. Fl.* (1906) 1001.

Kermadec Islands: Sunday Island, abundant, *McGillivray, T. F. C., Oliver!*

A most abundant Polynesian plant, also found in tropical Australia, Malaya, India, China, Japan, and South Africa.

10. **DRYOPTERIS** Adanson.

Rhizome long and creeping, or short and tufted. Fronds crowded at the top of the rhizome or scattered along it, very various in size and form, frequently pinnate with the pinnae pinnatifid, or 2–3-pinnate or even decompound. Veins all free, or the lower veinlets in a lobe united by their tips to those of the adjoining lobes, or (in species not found in New Zealand) copiously anastomosing. Sori subglobose, dorsal, placed on the back or at the tip of a vein. Indusium usually conspicuous, but not infrequently feebly developed or even absent, cordate or reniform, attached by the sinus, membranous, often concealing the sorus when young. Sporangia stalked, surrounded by an incomplete vertical ring, bursting transversely.

The genus *Dryopteris*, which through priority of nomenclature now takes the place of *Nephrodium*, and which has been considerably enlarged by the inclusion of those species of *Polypodium* which only differ from *Nephrodium* in the absence of an indusium, now constitutes one of the largest genera of ferns. Of the 9 species found in New Zealand, 5 are widely distributed, 3 are found in Australia or Polynesia, and 1 is endemic.

Subgenus I. Lastrea. *Veins and veinlets all free. Indusium present.*

Rhizome long, creeping. Fronds 6–12 in. long without the stipes, membranous, glabrous except a few scales on the under-surface of the rhachis and costae .. .. 1. *D. Thelypteris.*

Rhizome long, creeping. Fronds 9–18 in. without the stipes, pale-green, finely pubescent. Stipes pubescent .. .. .. 2. *D. decomposita.*

Rhizome short, tufted. Fronds 6–14 in., dark-green, glabrous except the rhachis and costae. Stipes nearly glabrous .. .. 3. *D. glabella.*

Rhizome short, tufted. Fronds 9–18 in., reddish-brown, both surfaces clothed with short velvety pubescence .. .. .. 4. *D. velutina.*

Rhizome short. Fronds 1–3 ft., ovate or ovate-lanceolate, pale-green, membranous; rhachises and under-surfaces with fine spreading hairs .. .. 5. *D. setigera.*

Subgenus II. PHEGOPTERIS. *Veins all free. Indusium absent.*

Stipes continuous with the rhizome. Fronds large, 2–4-pinnate, glandular-pubescent .. .. 6. *D. punctata.*

Subgenus III. GONIOPTERIS. *Veins pinnate in the lobes, the lower veinlets uniting at the tips with those of the adjoining lobes. Indusium absent.*

Stipes continuous with the rhizome. Fronds large, 2–5 ft., pinnate, membranous, glabrous or nearly so .. .. 7. *D. pennigera.*

Subgenus IV. CYCLOSORUS. *Veins pinnate in the lobes, the lower veinlets uniting at the tips with those of the adjoining lobes. Indusium present.*

Rhizome short. Fronds 1–3 ft., soft and membranous, finely pilose; lower pinnae gradually reduced in size .. .. .. 8. *D. parasitica.*

Rhizome long, creeping. Fronds 6–18 in., rather rigid; lower pinnae not reduced in size .. .. 9. *D. gongylodes.*

1. **D. Thelypteris** *Asa Gray Man. Bot. U.S.A.* ed. 1 (1848) 630; var. **squamulosum** *Schlecht. Fil. Cap.* 23, t. 11.—Rhizome long, slender, creeping, branched. Stipes 4–12 in. long, slender, straw-coloured, darker at the base, smooth, naked or slightly scaly when young. Fronds scattered along the rhizome, 6–12 in. long without the stipes, rarely more, 2–5 in. broad, linear-oblong or lanceolate, acuminate, truncate at the base, pale-green, membranous, glabrous except the costae and rhachis which are sparsely clothed beneath with pale broad convex scales, pinnate. Pinnae opposite or nearly so, 1–2½ in. long, ⅓–½ in. broad, linear-oblong, deeply pinnatifid. Segments ⅙–¼ in. long, oblong, obtuse or subacute, quite entire, broader and flatter in the sterile frond than in the fertile. Veins free, the lower or nearly all forked. Sori numerous, small, in two rows, rather nearer the recurved margin than the midrib. Indusium cordate-reniform, glandular-ciliate.—Nephrodium Thelypteris *Hook. Sp. Fil.* iv (1863) 88. *Hook. f. Handb. N.Z. Fl.* (1864) 377; *Hook. and Bak. Syn. Fil.* (1873) 271; *Thoms. N.Z. Ferns* (1882) 81; *Field N.Z. Ferns* (1890) 130, t. 13, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1002. N. squamulosum *Hook. f. Fl. Nov. Zel.* ii (1855) 39.

NORTH ISLAND: Marshes from the North Cape to the East Cape, Taupo, Wanganui, and Otaki, but often local. Sea-level to 2000 ft.

The typical form of the species is found in Europe, north Asia, the Himalayas, and North America; the var. *squamulosum*, which differs chiefly in the scales on the underside of the rhachis and costae, appears to be confined to New Zealand and South Africa.

2. **D. decomposita** *O. Kuntze Rev. Gen. Pl.* ii (1891) 812.—Rhizome long, slender, creeping, branched, more or less clothed with chaffy scales. Stipes 6–18 in. long, firm, erect, scaly towards the base, villous-pubescent above. Fronds scattered along the rhizome, not tufted, 9–18 in. long without the stipes, often almost as broad, ovate-deltoid or pentangular, acuminate, membranous or subcoriaceous, pale-green, more or less finely villous or pubescent, 2-pinnate above, 3-pinnate below; rhachis and costae slender, villous-pubescent: Primary pinnae 4–9 in. long; the lowest pair much the largest, unequally deltoid with the basal secondary pinna on each side much longer than the rest; upper pinnae gradually smaller, ovate-lanceolate. Secondary pinnae lanceolate, deeply pinnatifid or the lower again pinnate; ultimate segments close, unequal-sided, ovate-rhomboid to lanceolate-rhomboid, acutely toothed or lobed. Sori rather large, distant, nearer the margin than the midrib. Indusium orbicular-reniform.—Nephrodium decompositum *Hook. f. Fl. Nov. Zel.* ii (1855) 39, t. 79; *Handb. N.Z. Fl.* (1864) 378; *Hook. Sp. Fil.* iv (1862) 146; *Hook. and Bak. Syn. Fil.* (1873) 281; *Thoms.*

N.Z. Ferns (1882) 82; *Field N.Z. Ferns* (1890) 131, t. 5, f. 7; *Cheesem. Man. N.Z. Fl.* (1906) 1002. N. pentangularum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 169. Aspidium decompositum *Spreng. Syst.* iv (1827) 109; *Benth. Fl. Austral.* vii (1878) 758.

Kermadec Islands, North and South Islands, Chatham Islands: Not uncommon in lowland districts, usually in rich alluvial soils. Sea-level to 1200 ft.

An abundant Australian plant, ranging from the north of Queensland to Tasmania, also in Norfolk Island.

3. **D. glabella** *C. Christen. Ind. Fil.* (1905) 267.—Rhizome short, stout, tufted, clothed with the bases of the old stipites intermixed with subulate scales. Stipes 4–10 in. long, slender, firm, scaly at the base, glabrous or nearly so above. Fronds tufted at the top of the rhizome, 6–14 in. long or more without the stipes, 4–10 in. broad, ovate-deltoid, acuminate, membranous but firm, dark-green, 2–3-pinnate; surfaces almost glabrous except the rhachis and costae, which are more or less clothed with short reddish pubescence. Primary pinnae 2–5 in. long; the lowest pair the largest, deltoid, not so unequal-sided as in *N. decompositum*, and the basal secondary pinnae not conspicuously longer than the rest; upper pinnae lanceolate, acuminate; secondary rhachises margined throughout. Secondary pinnae obliquely ovate-lanceolate or lanceolate, deeply pinnatifid or the lower again pinnate; ultimate segments ovate or oblong, sharply toothed or lobed. Sori distant, about half-way between the margin and the midrib. Indusium pale, orbicular-reniform.—Nephrodium glabellum *A. Cunn. Precur.* (1836) n. 224; *Raoul Choix* (1846) 38; *T. Kirk in Trans. N.Z. Inst.* x (1878) 398; *Thoms. N.Z. Ferns* (1882) 82; *Field N.Z. Ferns* (1890) 131, t. 6, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1003. N. decompositum *var.* pubescens *Hook. f. Fl. Nov. Zel.* ii (1855) 39. N. decompositum *var.* microphyllum *Hook. Sp. Fil.* iv (1862) 146. N. decompositum *var.* glabellum *Hook. and Bak. Syn. Fil.* (1873) 281.

Kermadec Islands, North and South Islands: In dry woods from the North Cape to Foveaux Strait, not uncommon. Sea-level to 1500 ft.

Also in Australia and several of the Polynesian islands. Closely allied to *D. decomposita*, but sufficiently distinct in the short (not creeping) rhizome, the nearly glabrous stipes, the smaller dark-green and glossy tufted fronds, with a narrower outline, and with the surfaces glabrous except a reddish pubescence on the rhachis and costae.

4. **D. velutina** *O. Kuntze Rev. Gen. Pl.* ii (1891) 814.—Rhizome short, stout, erect. Stipes 9–18 in. long, firm, erect, densely villose-pubescent above, clothed at the base with large red-brown subulate scales. Fronds tufted at the top of the rhizome, 9–18 in. long, almost the same in breadth, broadly deltoid or pentangular, acuminate, reddish-brown, soft and membranous, clothed on both surfaces with copious short silky hairs, 2–3-pinnate or in large specimens 4-pinnate at the base; rhachises densely silky. Lower primary pinnae much the largest, 6–12 in. long, deltoid, the lowest secondary pinna much longer than the rest and deflexed; upper pinnae gradually smaller, oblong-deltoid to lanceolate-deltoid, acuminate. Secondary pinnae close, numerous, lanceolate, deeply pinnatifid or again pinnate. Pinnules oblong-ovate or oblong, obtuse, deeply obtusely lobed or pinnatifid. Sori rather small, copious; indusium pubescent, often glandular.—Nephrodium velutinum *Hook. f. Fl. Nov. Zel.* ii (1855) 39, t. 80; *Handb. N.Z. Fl.* (1864) 378; *Hook. Sp. Fil.* iii (1860) 145; *Hook. and Bak. Syn. Fil.* (1873) 281;

Thoms. N.Z. Ferns (1882) 83; *Field N.Z. Ferns* (1890) 132, t. 20, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 1004. Aspidium velutinum *A. Rich. Fl. Nouv. Zel.* (1832) 70; *A. Cunn. Precur.* (1836) n. 222; *Raoul Choix* (1846) 38.

North and South Islands: Dry woods from the North Cape to Otago, but rather local in the South Island. Sea-level to 1000 ft.

Allied to *N. decomposita*, but easily separated by the more membranous and flaccid reddish-brown fronds, densely clothed with a short velvety pubescence. Apparently confined to New Zealand.

5. **D. setigera** *O. Kuntze Rev. Gen. Pl.* ii (1891) 813.—Rhizome short. Stipes 1–2 ft. long or more, firm, erect, straw-coloured, slightly paleaceous at the base, smooth and glabrous above. Fronds tufted, 1–3 ft. long, 9–18 in. broad, ovate or ovate-lanceolate, acuminate, pale-green, membranous, 2–3-pinnate; main rhachis stramineous, naked towards the base, densely clothed with fibrillose hairs above, as are the secondary rhachises; under-surface of frond and veins hispid with long white spreading needle-like hairs. Lower primary pinnae 9–12 in. long, ovate-lanceolate, acuminate, the upper gradually smaller and narrower; secondary pinnae lanceolate, deeply pinnatifid or again pinnate. Pinnules $\frac{1}{6}$–$\frac{1}{4}$ in. long, linear-oblong, obtuse, deeply lobed or pinnatifid, the margins usually recurved. Sori small, copious, 6–10 to a pinnule. Indusium small, soon deciduous.—Nephrodium setigerum *Hook. and Bak. Syn. Fil.* (1873) 284; *Cheesem. Man. N.Z. Fl.* (1906) 1004. Cheilanthes setigera *Blume Enum.* (1828) 138. Hypolepis setigera *Hook. Sp. Fil.* ii (1858) 62. Nephrodium tenericaule *Hook. Sp. Fil.* iv (1863) 142, t. 269; *Cheesem. in Trans. N.Z. Inst.* xx (1888) 178.

Kermadec Islands: Ravines on the north side of Sunday Island, not uncommon, *T. F. C.*; in forest and near fumaroles, *W. R. B. Oliver!*

Abundant throughout Polynesia, and ranging from tropical Australia to Malaya, India, China, and Japan.

6. **D. punctata** *C. Christen. Ind. Fil.* (1905) 287.—Rhizome long, creeping, villous with rufous spreading hairs. Stipes 6–18 in. long, firm, erect, red-brown, densely glandular-pubescent and viscous, rough with minute raised points. Fronds scattered along the rhizome, very variable in size, from $\frac{1}{2}$–3 ft. long, 3–18 in. broad, ovate-deltoid to lanceolate-deltoid, acuminate, rather membranous, glandular-pubescent on both surfaces, 3-pinnate; rhachis viscid-pubescent like the stipes. Primary pinnae in rather distant pairs, 2–10 in. long or more, 1–6 in. broad, narrow-deltoid to lanceolate, acuminate; secondary oblong or linear-oblong, acute or obtuse, deeply pinnatifid or again pinnate. Pinnules or segments oblong, crenate or angulate-dentate or pinnatifid. Veins free, once or twice forked. Sori rather large, orbicular, in 2 rows in each pinnule, close to the margin, often copious and covering the whole under-surface.—Polypodium punctatum *Thunb. Fl. Jap.* (1784) 337; *Hook. and Bak. Syn. Fil.* (1873) 312; *Benth. Fl. Austral.* vii (1872) 764; *Thoms. N.Z. Ferns* (1882) 86; *Field N.Z.* [illegible] (1890) [illegible] *esem. Man. N.Z. Fl.* (1906) 1008. 1806) 92, t. 241; *Hook. f. North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands: Abundant throughout. Sea-level to 2500 ft.

With the exception of Africa, this is universally distributed throughout the tropics and the South Temperate Zone, advancing as far northwards as Japan. It is often confused with *Hypolepis tenuifolia*, which it much resembles in habit and in the shape of the frond. But the stipes and rhachis are markedly viscid-pubescent, the frond glandular-hairy on both surfaces, and the sori are not so close to the margin, and are not covered by a recurved lobule.

7. **D. pennigera** *C. Christen. Ind. Fil.* (1905) 223.—Rhizome stout, erect, sometimes lengthened into a short caudex 1–2 ft. high, clothed with fibrous rootlets and the bases of the old stipites. Stipes 6–12 in. long, stout, rather succulent, more or less clothed with large ovate-lanceolate brownish scales near the base, smooth and glabrous above. Fronds 2–5 ft. long, 9–18 in. broad, oblong-lanceolate, acuminate, thin and membranous, glabrous, pinnate, pinnatifid at the apex; rhachis smooth, glabrous or slightly hairy above. Pinnae numerous, opposite or nearly so, spreading, 3–9 in. long, $\frac{1}{3}$–$1\frac{1}{4}$ in. broad, the lower ones gradually reduced, narrow linear-oblong or linear-lanceolate, acuminate, truncate or almost auricled at the base, pinnatifid about half-way to the midrib; lobes oblong or ovate-oblong, slightly falcate, obtuse, entire or obscurely sinuate, basal ones often greatly lengthened. Veins pinnate in the lobes; veinlets 6–10 on each side, the 2 lowest pairs uniting at the tips with those of the adjoining lobes. Sori one to each veinlet, forming two rows much nearer the midrib than the margin.—Polypodium pennigerum *Forst. f. Prodr.* (1786) 444; *Hook. f. Handb. N.Z. Fl.* (1864) 381; *Hook. Sp. Fil.* v (1864) 7; *Hook. and Bak. Syn. Fil.* (1873) 317; *Thoms. N.Z. Ferns* (1882) 87; *Field N.Z. Ferns* (1890) 137, t. 25, f. 3, *and* t. 26, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 1009. P. subsimile *Col. in Trans. N.Z. Inst.* xx (1888) 233. Goniopteris pennigera *J. Smith Lond. Journ. Bot.* iv (1841) 54; *Hook. f. Fl. Nov. Zel.* ii (1855) 40. Aspidium pennigerum *Swartz Syn. Fil.* (1806) 49; *A. Rich. Fl. Nouv. Zel.* (1832) 67; *A. Cunn. Precur.* (1836) n. 217; *Raoul Choix* (1846) 38. Nephrodium pennigerum *Presl Rel. Haenk.* (1825) 35.

Var. **Hamiltoni** *Col. in Trans. N.Z. Inst.* xiv (1882) 338.—Smaller and more delicate, pale-green. Fronds 1–2 ft. long, 3–5 in. broad; pinnae irregular, crisped, pinnatifid three-quarters of the way to the midrib or more; lobes coarsely and sharply irregularly dentate. Veinlets confined to the lobes, the lowest pair not meeting those of the adjoining lobes. Sori midway between the midrib and the margin. A very peculiar plant, but possibly only an abnormal state.

North and South Islands, Chatham Islands: From the North Cape to Foveaux Strait, abundant in woods by the side of streams, &c. Sea-level to 2000 ft. Var. *Hamiltoni*: Kereru (Hawke's Bay), *A. Hamilton!*

A very distinct and well-marked species. According to Christensen, it occurs in Polynesia as well as in New Zealand. Mr. Carse has pointed out to me that in large specimens the basal lobes of the pinnae are often greatly lengthened, a peculiarity that does not seem to have been mentioned in previous descriptions.

8. **D. parasitica** *O. Kuntze Rev. Gen. Pl.* ii (1891) 811.—Rhizome very shortly creeping or tufted and erect, densely rooting. Stipes 9–24 in. long, slender, greenish, naked or pubescent with soft spreading hairs. Fronds 1–3 ft. long, 6–12 in. broad, oblong-lanceolate, acuminate, gradually narrowed at the base, pale-green, membranous and flaccid, sparingly pilose on both surfaces or almost glabrous when old, pinnate; rhachis pale, pilose with spreading hairs. Pinnae numerous, the lower ones gradually dwarfed, spreading, sessile, 3–6 in. long, about $\frac{3}{4}$ in. broad, lanceolate, acuminate,

pinnatifid about half-way to the midrib; lobes short, oblong, obtuse, entire or nearly so. Veins pinnate in the lobes; veinlets 5–8 on each side, the lower ones uniting at the tips with those of the adjoining lobes. Sori copious, about half-way between the margin and the midrib. Indusium cordate-reniform, usually villous. — Polypodium parasiticum *Linn. Sp. Plant.* (1753) 1090. Nephrodium molle *R. Br. Prodr.* (1810) 149; *Hook. Sp. Fil.* iv (1862) 67; *Hook. f. Handb. N.Z. Fl.* (1864) 177; *Hook. and Bak. Syn. Fil.* (1873) 293; *Thoms. N.Z. Ferns* (1882) 84; *Field N.Z. Ferns* (1890) 133, t. 23, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 1006. Aspidium molle *Swartz Syn. Fil.* (1806) 49; *Benth. Fl. Austral.* vii (1878) 756. Polypodium nymphale *Forst. f. Prodr.* (1786) n. 442.

Kermadec Islands: Sunday Island, not uncommon, *McGillivray, T. F. C., W. R. B. Oliver!* North Island: Auckland—North Cape district, a small patch by the side of the Mangatete Stream, flowing into Rangaunu Harbour, *R. H. Matthews!* Thermal-springs district, by the banks of the Otumakokori, or Boiling River (near Waiotapu), *Captain G. Mair! T. F. C., T. Kirk!* margins of hot springs at Wairakei (Taupo), *C. J. Norton! T. F. C.*

Abundant in tropical and warm temperate countries almost throughout the world.

9. **D. gongylodes** *O. Kuntze Rev. Gen. Pl.* ii (1891) 811.—Rhizome long, stout, creeping, sparingly clothed with blackish-brown scales. Stipes 6–14 in. long, smooth, erect, almost black at the base, brownish above, naked or with a few chaffy scales. Fronds 6–18 in. long without the stipes, 3–9 in. broad, oblong or ovate-oblong, acuminate, somewhat rigid, coriaceous, glabrous, pinnate; rhachis smooth, naked. Pinnae 9–15 pairs, subopposite, ascending or spreading, the lower ones not reduced in size, 2–5 in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, linear-lanceolate, pinnatifid from $\frac{1}{3}$ to $\frac{1}{2}$ the way to the midrib; lobes spreading, ovate or ovate-triangular, subacute or obtuse, entire or nearly so. Veins pinnate in each lobe; veinlets 6–8 on each side, the lower ones united at the tips with those of the adjoining lobes. Sori copious, nearer the margin than the midrib, mostly placed in the lobes, but usually extending below them as well.—Aspidium gongylodes *Schkuhr Krypt. Gew.* (1809) 193. Nephrodium unitum *R. Br. Prodr.* (1810) 149; *Hook. f. Handb. N.Z. Fl.* (1864) 749; *Hook. and Bak. Syn. Fil.* (1873) 289; *Thoms. N.Z. Ferns* (1882) 83; *Field N.Z. Ferns* (1890) 134, t. 23, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1005. N. inaequilaterum *Col. in Trans. N.Z. Inst.* xx (1888) 229. Aspidium unitum *Swartz Syn. Fil.* (1806) 47; *Benth. Fl. Austral.* vii (1878) 755.

North Island: Swamps in the North Cape district, at Houhoura, Waihi, Rangaunu Harbour, Ahipara, &c., *J. B. Simpson! R. H. Matthews! T. F. C.;* hot springs at Miranda, Thames, *J. Adams!* hot-water swamps in the Thermal-springs district, not uncommon from Maketu and Rotorua to Waiotapu, Rotokawa, Wairakei, and Tokaanu, *Captain G. Mair! T. Kirk! T. F. C., Norton! Field,* &c. Sea-level to 1800 ft.

An abundant fern in most tropical and warm-temperate countries.

11. **ARTHROPTERIS** J. Smith.

Rhizome long, slender, climbing or creeping. Stipes articulated near its base, or a little distance above the rhizome. Fronds scattered along the rhizome, pinnate; pinnae articulated on the rhachis. Veins simple or forked or pinnate, venules free. Sori globose, punctiform, situated on the tip of a vein. Indusium reniform, or altogether absent in the New Zealand species. Sporangia girt by an incomplete vertical ring.

A small genus of 3 species; one (*A. altescandens*) confined to the island of Juan Fernandez; another (*A. obliterata*) spread over the tropics of Asia, Africa, Australia, and Polynesia; and the New Zealand species, which is also found in Australia and New Caledonia.

1. **A. tenella** *J. Smith in Hook. f. Fl. Nov. Zel.* ii (1855) 43, t. 82.—Rhizome very long, slender, rigid, wiry, climbing up the trunks of trees or over rocks, clothed with chestnut-brown scales with a dark base. Stipes short, 1–3 in. long, jointed near the rhizome, smooth or more or less scaly. Fronds scattered along the rhizome, erect or pendulous, 1–2 ft. long, 2–5 in. broad, linear-oblong or lanceolate, dark-green, thinly coriaceous, quite glabrous, pinnate; rachis smooth or slightly scaly. Pinnae distant, alternate, shortly stipitate, articulate on the rhachis, spreading, 1½–3 in. long, ¼–½ in. broad, lanceolate, attenuate at the tip, obliquely cuneate at the base, entire or obscurely undulate-crenate. Veins all free, once or twice forked. Sori globose, in 2 series in each pinnule, almost close to the margin.—Polypodium tenellum *Forst. f. Prodr.* (1786) n. 440; *A. Cunn. Precur.* (1836) n. 176; *Raoul Choix* (1846) 37; *Hook. Sp. Fil.* iv (1862) 217; *Hook. f. Handb. N.Z. Fl.* (1864) 380; *Hook. and Bak. Syn. Fil.* (1873) 337; *Benth. Fl. Austral.* vii (1878) 764; *Thoms. N.Z. Ferns* (1882) 88; *Field N.Z. Ferns* (1890) 139, t. 4, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 1011.

North Island: In woods from the Three Kings Islands and the North Cape to Cook Strait, but often local. South Island: Vicinity of Nelson, *T. Kirk;* Banks Peninsula, *Armstrong.*

Also in Norfolk Island, Australia, and New Caledonia.

12. **NEPHROLEPIS** Schott.

Rhizome short and indistinct, or long and creeping, sometimes emitting long wiry creeping and rooting stolons, from which new plants originate. Fronds long and narrow, coriaceous or submembranous, pinnate; pinnae jointed upon the rhachis, often deciduous, entire or crenate-serrate, upper surface frequently marked with white cretaceous dots. Veins free. Sori roundish, dorsal, placed on the tip of the upper branch of a vein, usually close to the margin. Indusium cordate or reniform or almost lunate, attached by a broad base. Sporangia stalked, surrounded by an incomplete vertical ring, bursting transversely.

A small genus of 7 or 8 species, widely distributed in the tropical regions of both hemispheres. The two New Zealand species have the range of the genus.

Pinnae ½–1 in. long, oblong or linear-oblong, obliquely cordate at the base .. .. 1. *N. cordifolia.*
Pinnae 1½–3 in. long, oblong-lanceolate, usually obliquely truncate at the base .. .. 2. *N. exaltata.*

1. **N. cordifolia** *Presl Tent. Pterid.* (1836) 79.—Rhizome short, suberect or oblique, emitting numerous long and wiry scaly stolons, which root here and there and produce new plants, sometimes bearing small scaly tubers. Stipes short, 1–4 in. long, red-brown, glossy, more or less clothed with deciduous linear scales. Fronds numerous, tufted, 1–3 ft. long, 1½–2 in. broad, linear-lanceolate, acuminate, pale-green, membranous, pinnate; rhachis usually shaggy with linear flexuose scales. Pinnae very numerous, close-set, often imbricated, horizontal, ½–1 in. long, ¼–½ in. broad, oblong

or linear-oblong, obtuse or subacute, cordate at the base, the upper edge distinctly auricled, the lower shorter and rounded; margins crenate-toothed; the lower pinnae shorter and broader and sterile. Sori in two rows on the pinnae, rather nearer the margin than the midrib. Indusium reniform, firm, membranous.—*Hook. and Bak. Syn. Fil.* (1873) 300; *Thoms. N.Z. Ferns* (1882) 85; *Field N.Z. Ferns* (1890) 134, t. 20, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1006. N. tuberosa *Presl Tent. Pterid.* (1836) 79; *Hook. Sp. Fil.* iv (1862) 151; *Hook. f. Handb. N.Z. Fl.* (1864) 379. N. flexuosa *Col. in Trans. N.Z. Inst.* xx (1888) 231. Aspidium cordifolium *Swartz Syn. Fil.* (1806) 45; *Benth. Fl. Austral.* vii (1878) 754.

Kermadec Islands: Sunday Island, not uncommon, *W. R. B. Oliver!* North Island: Auckland—Thermal-springs district, in localities heated by warm water; Otumakokori Stream (near Waiotapu), *Captain G. Mair! T. Kirk! T. F. C.;* Wairakei, Karapiti, and other localities at Taupo, *Hochstetter, C. J. Norton! T. F. C.*

An abundant tropical fern, extending northwards to Japan and southwards to New Zealand.

2. **N. exaltata** *Schott Gen. Fil.* (1834) t. 3.—Rhizome short, indistinct, emitting numerous long wiry creeping stolons. Stipes 3–9 in. long, stout, erect, deciduously scaly. Fronds numerous, 1–3 ft. long, 4–5 in. broad, oblong-lanceolate, rather coriaceous, pinnate; rhachis and costae and sometimes the under-surface of the pinnae more or less scaly-tomentose or woolly. Pinnae numerous, close-set, horizontally spreading, $1\frac{1}{2}$–3 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, lanceolate or oblong-lanceolate, acute, broadly obliquely truncate or subcordate at the base, the upper edge slightly auricled, the lower rounded; margins crenate-serrate. Sori close to the margin, numerous, rather small. Indusium firm, almost coriaceous, distinctly reniform.—*Hook. Sp. Fil.* iv (1862) 152; *Hook. and Bak. Syn. Fil.* (1873) 301; *Cheesem. in Trans. N.Z. Inst.* xx (1888) 178; *Man. N.Z. Fl.* (1906) 1007. Aspidium exaltatum *Swartz Syn. Fil.* (1806) 45; *Benth. Fl. Austral.* vii (1878) 754.

Kermadec Islands: Sunday Island, sandy flats in Denham Bay, *T. F. C.;* near fumaroles in Denham Bay and in main crater, *W. R. B. Oliver!*

An abundant tropical fern all round the world.

13. **LEPTOLEPIA** Mettenius.

Rhizome long and creeping, clothed with narrow-linear scales. Stipes not articulated on the rhizome. Fronds large, many times pinnate; ultimate segments narrow-linear. Veins free. Sori terminal at the tip of a short lateral veinlet. Indusium attached to the vein, broadly ovate or almost orbicular, its free margin toothed or scalloped. Sporangia numerous, girt by an incomplete vertical ring.

A monotypic genus confined to New Zealand.

1. **L. novae-zealandiae** *Kuhn Chaetopt.* (1882) 348.—Rhizome long, branched, wide-creeping, as thick as a quill, clothed with yellowish-brown linear scales. Stipes 6–18 in. long, red-brown, firm, erect, rough and bristly at the base, smooth and polished above. Fronds 1–2 ft. long, 6–12 in. broad, ovate-oblong to deltoid, acuminate, firm but scarcely coriaceous, tripinnate; rhachis flexuose, channelled above, glabrous or pubescent at the axils. Primary pinnae oblong-lanceolate, acuminate;

secondary about the same shape, pinnate below, pinnatifid at the tips. Pinnules about ½ in. long, ovate-lanceolate, deeply pinnatifid; ultimate segments or lobes very narrow, acute. Sori very numerous, placed at the tip of a short lateral veinlet on the lobes of the pinnules. Indusium broadly ovate or almost orbicular, membranous, jagged, attached to the tip of the vein under the sorus, its sides quite free.—Davallia novae-zelandiae *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 182; *Hook. Sp. Fil.* i (1846) 158, t. 51B; *Garden Ferns*, 51; *Hook. f. Fl. Nov. Zel.* ii (1855) 19; *Handb. N.Z. Fl.* (1864) 358; *Hook. and Bak. Syn. Fil.* (1873) 91; *Thoms. N.Z. Ferns* (1882) 49; *Field N.Z. Ferns* (1890) 74, t. 18, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 956. D. hispida *Heward mss. ex Sp. Fil.* i (1846) 158. Acrophorus hispidus *Moore in Proc. Linn. Soc.* ii (1854) 286.

North and South Islands: In woods from the Bay of Islands southwards to Foveaux Strait, but often local. Sea-level to 2000 ft.

A very handsome and distinct species, with an unusually finely cut frond. It has been referred by turns to the genera (or divisions of *Davallia*) *Leucostegia*, *Microlepia*, and *Acrophorus*, and has finally been made the type of a new genus by Mettenius.

14. **DAVALLIA** Smith.

Rhizome stout and wide-creeping, paleaceous. Stipes always articulated on the rhizome. Fronds in the majority of the species ample, 3–4-pinnate, more rarely pinnate or bipinnate; texture usually coriaceous. Veins simple or forked, free. Sori close to or at the margin of a segment of the frond, terminating a vein or veinlet. Indusium attached by both its base and sides, open at the top, narrow cup-shaped or cylindrical. Sporangia numerous, girt by an incomplete vertical ring, bursting transversely.

In this work I have limited the genus *Davallia* to the meaning attached to it by Diels and Christensen. It still contains, however, the sections *Eudavallia*, *Leucostegia*, *Prosaptia*, and *Scyphularia* of the "Synopsis Filicum," and thus includes between 50 and 60 well-authenticated species. These are mostly distributed in the tropics of the Eastern Hemisphere; but the centre of the genus is doubtless in the Polynesian and Malayan archipelagos. The single New Zealand species is closely allied to the Madeiran and Canary Island *D. canariensis*.

[*Davallia Forsteri* Carruthers is a name applied to Forster's *Adiantum clavatum*, a plant said to have been gathered in Dusky Sound during Cook's second voyage, but not since observed. Mr. Baker remarks that it is very close to the Polynesian *Odontosoria scoparia*; and Mr. W. R. B. Oliver, who has recently compared Forster's specimens with that plant, informs me that the two are identical. In all probability there has been an accidental admixture of specimens.]

1. **D. Tasmani** *Cheesem. in Trans. N.Z. Inst.* xxiii (1891) 416.—Rhizome long, stout, as thick as the finger, wide-creeping, densely clothed with chestnut-brown subulate ciliated scales. Stipes strong, rigid, smooth, 3–9 in. long. Fronds 4–12 in. long, 3–9 in. broad, broadly deltoid or pentagonal, very thick and coriaceous, quite smooth and glabrous, 2–3-pinnatifid. Lower pinnae much the largest, broadly deltoid or rhomboidal; upper narrower, ovate or lanceolate. Pinnules oblong, cut down nearly to the base into 6–9 segments; segments short, oblong, obtuse. Sori very numerous, usually one to each segment, marginal, the segment usually produced on the outer side into a stout projecting horn. Indusium narrow cup-shaped, attached by the sides as well as the

base.—*Field N.Z. Ferns* (1890) 75, t. 24, f. 5; *Bak. in Ann. Bot.* v (1890–91) 201; *Cheesem. Man. N.Z. Fl.* (1906) 955; *Ill. N.Z. Fl.* ii (1914) t. 237.

North Island: Three Kings Islands, abundant, *T. F. C.*

Very close to the northern *D. canariensis* L., but stouter and more coriaceous, and not so finely cut.

15. **LINDSAYA** Dryander.

Usually small subcoriaceous bright-green ferns. Rhizome creeping or short and tufted. Fronds pinnate or 2–3-pinnatifid; pinnae often 1-sided. Veins free, or anastomosing in a few species not found in New Zealand. Sori forming a continuous or more or less interrupted line within the margin of the frond and parallel to it, placed at the apex of 2 or more veins and uniting them. Indusium apparently double and 2-valved, opening outwards; upper valve formed of the more or less altered margin of the frond; lower valve thin, membranous, continuous. Sporangia numerous, stalked, bursting transversely; ring vertical, incomplete.

Understood in the sense of the "Synopsis Filicum," this is a genus of about 75 species, mainly found in the tropics of both hemispheres. Two of the New Zealand species extend to Australia, Tasmania, and Polynesia, one of them reaching New Caledonia as well, the remaining one is endemic.

* *Eulindsaya.* Pinnae unilateral.

Fronds linear, simply pinnate; pinnae small, flabellate ..	1. *L. linearis.*

** *Isoloma.* Pinnae equilateral.

Fronds 2–3-pinnatifid, dark-green, oblong-lanceolate, broadest at the base; ultimate segments obovate, rounded at the tip ..	2. *L. cuneata.*
Fronds 2–3-pinnatifid, pale-green, lanceolate, not broadest at the base; ultimate segments linear-cuneate, truncate at the tip ..	3. *L. viridis.*

1. **L. linearis** *Swartz Syn. Fil.* (1806) 118, 318, t. 3.—Rhizome slender, creeping, clothed with yellowish-brown scales. Stipes 2–9 in. long, slender, flexuous, wiry, dark red-brown, smooth and shining. Fronds 3–8 in. long, about $\frac{1}{2}$ in. broad, narrow-linear, membranous, pinnate; barren ones shorter and broader than the fertile, often prostrate; fertile always erect; rhachis naked, glossy. Pinnae of the fertile fronds $\frac{1}{6}$–$\frac{1}{3}$ in. long, flabellate or cuneate, sessile or nearly so, not lobed or very indistinctly so, revolute when dry. Sori forming a continuous line along the upper edge. Indusium broad, membranous; both valves minutely and irregularly laciniate. Pinnae of the barren fronds $\frac{1}{4}$–$\frac{1}{2}$ in. long or more, deeply lobed or incised. —*A. Rich. Fl. Nouv. Zel.* (1832) 85; *A. Cunn. Precur.* (1836) n. 213; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 206; *Hook. f. Fl. Nov. Zel.* ii (1855) 19; *Handb. N.Z. Fl.* (1864) 359; *Hook. and Bak. Syn. Fil.* (1873) 104; *Benth. Fl. Austral.* vii (1878) 719; *Thoms. N.Z. Ferns* (1882) 51; *Field N.Z. Ferns* (1890) 77, t. 19, f. 4, 4A; *Cheesem. Man. N.Z. Fl.* (1906) 958. L. trilobata *Col. in Trans. N.Z. Inst.* xvi (1884) 345.

North and South Islands, Stewart Island, Chatham Islands. From the North Cape southwards, usually on clay hills or in cold swampy soils, most plentiful to the north of the East Cape, rare and local in the South Island. Sea-level to 2000 ft.

Also found throughout the whole of eastern Australia and Tasmania, in Norfolk Island, and in New Caledonia. Mr. Colenso's *L. trilobata*, which appears to be the most abundant state in New Zealand, only differs in the pinnae of the barren frond being rather more deeply lobed than usual.

2. **L. cuneata** *C. Christen. Ind. Fil.* (1905) 25.—Rhizome creeping, slender, clothed with reddish brown scales. Stipes 3–8 in. long, rather rigid, slender, wiry, angled, polished, glabrous or slightly scaly towards the base. Fronds 3–8 in. long, 1½–4 in. broad, oblong-lanceolate or linear-oblong, more rarely ovate-oblong, subcoriaceous, dark-green, bipinnate. Primary pinnae nearly opposite, 1–3 in. long, lanceolate, erecto-patent, pinnatifid above, pinnate below. Pinnules or segments obovate or rounded-cuneate, entire or more or less toothed or lobed, rarely again pinnatifid. Veins obscure, flabellately branched. Sori forming a continuous intramarginal line round the apex of the lobes.—*Dryand. in Trans. Linn. Soc.* iii (1797) 43, t. 11; *A. Rich. Fl. Nouv. Zel.* (1832) 85; *A. Cunn. Precur.* (1836) n. 214; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 218; *Hook. f. Fl. Nov. Zel.* ii (1855) 19; *Handb. N.Z. Fl.* (1864) 359; *Hook. and Bak. Syn. Fil.* (1873) 110; *Benth. Fl. Austral.* vii (1878) 720; *Thoms. N.Z. Ferns* (1882) 52; *Field N.Z. Ferns* (1890) 78, t. 19, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 958. Adiantum cuneatum *Forst. f. Prodr.* (1786) n. 461.

Var. **Lessonii** *Hook. f. Fl. Nov. Zel.* ii (1855) 19.—Fronds simply pinnate or 2-pinnate at the base alone; pinnae oblong-lanceolate, entire or lobed or pinnatifid.—L. Lessonii *Bory in Duper. Voy. Coq.* i (1828) 278, t. 37, f. 2; *A. Rich. Fl. Nouv. Zel.* (1832) 84; *A. Cunn. Precur.* (1836) n. 212; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* i (1846) 217.

North and South Islands: From Hokianga southwards to Foveaux Strait, common in the North Island, local on the eastern side of the South Island. Sea-level to 2500 ft.

Also in Australia, Tasmania, and the Fiji Islands.

3. **L. viridis** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 174.—Rhizome very short, suberect. Stipites densely tufted at the top of the rhizome, 1–4 in. long, slender, wiry, dark chestnut-brown, angled, smooth and polished, glabrous except a tuft of pale-brown scales at the base. Fronds 6–14 in. long, 1–1½ in. broad, lanceolate, acuminate, pale-green, subcoriaceous, 2–3-pinnatifid; rhachis slender, flexuose, shining, naked. Primary pinnae alternate, ascending, the lower ones much reduced in size, rhomboid-lanceolate; secondary obversely deltoid, simple or deeply lobed or again flabellately pinnate. Ultimate segments about ⅙ in. long, cuneate or linear-cuneate, truncate. Veins simple or forked. Sori very numerous, at the tips of the segments. Indusium membranous, transversely oblong, from rather broader than long to twice as broad as long; outer valve (tip of the segment) irregularly erose.—*Bak. in Journ. Bot.* (1875) 109; *T. Kirk in Trans. N.Z. Inst.* x (1878) 396; *Thoms. N.Z. Ferns* (1882) 51; *Field N.Z. Ferns* (1890) 79, t. 21, f. 2; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 238. L. trichomanoides (*in part*) *Hook. Sp. Fil.* i (1846) 218; *Hook. f. Fl. Nov. Zel.* ii (1855) 19; *Handb. N.Z. Fl.* (1864) 359 (*not of Dryand.*). L. microphylla *Hook. and Bak. Syn. Fil.* (1873) 110 (*the New Zealand plant, not of R. Br.*).

North Island: Auckland—Great Barrier Island, *T. Kirk, Winkelmann!* Little Barrier Island, *Miss Shakespear!* Thames, *Adams!* Henderson's Creek, *T. F. C.;* Huia Creek, *T. Kirk;* near Mauku, *H. Carse;* between Tauranga and Rotorua, *Colenso!* East Cape district, *Bishop Williams.* Taranaki—Mount Egmont Ranges, *J. M. Brame.* Wellington—Upper Wanganui, and from thence to the base of the Tararua Range,

H. C. Field. SOUTH ISLAND: Nelson—Massacre Bay, *Lyall;* Torrent Bay, *Kingsley.* Westland—Near Hokitika, *W. H. Tipler;* Giles Creek, near Westport; Millerton; near Charleston, *W. Townson!* Otago—Sounds of the West Coast, *Buchanan.*

A very beautiful and distinct species, usually found on dripping rocks by waterfalls, or on the mossy banks of streams.

16. **ATHYRIUM** Roth.

Rhizome short, stout, erect or ascending, rarely creeping, chaffy or scaly at the top. Stipes few or many, tufted at the top of the rhizome. Fronds 2-3-pinnatifid, usually herbaceous in texture. Veins free. Sori placed along the veins, short, oblong, thick and swollen, curved or inflexed, rarely quite straight. Indusium inflated, splitting irregularly; sometimes two indusia are placed side by side on opposite sides of the vein, opening outwards as in *Diplazium.* Sporangia stalked, girt by an incomplete vertical ring.

A genus of 60 or 70 species, intermediate in character between the typical *Asplenia* and *Diplazium.* The genus has an almost world-wide range.

1. **A. umbrosum** *Presl Tent. Pterid.* (1836) 98.—Rhizome short, stout. Stipes 1–2 ft. long, stout, erect, scaly towards the base, smooth and naked above, brownish-green. Fronds variable in size, 1–4 ft. long without the stipes, 9 in. to 3 ft. broad, broadly ovate or deltoid, spreading, often drooping towards the tip, pale-green, membranous, flaccid, 2–3-pinnate; rhachis slender, flexuous, naked. Primary pinnae rather distant, 6–18 in. long, ovate-lanceolate to oblong-ovate, acute or acuminate; secondary 1–2 in. long, lanceolate, deeply pinnatifid or again pinnate. Ultimate segments $\frac{1}{4}$–$\frac{1}{2}$ in. long, oblong or oblong-lanceolate, acute, sessile and decurrent, usually deeply inciso-crenate; veins pinnate, simple or forked. Sori copious, usually about 5–6 to each pinnule, short, oblong. Indusium large, tumid, membranous.—Asplenium umbrosum *J. Smith in Hook. Lond. Journ. Bot.* iv (1841) 174; *Hook. and Bak. Syn. Fil.* (1873) 229; *Benth. Fl. Austral.* vii (1878) 749; *Thoms. N.Z. Ferns* (1882) 77; *Field N.Z. Ferns* (1890) 125, t. 5, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 995. A. australe *Brack. U.S. Expl. Exped.* xvi (1854) 173; *Hook. Sp. Fil.* iii (1860) 232; *Hook. f. Handb. N.Z. Fl.* (1864) 374. A. Brownii *J. Smith ex Hook. f. Fl. Nov. Zel.* ii (1855) 36; *Hook. Ic. Plant.* t. 978. Allantodia australe *R. Br. Prodr.* (1810) 149. A. tenera *R. Br. l.c.; A. Cunn. Precur.* (1836) n. 186; *Raoul Choix* (1846) 37. Polypodium umbrosum *Ait. Hort. Kew,* iii (1789) 466.

NORTH ISLAND: Not uncommon from the Bay of Islands to the East Cape and Taranaki, from thence somewhat rare and local to Cook Strait, usually on calcareous or alluvial soils. SOUTH ISLAND: Nelson—*Travers;* near Foxhill, *T. F. C.;* West Wanganui, *Kingsley.* Westland—Banks of Buller River, near Westport, *W. Townson!*

Also found in Australia and Tasmania, the Malay Archipelago, India, tropical Africa to the Canary Islands, the Azores, and Madeira.

17. **DIPLAZIUM** Swartz.

Rhizome erect and sometimes arborescent, or slender and wide-creeping. Stipes not articulated to the rhizome. Fronds varying in size, 1–5 ft., 1–3-pinnate; texture herbaceous or rarely subcoriaceous. Veins forked or

pinnate, free except in the sections *Anisogonium* or *Hemidictyum*. Sori linear, along opposite sides of many of the veins, each side having an indusium of its own. Sporangia stalked, girt by an incomplete vertical ring.

A genus of nearly 200 species, widely diffused in the tropics of both hemispheres.

1. **D. japonicum** *Bedd. Ferns Brit. Ind. Suppl.* (1876) 12.—Rhizome long, slender, creeping, branched, densely scaly at the tip. Stipes 3–9 in. long, slender, pale-brown or straw-coloured, scaly when young, especially near the base. Fronds 6–12 in. long without the stipes, $2\frac{1}{2}$–5 in. broad, ovate-lanceolate, long-acuminate, pale-green, thin and membranous, glabrous on both surfaces or sprinkled with a few weak hairs, pinnate below, pinnatifid towards the apex; rhachis slender, slightly scaly. Pinnae spreading, rather distant, $1\frac{1}{2}$–3 in. long, lanceolate, acuminate, deeply pinnatifid; lobes about $\frac{1}{3}$ in. long, close, oblong, obtuse, slightly toothed or nearly entire. Veins pinnate in the lobes; veinlets 4–6 on each side, simple or forked. Sori linear-oblong, usually occupying all the veinlets, reaching two-thirds of the distance from the midrib to the margin, the lowest one in each lobe usually diplazioid.—Asplenium japonicum *Thunb. Fl. Jap.* (1784) 334; *Hook. and Bak. Syn. Fil.* (1873) 234; *Benth. Fl. Austral.* vii (1878) 750; *Cheesem. in Trans. N.Z. Inst.* xxii (1890) 448; *Man. N.Z. Fl.* (1906) 996. A. Schkuhrii *Hook. Sp. Fil.* iii (1860) 251.

Kermadec Islands: Ravines on Sunday Island, not common, *T. F. C., W. R. B. Oliver!* North Island: Auckland—Banks of the Awanui River (near Kaitaia), *R. H. Matthews! H. Carse!* Okura River (Bay of Islands), *Miss Clarke!* Waiaruhia River (Bay of Islands), *T. H. Trevor!* Northern Wairoa River, *G. E. Smith!*

This appears to be a widely distributed species, ranging through Polynesia to the Malay Archipelago, India, China, and Japan. It is possible that Mr. Kirk's *A. umbrosum* var. *tenuifolium* (Trans. N.Z. Inst. xxiii (1891) 424), of which I have seen no specimens, may be identical with it.

18. **ASPLENIUM** Linn.

Rhizome usually short and thick, more rarely long and creeping. Fronds tufted at the top of the rhizome or scattered, stipitate, pinnate or 2–3-pinnate or decompound, simple and entire in a few species not found in New Zealand. Venation variable, free in the great mass of the species, including those found in New Zealand. Sori linear or oblong, placed upon the veins, more or less oblique with respect to the costa, remote from the margin or close to it when the frond is much divided. Indusium the same shape as the sorus, attached by its side to the vein, straight or rarely curved, flat or tumid, opening towards the costa. Sporangia stalked, surrounded by an incomplete vertical ring, bursting transversely.

Asplenium is one of the largest genera of Ferns, containing about 350 species, distributed through both the tropical and temperate regions of the world. Of the 13 species found in New Zealand 3 appear to be endemic, another is found elsewhere only in Australia, the remaining 9 are widely spread. The New Zealand species present exceptional difficulties to the student, on account of their extreme variability and the manner in which several of them are connected by intermediate forms. Thus *A. obtusatum* and *A. lucidum* not only run into one another, but are connected by transitional varieties with *A. bulbiferum* and *A. flaccidum*. *A. Richardi* almost merges into *A. flaccidum* on the one side and *A. Hookerianum* on the other, while *A. bulbiferum* and *A. flaccidum*, distinct enough in their ordinary states, are almost united by some of their aberrant varieties. With such a complex network of variation it is not surprising that the species are difficult of limitation and their characters arbitrary.

* Fronds pinnate (2-pinnate below in *A. lucidum* var. *Lyallii*). Sori remote from the margin.

Fronds slender, 6–14 in., decumbent or prostrate, rooting at the naked tip. Pinnae $\frac{1}{4}$–$\frac{1}{2}$ in., flabellate	1. *A. flabellifolium.*
Fronds slender, 3–12 in., rigid, erect. Pinnae $\frac{1}{4}$–$\frac{1}{2}$ in., oblong or obovoid	2. *A. Trichomanes.*
Fronds 1–2 ft., coriaceous, not fleshy, brownish-green. Pinnae $1\frac{1}{2}$–4 in. × $\frac{1}{2}$–1 in., broadly lanceolate, acuminate, deeply lobed. Veins close, distinct, flabellately divided at the base of the pinnae	3. *A. adiantoides.*
Characters of *A. adiantoides* but pinnae narrow-lanceolate, caudate	4. *A. caudatum.*
Fronds $\frac{1}{2}$–$1\frac{1}{2}$ ft., thick and fleshy. Pinnae $\frac{3}{4}$–$1\frac{1}{2}$ in., oblong, obtuse. Veins obscure, parallel	5. *A. obtusatum.*
Fronds 1–3 ft., coriaceous, bright-green. Pinnae 2–6 in. × $\frac{3}{4}$–2 in., oblong-lanceolate, acuminate, serrate. Veins obscure, parallel	6. *A. lucidum.*
Fronds 1–$1\frac{1}{2}$ ft., bright shining-green. Pinnae 3–5 in. × $\frac{1}{2}$–$\frac{3}{4}$ in., caudate-acuminate, deeply serrate or pinnatifid	7. *A. scleroprium.*
Fronds 2–10 in. × 1–4 in., greyish-green. Pinnae obtuse or acute, sometimes pinnatifid at the base	8. *A. anomodum.*

** Fronds 2–3-pinnate; segments generally narrow. Sori usually one to each segment, often close to the margin.

Fronds 3–12 in., erect, membranous, usually 2-pinnate. Pinnae and pinnules distinctly stipitate, the latter short, rhomboid-cuneate. Sori few, rather large	9. *A. Hookerianum.*
Fronds 1–4 ft., oblong-lanceolate, erect or drooping, often proliferous, 2–3-pinnate. Pinnules lanceolate, $\frac{1}{2}$–$1\frac{1}{2}$ in. long	10. *A. bulbiferum.*
Fronds 6–12 in., ovate, coriaceous, rigid, erect, 2–3-pinnate. Pinnules ovate-rhomboid, pinnatifid; segments narrow-linear, $\frac{1}{12}$–$\frac{1}{8}$ in. long	11. *A. Richardi.*
Fronds $\frac{1}{2}$–3 ft., pendulous or erect, thick and coriaceous, pinnate or 2-pinnate. Pinnules very narrow-linear ..	12. *A. flaccidum.*
Fronds 1–3 ft., erect or pendulous, broadly ovate or oblong, 3–4-pinnate; pinnules narrow-linear-spathulate ..	13. *A. Shuttleworthianum.*

1. **A. flabellifolium** *Cav. Descr.* (1802) 257.—Rhizome short, stout, clothed at the top with blackish-brown subulate scales. Stipes 1–4 in. long, rarely more, slender, flexuous, smooth or slightly scaly, green above, dark-brown below. Fronds few, tufted at the top of the rhizome, weak, decumbent or prostrate, rooting at the elongated and naked apex, 6–14 in. long, $\frac{1}{2}$–1 in. broad, linear, membranous, flaccid, pinnate; rhachis smooth, green. Pinnae 10–25 pairs, distant, the upper becoming gradually smaller and disappearing some distance below the tip of the rhachis, very variable in size and shape, shortly stipitate, $\frac{1}{4}$–$\frac{1}{2}$ in. long and broad, flabellate or rhomboid-cuneate or orbicular-reniform, sometimes auricled or almost 3-lobed at the base, coarsely crenate-toothed; veins flabellate. Sori several to each pinna, oblique, linear-oblong when young, often confluent when old.—*A. Cunn. Precur.* (1836) n. 192; *Raoul Choix* (1846) 37; *Hook. Exot. Fil.* t. 208; *Sp. Fil.* iii (1860) 146; *Hook. f. Fl. Nov. Zel.* ii (1855) 33; *Handb. N.Z. Fl.* (1864) 372; *Hook. and Bak. Syn. Fil.* (1873) 195; *Benth. Fl. Austral.* vii (1878) 745; *Thoms. N.Z. Ferns* (1882) 73; *Field N.Z. Ferns* (1890) 116, t. 6, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 988.

North and South Islands: Open rocky places from the Bay of Islands to Otago, not uncommon. Sea-level to 2000 ft.

Also in temperate Australia and Tasmania. Sometimes the upper pinnae are produced into naked tips which root like the apex of the frond. This state has been described by Mr. Colenso as var. *ramosum* (Trans. N.Z. Inst. xx (1888) 228).

2. **A. Trichomanes** *Linn. Sp. Plant.* (1753) 1080.—Rhizome short, thick, fibrous, clothed at the top with linear-subulate blackish scales. Stipes 1–4 in. long, naked, dark chestnut-brown, smooth and glossy, narrowly margined above. Fronds tufted at the top of the rhizome, rigid, erect, 3–12 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, linear, subcoriaceous, pinnate; rhachis red-brown, margined throughout. Pinnae 15–40 pairs, spreading, sessile or nearly so, $\frac{1}{4}$–$\frac{1}{2}$ in. long, oblong or obovate, rounded at the tip, obliquely cuneate at the base, sometimes auricled on the upper edge, margins crenate-serrate. Veins few, indistinct, oblique, forked above the middle. Sori oblique, linear-oblong, 3–6 on each side of the pinna, often confluent when old.—*Hook. Sp. Fil.* iii (1860) 136; *Hook. f. Handb. N.Z. Fl.* (1864) 371; *Hook. and Bak. Syn. Fil.* (1873) 196; *Benth. Fl. Austral.* vii (1878) 745; *Thoms. N.Z. Ferns* (1882) 73; *Field N.Z. Ferns* (1890) 110, t. 28, f. 8; *Cheesem. Man. N.Z. Fl.* (1906) 988. A. melanolepis *Col. in Trans. N.Z. Inst.* xx (1888) 227.

North Island: Auckland—Waitomo Caves and Marikopo River, *E. P. Turner!* Hawke's Bay—Kaimanawa Mountains, *Captain G. Mair!* Petane, *A. Hamilton!* Puketapu, *Colenso!* Taranaki—Mount Egmont, *T. F. C.* Wellington—Tararua Range, *Buchanan.* South Island: Not uncommon in mountainous localities throughout. Sea-level to 4000 ft.

Widely distributed in the temperate regions of both hemispheres and on high mountains in the tropics.

3. **A. adiantoides** *C. Christen. Ind. Fil.* (1905) 99.—Rhizome short, stout, creeping, more or less clothed with dark-brown scales. Stipes 6–12 in. long, dark-brown, firm, villous and paleaceous at the base and sometimes throughout. Fronds erect or pendulous, 1–3 ft. long or more, 3–7 in. broad, linear-lanceolate or lanceolate, acuminate, coriaceous, dark-green or brownish-green above, paler beneath, glabrous or deciduously paleaceous, pinnate; rhachis bristly with linear scales or almost glabrous. Pinnae 12–25 pairs, spreading, stipitate, $1\frac{1}{2}$–4 in. long, $\frac{1}{2}$–1 in. broad, lanceolate, finely acuminate, obliquely cuneate at the base, the upper edge broad and rounded or sometimes auricled, the lower edge excised, lobed or almost pinnatifid, lobes sharply incised. Veins distinct, close, erecto-patent, forked, the basal ones almost flabellate. Sori numerous, linear, obliquely diverging from the midrib, almost reaching the margin. Indusium narrow, membranous but firm.—A. falcatum *Lam. Encycl.* ii (1786) 306; *A. Rich. Fl. Nouv. Zel.* (1832) 73; *A. Cunn. Precur.* (1836) n. 187; *Raoul Choix* (1846) 47; *Hook. Sp. Fil.* iii (1860) 160; *Hook. f. Handb. N.Z. Fl.* (1864) 372; *Hook. and Bak. Syn. Fil.* (1873) 308; *Benth. Fl. Austral.* vii (1878) 746; *Thoms. N.Z. Ferns* (1882) 74; *Field N.Z. Ferns* (1890) 117, t. 21, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 989. A polyodon *Forst. f. Prodr.* (1786) n. 428; *A. Cunn. Precur.* (1836) n. 188; *Hook. f. Fl. Nov. Zel.* ii (1855) 34. A. Forsterianum *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 171. Trichomanes adiantoides *Linn. Sp. Plant.* (1753) 1098.

North and South Islands, Stewart Island, Chatham Islands: From the North Cape southwards, not uncommon in woods, often pendulous from trees. Sea-level to 2000 ft.

Also abundant in many parts of tropical Asia and Africa, the Pacific islands, and Australia. Very variable in the size and shape of the pinnae, and the extent to which they are lobed and cut.

4. **A. caudatum** *Forst. f. Prodr.* (1786) n. 432.—Rhizome short, creeping, clothed with dark-brown linear scales. Stipes 6–9 in. long, densely clothed with fibrillose scales or almost naked. Frond 1–2 ft. long, 3–8 in. broad, lanceolate or oblong-lanceolate, acuminate, coriaceous, dark-green, glabrous or deciduously villous, pinnate; rhachis bristly or almost glabrous. Pinnae 15–30 pairs, spreading, stipitate, 1½–4 in. long, ½–¾ in. broad, narrow-lanceolate, narrowed into a long acuminate point, obliquely cuneate at the base, the upper edge rounded or auricled, the lower edge excised, deeply lobed or pinnatifid, sometimes more than half-way down to the midrib, lobes sharply incised. Veins distinct, close, oblique, forked. Sori shorter than in *A. adiantoides*, in an oblique row close to the midrib of the pinnae, not nearly reaching the margin.—*Hook. Sp. Fil.* iii (1860) 152; *Hook. f. Handb. N.Z. Fl.* (1864) 372; *Hook. and Bak. Syn. Fil.* (1873) 209; *Thoms. N.Z. Ferns* (1882) 75; *Field N.Z. Ferns* (1890) 118; *Cheesem. Man. N.Z. Fl.* (1906) 989.

Kermadec Islands: Sunday Island, not uncommon, *McGillivray, T. F. C., W. R. B. Oliver!*

A widely spread plant, found in most tropical regions. Doubtfully distinct from *A. adiantoides*, from which it chiefly differs in the narrower and more caudate pinnae and shorter sori.

5. **A. obtusatum** *Forst. f. Prodr.* (1786) n. 430.—Rhizome short, thick, often forming a hard rounded mass, densely clothed with large brown shining ovate-lanceolate scales. Stipes 2–6 in. long, erect, very stout, almost fleshy, greyish-green, densely scaly at the base. Fronds 2–12 in. long without the stipes, 1–3 in. broad, linear-oblong, acute, very thick and coriaceous or almost cartilaginous, glabrous or slightly paleaceous when young, pinnate; rhachis broad, often margined, channelled above. Pinnae 6–20 pairs, close-set, often overlapping, shortly stipitate, ¾–1½ in. long, ⅓–¾ in. broad, oblong or linear-oblong, obtuse and rounded at the apex, the terminal pinna alone acute, obliquely truncate-cuneate at the base; margins thick and cartilaginous, crenate-serrate. Veins obscure, simple or forked. Sori oblique to the midrib, usually copious, short, linear-oblong or linear, not reaching the margin.—*A. Cunn. Precur.* (1836) n. 191; *Raoul Choix* (1846) 37; *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 1, f. B, *small specimen; Hook. Sp. Fil.* iii (1860) 96; *Hook. f. Fl. Nov. Zel.* ii (1855) 33; *Handb. N.Z. Fl.* (1864) 371; *Hook. and Bak. Syn. Fil.* (1873) 207; *Benth. Fl. Austral.* vii (1878) 747; *Thoms. N.Z. Ferns* (1882) 73; *Field N.Z. Ferns* (1890) 118, *excl. all varieties quoted; Cheesem. Man. N.Z. Fl.* (1906) 990.

Kermadec Islands: Abundant on maritime rocks, *McGillivray, T. F. C., Miss Shakespear!* North and South Islands: On maritime rocks and outlying islands from the Three Kings Islands and the North Cape to Foveaux Strait, but often local or absent from wide stretches of the coast. Chatham Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island: Apparently not uncommon near the sea.

A. obtusatum is here restricted to Forster's original plant, which appears to be purely littoral. It has a wide range outside New Zealand, being found in Australia and Tasmania, several of the Pacific islands, Juan Fernandez, the coasts of extra-tropical South America, Tristan d'Acunha, and Possession Island.

6. **A. lucidum** *Forst. f. Prodr.* (1786) n. 427.—Rhizome short, stout, often forming a hard and woody rounded caudex, clothed at the top with large brown shining ovate-acuminate scales. Stipes 6–18 in. long,

stout, terete or compressed, densely scaly at the base. Fronds 1–3 ft. long without the stipes, 6–14 in. broad, erect or pendulous, lanceolate to ovate-lanceolate or oblong-lanceolate, acuminate, dark-green and glossy, herbaceous or subcoriaceous, glabrous or slightly paleaceous beneath, pinnate ; rhachis terete or compressed. Pinnae 6–20 pairs, remote or rather close, stipitate, 2–6 in. long, $\frac{3}{4}$–2 in. broad, lanceolate to oblong-lanceolate or elliptic-ovate, usually narrowed into a long acuminate point, often caudate, obliquely cuneate at the base, the upper edge rounded, the lower cut away ; margins somewhat thickened, sinuate-serrate ; veins usually evident, forked. Sori oblique to the midrib, very numerous, close, linear-elongate.—*A. Cunn. Precur.* (1836) n. 189 ; *Raoul Choix* (1846) 37 ; *Hook. Sp. Fil.* iii (1860) 98 ; *Hook. f. Fl. Nov. Zel.* ii (1855) 33 ; *Handb. N.Z. Fl.* (1864) 371 ; *Cheesem. Man. N.Z. Fl.* (1906) 990. A. obtusatum *var.* lucidum *Hook. and Bak. Syn. Fil.* (1873) 207 ; *Benth. Fl. Austral.* vii (1878) 747 ; *Thoms. N.Z. Ferns* (1882) 74 ; *Field N.Z. Ferns* (1890) 119, t. 13, f. 6.

Var. **obliquum** *Moore Ind. Fil.* (1859) 142.—Fronds smaller and more coriaceous, 12–18 in. long. Pinnae more closely placed, 1–3 in. long, oblong-lanceolate, acute but not acuminate. Sori shorter. Approaches *A. obtusatum.*—*A.* obliquum *Forst. f. Prodr.* (1786) n. 429. A. apice-dentatum *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 1A, *and* A. obtusatum t. 1B (*large specimen*). A. obtusatum *var.* obliquum *Hook f. Fl. Antarct.* i (1844) 108 ; *Fl. Nov. Zel.* ii (1855) 33 ; *Handb. N.Z. Fl.* (1864) 371 ; *Hook. Sp. Fil.* iii (1860) 96 ; *Hook. and Bak. Syn. Fil.* (1873) 207.

Var. **Lyallii** *Hook. f. Fl. Nov. Zel.* ii (1855) 33, t. 77.—Size and habit of the type ; but the inferior pinnae lanceolate-deltoid, cut down to the rhachis in the lower part into distinctly stipitate pinnules ; intermediate pinnae more or less deeply lobed, especially on the upper margin, lobes crenate.—*Handb. N.Z. Fl.* (1864) 371 ; *Hook Sp. Fil.* iii (1860) 99. A. Lyallii *Moore Ind. Fil.* (1859) 143.

Kermadec Islands, North and South Islands, Chatham Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island : The typical form widely distributed in lowland districts as far south as Stewart Island. Var. *obliquum* from the North Cape to Campbell Island. Var. *Lyallii :* In various localities from Mangonui (*H. Carse !*) and the Bay of Islands (*Miss Clarke !*) to Otago, but rare and local, and always in small quantity. Chatham Islands, *Field, Miss Seddon !*

In the "Synopsis Filicum" *A. lucidum*, together with *A. obliquum*, was reduced to the position of a variety of *A. obtusatum*. This view was accepted by many pteridologists, mainly, I presume, on account of the undoubted fact that the three plants are more or less connected by transitional forms. But *A. scleropium* also connects *A. lucidum* with *A. flaccidum*, while var. *Lyallii* offers a passage to *A. bulbiferum*, so that by parity of reasoning these species should also be included. This reduction was actually proposed by the late Baron Mueller in his Chatham Island Florula (p. 66), but has found no followers. As arbitrary distinctions must in any case be employed, and as the differences between the typical *A. lucidum* and *A. obtusatum* are quite as well marked as those between several species of *Asplenium* universally admitted, I retained both species in the first edition of this work. Since then further consideration and the examination of extensive suites of specimens have still further strengthened this view ; and I am now of opinion that *A. scleropium* should also be restored to specific rank, as well as Colenso's *A. anomodum*. *A. obliquum* has generally been placed with *A. obtusatum ;* but its position is really a matter of taste ; and it seems to fall more naturally under *A. lucidum*.

A. lucidum has been recorded from Norfolk Island and Lord Howe Island. But it is not enumerated in the recent lists of Laing and Oliver, and its occurrence may therefore be doubted.

7. **A. scleroprium** *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 1D. —Rhizome short, thick, densely covered with dark-brown scales. Stipes 4–8 in. long, broad, flattened or furrowed in front. Fronds 1–1½ ft. high, 5–10 in. broad, linear-lanceolate to oblong-lanceolate, very fleshy and

coriaceous, bright shining-green, pinnate. Pinnae 8–15 pairs, rather closely placed, petiolate, 3–5 in. long, $\frac{1}{2}$–$\frac{3}{4}$ in. broad, narrow-lanceolate, obliquely cuneate at the base, caudate-acuminate at the tip, closely and deeply serrate or pinnatifid. Segments linear or linear-oblong, entire or sometimes bifid at the tip. Sori linear, often extending into the segments, much nearer the margin than the costa. Indusium broad, rigid.—*Hook. f. Fl. Antarct.* i (1844) 109; *Handb. N.Z. Fl.* (1864) 371; *Hook. Sp. Fil.* iii (1860) 97. A. flaccidum *var.* aucklandicum *Hook. f. Fl. Antarct.* i (1844) 109. A. lucidum *var.* scleroprium *Moore Ind. Fl.* (1857–62) 142; *Cheesem. Man. N.Z. Fl.* (1906) 991.

Stewart Island: Not common. Paterson Inlet, Port Pegasus, Wilson Bay, *Cockayne;* Herekopere Island, *T. Kirk!* Small islands off Stewart Island, *Poppelwell.* Auckland Islands: Abundant on the margin of woods near the sea, *Hooker! and many others.*

In the first edition of this work I treated *A. scleroprium* as a transition from *A. lucidum* into *A. flaccidum*, and no doubt there is much to be said for this view. But its usual appearance is so distinct from both *A. flaccidum* and *A. lucidum* that I now consider the better course is to treat it as a separate species.

8. **A. anomodum** *Col. in Trans. N.Z. Inst.* xv (1882) 309.—Rhizome short and stout, globose or ovoid, 1 in. in diam., densely clothed with lanceolate or ovate-lanceolate shining and reticulate blackish-brown scales. Stipes 1$\frac{1}{2}$–6 in. long, sparingly paleaceous. Fronds 1$\frac{1}{2}$–10 in. long without the stipes, 1–4 in. broad, ovate-lanceolate to oblong-lanceolate or oblong, pale greyish-green, subcoriaceous, slightly paleaceous beneath, in small specimens pinnate, in larger bipinnatifid. Pinnae 4–8 pairs with a terminal one, very variable in size and shape, in small specimens $\frac{3}{4}$–1 in. long, oblong, obtuse, crenate or slightly lobed; in larger ones 2–5 in. long, lanceolate or ovate-lanceolate, petiolate, acute or acuminate, deeply lobed or pinnatifid at the base, crenate or serrate above; veins evident, forked. Sori short, linear-oblong to narrow-linear, inclined to the costa of the pinna. Indusium pale whitish-green, thin and membranous.—A. lucidum *var.* anomodum *Cheesem. Man. N.Z. Fl.* (1906) 991.

North and South Islands: Usually in limestone districts. Hawke's Bay—Petane, *A. Hamilton!* Te Aute, *C. P. Winkelmann!* Norsewood, *Colenso!* Takapau, *J. Stewart.* Nelson—Wangapeka Valley and Mount Arthur Plateau, ascending to nearly 4000 ft., *T. F. C.*

If *A. Hookerianum* is to be separated from *A. bulbiferum*, and *A. Richardi* from *A. flaccidum*, then the rank of a species should not be refused to this curious little plant. Although allied to *A. lucidum* var. *Lyallii*, it is quite distinct in the size, shape, and cutting of the frond.

9. **A. Hookerianum** *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 169.—Rhizome short, stout, rounded, emitting numerous fibrous roots, clothed at the top with subulate-lanceolate brownish scales. Stipes 1–4 in. long or more, greenish or greenish-grey, more or less clothed with deciduous scales, becoming almost glabrous when old. Fronds tufted at the top of the rhizome, spreading, 2–10 in. long without the stipes, 1–4 in. broad, oblong-lanceolate to broadly ovate or ovate-deltoid, acuminate, dark-green, herbaceous or almost membranous, pinnate or bipinnate; rhachis and under-surface more or less scaly. Pinnae 4–12 pairs, the largest 1–3 in. long, distinctly stipitate, pinnate, or in small specimens pinnatifid or deeply lobed. Pinnules rather remote, on long slender petioles, usually rounded or rhomboid with a cuneate base, more rarely narrower and

cuneate-oblong, irregularly toothed or lobed or even pinnatifid, rarely again pinnate. Veins subflabellate, forked. Sori 2–5 on a pinnule, short, oblong, remote from the margin.—*Hook. Sp. Fil.* iii (1860) 194; *Moore Ind. Fil.* (1858) 136; *Hook. f. Handb. N.Z. Fl.* (1864) 372; *Hook. and Bak. Syn. Fil.* (1873) 214; *Benth. Fl. Austral* vii (1878) 747; *Thoms. N.Z. Ferns* (1882) 75; *Field N.Z. Ferns* (1890) 120, t. 16, f. 4A; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 243. A. adiantoides *Raoul Choix* (1846) 10, t. 1 (*not of Raddi*). A. adiantoides *var.* Hookerianum *Hook. f. Fl. Nov. Zel.* ii (1855) 35. A. Raouli *Mett. Aspl.* (1859) 118. A. ornatum *Col. in Trans. N.Z. Inst.* xxii (1890) 452.

Var. **Colensoi** *Moore Ind. Fil.* (1858) 137.—Fronds pale-green, usually flaccid. Pinnules on shorter stalks, deeply and finely pinnatifid; segments linear, each with a single vein. Sori oblong, solitary on the margin of the segments.—*Hook. f. Handb. N.Z. Fl.* (1864) 373; *Thoms. N.Z. Ferns* (1882) 75; *Field N.Z. Ferns* (1890) 120, t. 27, f. 1. A. Colensoi *Hook. f. in Lond. Journ. Bot.* iii (1844) 26; *Hook. and Bak. Syn. Fil.* (1873) 219. A. adiantoides *var.* Colensoi *Hook. f. Ic. Plant.* t. 984; *Fl. Nov. Zel.* ii (1855) 35. A. Richardi *var.* Colensoi *Hook. Sp. Fil.* iii (1860) 197.

North and South Islands: From Mangonui and Kaitaia to the south of Otago, but often local. Sea-level to 2500 ft.

A variable little plant, said to be found also in New South Wales and Victoria, but I have seen no specimens from thence. Var. *Colensoi* was placed with *A. Richardi* by Sir W. J. Hooker, and is retained as a distinct species by Mr. Baker in the "Synopsis Filicum." But, as stated by Mr. Field (N.Z. Ferns, 120), it often grows intermixed with the type, and occasionally the fronds of both forms can be found on the same plant. Mr. Colenso's *A. ornatum* is simply a state with the pinnules rather narrower than usual, and on longer stalks.

10. **A. bulbiferum** *Forst. f. Prodr.* (1786) n. 433.—Rhizome short, stout, erect or oblique, crowned with linear-subulate scales. Stipes 4–12 in. long or more, compressed or semiterete, usually dark-brown and densely scaly at the base, above green or greyish-green and either naked or deciduously scaly. Fronds 1–4 ft. long, 6–12 in. broad, ovate-lanceolate or oblong-lanceolate, acuminate, bright-green, scarcely membranous but flaccid, 2–3-pinnate or in small specimens pinnate; rhachis compressed, often scaly when young. Primary pinnae numerous, horizontal, 3–6 in. long, 1–1½ in. broad, lanceolate or ovate-lanceolate, acuminate, often proliferous on the upper surface, cut down to a narrowly winged rhachis into numerous secondary divisions or pinnules. Pinnules ½–1½ in. long, lanceolate to ovate-oblong, deeply pinnatifid; ultimate segments linear-oblong, entire or toothed. Sori short, oblique, oblong, on the disc of the shortly lobed pinnules, but often marginal on the segments of the more deeply divided ones.—*A. Rich. Fl. Nouv. Zel.* (1832) 75; *A. Cunn. Precur.* (1836) n. 193; *Raoul Choix* (1846) 38; *Hook. Ic. Plant.* t. 423; *Sp. Fil.* iii (1860) 196; *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 3, f. 1; *Hook. f. Fl. Nov. Zel.* ii (1855) 34; *Handb. N.Z. Fl.* (1864) 373; *Hook. and Bak. Syn. Fil.* (1873) 218; *Benth. Fl. Austral.* vii (1878) 748; *Thoms. N.Z. Ferns* (1882) 75; *Field N.Z. Ferns* (1890) 121, t. 6, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 993.

Var. **laxum** *Hook. f. Fl. Nov. Zel.* ii (1855) 34.—Fronds smaller and more slender, with narrower and more remote pinnae. Pinnules more deeply divided; segments narrow-linear. Sori often marginal.—*Handb. N.Z. Fl.* (1864) 373; *Hook. Sp. Fil.* iii (1860) 196; *Hook. and Bak. Syn. Fil.* (1873) 218. A. laxum *R. Br. Prodr.* (1810) 151; *Homb et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 3, f. 3. A. gracillimum *Col. in Trans. N.Z. Inst.* xxii (1890) 453. (?) A. triste *Raoul Choix* (1846) 10.

Var. **tripinnatum** *Hook. f. Fl. Nov. Zel.* ii (1855) 34.—Fronds ample, tripinnate, with narrow pinnules and segments resembling some forms of *A. flaccidum*, but more compound and texture thinner. Sori marginal on the segments.—*Handb. N.Z. Fl.* (1864) 373; *Hook. Sp. Fil.* iii (1860) 196. A. tremulum *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt*, t. 3, bis.

North and South Islands, Chatham Islands, Stewart Island, Antipodes Island: Abundant throughout, especially in damp woods. Sea-level to 3000 ft. *Moku.*

The typical state of *A. bulbiferum* is a well-known plant throughout the whole of New Zealand, and is at once distinguished from the other species of the genus by the ample dark-green bipinnate fronds with comparatively broad pinnules, and especially by its habit of producing small bulbils on the upper surface of the frond, which develop into young plants while still attached to the frond. When the bulbils are not developed, and the frond is more slender, with narrower and more deeply divided pinnules, so that the sori are often almost marginal, the plant becomes var. *laxum*. This runs into several small states not clearly separable, one of which is the *A. triste* of Raoul, and another Colenso's *A. gracillimum*. Var. *tripinnatum* has still narrower pinnules, deeply cut into narrow-linear segments, and the sori are quite marginal. It approaches very close to some states of *A. flaccidum*, but the frond is broader and more decompound, and the texture is thinner. In addition to the above varieties there are a large number of puzzling forms, which apparently connect the species with *A. falcatum*, *A. lucidum* var. *Lyallii*, *A. scleroprium*, *A. Hookerianum*, *A. Richardi*, and *A. flaccidum*. In Stewart Island, passage forms into *A. scleroprium* and *A. flaccidum* are particularly abundant, and it is often difficult to decide to which species they should be referred. It would occupy many pages to characterize these, and I doubt whether it is possible to define them in language sufficiently precise to enable them to be recognized with certainty.

A. bulbiferum in some of its forms is also found in Australia and Tasmania, many of the Pacific islands, Malaya, and North India.

11. **A. Richardi** *Hook. f. Fl. Nov. Zel.* ii (1855) 35.—Rhizome short, stout, usually forming a rounded knot-like caudex, clothed at the top with dark-brown subulate scales. Stipes tufted at the top of the rhizome, 2–6 in. long, stout, rigid, erect, greenish, usually clothed with linear scales, rarely almost glabrous. Fronds 3–9 in. long without the stipes, 1–4 in. broad, ovate or ovate-lanceolate, acuminate, dark-green, varying from almost membranous to coriaceous, somewhat rigid, 2–3-pinnate; rhachis smooth or bristly. Primary pinnae 8–12 pairs, rather close, stipitate, $\frac{1}{2}$–2 in. long, ovate-lanceolate to ovate; secondary crowded, often overlapping, ovate-rhomboid, pinnatifid or again pinnate. Ultimate segments $\frac{1}{12}$–$\frac{1}{8}$ in. long, narrow-linear, obtuse or acute or mucronate, each with a single vein. Sori short, broad, oblong, on the margins of the segments.—*Handb. N.Z. Fl.* (1864) 373; *Hook. Sp. Fil.* iii (1860) 197, *excl. var.* Colensoi; *Hook. and Bak. Syn. Fil.* (1873) 222; *Thoms. N.Z. Ferns* (1882) 76; *Field N.Z. Ferns* (1890) 124, t. 28, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 994. A. adiantoides *var.* Richardi *Hook. f. Ic. Plant.* t. 977. A. Raoulii *var.* Richardi *Mett. Aspl.* (1859) 118. A. symmetricum *Col. in Trans. N.Z. Inst.* xxxi (1899) 254.

North Island: Slopes of Ruapehu, *W. Townson!* Tararua Range, *Buchanan, H. C. Field.* South Island: Not uncommon in hilly and mountainous districts throughout. Sea-level to 4000 ft.

A very puzzling plant. Small states with membranous fronds appear to pass directly into *A. Hookerianum* var. *Colensoi*, while larger and more coriaceous forms only differ from erect states of *A. flaccidum* in the more finely cut fronds and smaller segments.

12. **A. flaccidum** *Forst. f. Prodr.* (1786) n. 426.—Rhizome short, stout, erect, clothed at the top with copious dark-brown subulate-lanceolate scales. Stipites tufted at the top of the rhizome, usually rather short,

compressed or angled, greenish, scaly at the base, naked above. Fronds very variable in size and shape, 3 in. to 3 ft. long or more, 2–9 in. broad, the long-fronded varieties lanceolate or oblong-lanceolate, the shorter ones ovate or broadly ovate, acuminate, thick and coriaceous, flaccid and pendulous or rigid and erect, pale-green, quite glabrous, pinnate or bipinnate. Pinnae remote or rather close, 2–10 in. long, $\frac{1}{4}$–$\frac{3}{4}$ in. broad, in the pendulous varieties narrow-linear to lanceolate, but in the small erect forms often much broader, acuminate or caudate, usually cut down to a narrowly winged rhachis into erecto-patent straight or incurved linear-oblong obtuse or acute lobes $\frac{1}{4}$–$\frac{2}{3}$ in. long; or more rarely the pinnae are again pinnate at the base, with the secondary divisions lobed or pinnatifid. Veins indistinct, a single one to each lobe. Sori oblong, usually on the margins of the lobes, rarely on the disc of the pinnae.—*Hook. Sp. Fil.* iii (1860) 205; *Hook. f. Fl. Nov. Zel.* ii (1855) 35; *Handb. N.Z. Fl.* (1864) 374; *Hook. and Bak. Syn. Fil.* (1873) 223; *Benth. Fl. Austral.* vii (1878) 749; *Thoms. N.Z. Ferns* (1882) 76; *Field N.Z. Ferns* (1890) 123, t. 12, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 994. A. heterophyllum *A. Rich. Fl. Nouv. Zel.* (1832) 74. Coenopteris flaccidum *Thunb. Nov. Act. Petr.* ix (1795) 158, t. D., f. 1, 2; *A. Cunn. Precur.* (1836) n. 194; *Raoul Choix* (1846) 38. C. novae-zealandiae *Spreng. in Schrad. Journ.* (1799) 269; *Raoul Choix* (1846) 38. Darea flaccida *Willd. Sp. Plant.* v (1810) 295.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Abundant throughout. Sea-level to 3500 ft.

Also found in Australia and Tasmania, in several of the Pacific islands, and said to have been gathered in South Africa. In New Zealand it varies excessively, the varieties depending to a large extent on the nature of their habitat, specimens growing on trees in damp forests being long and narrow and pendulous, while those found on exposed rocks are broad, rigid, and erect. Sir J. D. Hooker makes 5 varieties in the Handbook, but they are so intimately connected by intermediate forms that it is difficult to provide them with satisfactory definitions.

13. **A. Shuttleworthianum** *Kunze Farrnkr.* i (1840) 26, t. 14.—Rhizome short, tufted. Fronds very variable in size, 1–3 ft. including the stipes, erect or pendulous, broadly ovate or ovate-oblong, acuminate, 3–4-pinnate, glabrous, coriaceous, yellowish-green; inferior pinnae subopposite, somewhat remote; superior alternate, more closely placed, all narrowed into acuminate points; secondary pinnae lanceolate, pinnatifid or again pinnate; ultimate segments very narrow, expanded at the tip to support the sorus, and thus becoming linear-spathulate. Sori copious, very small, mostly solitary and marginal on the segments.—*Mett. Aspl.* (1859) 109; *Hook. Sp. Fil.* iii (1860) 211; *Moore Ind. Fil.* (1860) 168. A. flaccidum *var.* Shuttleworthianum *Hook. f. Handb. N.Z. Fl.* (1864) 374; *Cheesem. Man. N.Z. Fl.* (1906) 995.

Kermadec Islands: Sunday Island, not uncommon on coastal and inland rocks, *McGillivray, T. F. C., Oliver!*

A very handsome and conspicuous species, quite unlike any form of *A. flaccidum*, to which it was reduced by Sir J. D. Hooker. It was discovered on Pitcairn Island by Mr. Cuming, but has since been found in the Samoan Group and elsewhere in Polynesia.

19. **BLECHNUM** Linn.

(Subgenus **Lomaria** Willd.)

Rhizome creeping or short and suberect, sometimes lengthened into a short caudex, rarely long and climbing. Fronds variable in size, usually

simply pinnate or pinnatifid, rarely undivided, very rarely bipinnate, dimorphic; the outer fronds sterile with large and broad flat pinnae, the inner fertile with smaller linear pinnae. Veins free, not anastomosing. Sori linear, in a continuous elongated line occupying the whole space between the midrib and the margin. Indusium linear, membranous, composed of the more or less modified edge of the frond, at first revolute over the sorus, ultimately spreading. Sporangia stalked, girt by an incomplete vertical ring, bursting transversely.

The above description is that of *Lomaria*, the group to which the New Zealand species belong. But *Blechnum* and *Lomaria* only differ from one another in the fact that in *Blechnum* there is an evident interspace between the margin of the frond and the sori, whereas in *Lomaria* there is no such interspace, the sori occupying the whole space between the midrib and the margin. This difference is now not considered to be of generic importance; and pteridologists have transferred the whole of the *Lomariae* to *Blechnum;* a course which I have adopted in this work.

A large group of nearly 50 species, most abundant in the South Temperate Zone, but with outlying species in most temperate and tropical countries. Of the 14 species found in New Zealand, 4 or perhaps 5 are endemic, 2 are widely distributed in the South Temperate Zone, the remainder are found either in Australia or the Pacific islands, or in both.

A. Fronds pinnate or pinnatifid, rarely simple.

* Sterile fronds pinnatifid (or rarely simple), central and lower pinnae connected by their dilated bases.

Fronds 1–3 ft. long, often pendulous, broad, coriaceous, sometimes simple. Pinnae few, large, 4–12 in. long, 1–1½ in. broad .. 1. *B. Patersoni.*

Fronds 1–4 ft. high, narrow, erect. Pinnae very numerous, 1–3 in. × ¼–½ in., reddish or dirty-white beneath .. .. 2. *B. discolor.*

** Sterile fronds pinnatifid above, pinnate below, central and lower pinnae free, but more or less dilated at their bases.

a. Pinnae at the base of the frond not reduced in size.

Fronds 4–14 in., lanceolate-deltoid. Pinnae 1–3 in., lanceolate or ensiform, the lowest pair often deflexed .. .. .. 3. *B. vulcanicum.*

b. Pinnae gradually reduced in size towards the base of the frond.

Fronds 1–3 ft. × 3–6 in., submembranous. Pinnae 1½–3 in. × ⅓–⅔ in., lanceolate, falcate, acuminate. Pinnae of fertile fronds 2–3 in. long .. .. 4. *B. Norfolkianum.*

Fronds 6–18 in. × 2–4 in., submembranous. Pinnae 1–2 in. × ¼–½ in., oblong-lanceolate, obtuse or acute, sinuate-crenate. Pinnae of fertile fronds ¾–1½ in., narrow-linear, acute .. 5. *B. lanceolatum.*

Fronds 9–30 in. × 1½–4 in., fleshy or coriaceous. Pinnae ¾–2½ in. × ¼–½ in., linear-oblong to lanceolate, entire. Pinnae of fertile fronds ¾–1½ in., linear-oblong, obtuse .. .. .. 6. *B. durum.*

Rhizome short. Fronds 4–12 in. × ½–1 in., dark-green, coriaceous. Pinnae ⅓–½ in. × ¼ in., oblong to suborbicular. Fertile fronds shorter than the sterile .. .. 7. *B. Banksii.*

Rhizome creeping. Fronds 2–12 in. × ⅓–⅔ in., coriaceous to submembranous. Pinnae ⅕–⅓ in., ovate-oblong to linear-oblong. Fertile fronds longer than the sterile; pinnae linear-oblong, obtuse .. .. 8. *B. penna-marina.*

*** Sterile fronds pinnate, or pinnatifid above; pinnae not dilated at their bases.

Rhizome short, thick. Fronds often very large, 1–8 ft. long. Pinnae 3–12 in. × ½–1 in., linear, coriaceous .. .. 9. *B. capense.*

Rhizome very long, climbing. Sterile fronds dimorphic; lower with small rounded pinnae; upper with long lanceolate falcate ones .. .. 10. *B. filiforme.*

Rhizome short, suberect. Fronds 3–8 in. × 1–1½ in., blackish-green, lyrate-pinnatifid. Terminal pinnae much longer than the lateral .. .. 11. *B. nigrum.*

Rhizome stout, suberect. Fronds 12–30 in. × ¾–1½ in., linear, membranous; rhachis and stipes bristly and scaly. Pinnae ½–¾ in. × ¼–⅓ in., oblong to suborbicular, obtuse .. .. 12. *B. fluviatile.*

Rhizome short, suberect. Fronds 3–10 in. × ¾–1½ in., submembranous; stipes and rhachis naked. Pinnae ½–¾ in., ovate-oblong to oblong, obtuse .. .. 13. *B. membranaceum.*

B. Fronds bipinnate.

Rhizome often produced into a caudex resembling the trunk of a miniature tree-fern. Fronds 9–18 in. long, ovate, acuminate .. .. 14. *B. Fraseri.*

1. **B. Patersoni** *Mett. Fil. Lips.* (1856) 64; *var.* elongata *Hook. and Bak. Syn. Fil.* (1873) 174.—Rhizome short, stout, creeping, clothed with blackish-brown scales, sometimes stoloniferous; rootlets tomentose. Stipes 3–9 in. long, stout, black, scaly at the base. Sterile fronds very variable; of young plants (and occasionally of old ones) quite simple and entire, 6–12 in. long, 1–1½ in. broad; of old plants pinnatifid, 1–3 ft. long or more, 6–12 in. broad, broadly ovate to ovate-lanceolate, erect or pendulous, coriaceous, glabrous, dark-green above, paler beneath; rhachis winged throughout. Pinnae 4–12 on each side, alternate, acuminate, broadly decurrent at the base, forming a rounded lobe in the sinus, quite entire; at the base of the frond there are usually several small rudimentary pinnae sometimes extending down the stipes almost to its base. Veins numerous, close, free, forked. Fertile fronds as long as the sterile, pinnatifid; pinnae narrow-linear, 4–10 in. long, ⅛–¼ in. broad. Sori continuous, ultimately covering the whole under-surface except the costa.—Lomaria Patersoni *Spreng. Syst. Veg.* iv (1827) 62; *Thoms. N.Z. Ferns* (1882) 64; *Field N.Z. Ferns* (1890) 98, t. 11, f. 3, 3A, 3B; *Cheesem. Man. N.Z. Fl.* (1906) 975. L. elongata *Blume Enum.* (1828) 201; *Hook. Sp. Fil.* iii (1860) 3, t. 143; *Hook. f. Fl. Nov. Zel.* ii (1855) 29; *Handb. N.Z. Fl.* (1864) 367. L. heterophylla *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 175 (*not of Desv.*). L. Colensoi *Hook. f. Ic. Plant.* (1844) t. 627, 628.

North and South Islands, Stewart Island: Damp hilly forests from the Thames and Te Aroha southwards, not common; local on the east side of the South Island. Sea-level to 3000 ft.

The New Zealand variety is also found in the Pacific islands, Malaya, and India. The typical state, which differs in the fronds being usually simple, occurs in Australia, Tasmania, and the Philippines. As in most of the species of the genus, the fronds are sometimes partly fertile and partly sterile.

2. **B. discolor** *Keys. Polyp.* (1873) 66.—Rhizome short, stout, suberect, stoloniferous at the base, often lengthened above into a short erect caudex 1–2 ft. high, clothed at the top with the bases of the old stipites. Stipes 3–6 in. long, stout, polished, densely covered at the base with dark-brown linear scales. Fronds numerous, tufted at the top of the caudex and forming an elegant crown, erect, 1–4 ft. high; sterile linear-lanceolate to oblong-lanceolate, gradually tapering at both ends, 2–6 in. broad in the middle, coriaceous, glossy-green above, dirty-white to reddish-brown beneath, often clothed with rufous scales when young, glabrous when old, deeply pinnatifid or pinnate at the very base. Pinnae very numerous, closely placed, horizontally spreading, 1–3 in. long, ¼–½ in. broad, linear

to linear-oblong, subacute, usually connected by their broad dilated bases, margins minutely sinuate. Veins close, free, forked. Fertile fronds about as long as the sterile but narrower; pinnae ¾–1½ in. long, linear, stout, often flexuous, usually with broad leafy bases. Sori continuous, covering the whole under-surface except the costa. Indusium with the margins much lacerated.—Lomaria discolor *Willd. Sp. Plant.* v (1810) 293; *A. Cunn. Precur.* (1836) n. 181; *Raoul Choix* (1846) 37; *Hook. Sp. Fil.* iii (1860) 5; *Hook. f. Fl. Nov. Zel.* ii (1855) 30; *Handb. N.Z. Fl.* (1864) 368; *Hook. and Bak. Syn. Fil.* (1873) 175; *Benth. Fl. Austral.* vii (1878) 735; *Thoms. N.Z. Ferns* (1882) 65; *Field N.Z. Ferns* (1890) 100, t. 4, f. 2, 2A; *Cheesem. Man. N.Z. Fl.* (1906) 976. Stegania discolor *A. Rich. Fl. Nouv. Zel.* (1832) 87. Onoclea discolor *Swartz Syn. Fil.* (1806) 3. Osmunda discolor *Forst. f. Prodr.* (1786) n. 413.

North and South Islands, Chatham Islands, Stewart Island, Auckland and Campbell Islands: Abundant in open forests throughout. Sea-level to 3000 ft.

Easily distinguished by the tall erect habit, long and narrow horizontally spreading pinnae, and dirty-white or reddish under-surface. The fronds are frequently forked at the top, and a beautiful sport is in cultivation in which the pinnae are greatly expanded in the upper two-thirds of their length, and deeply pinnatifid. Also a native of Norfolk Island, Australia, and Tasmania.

3. **B. vulcanicum** *Kuhn Ann. Lugd. Bat.* iv (1869) 284.—Rhizome short, stout, woody, erect or inclined, densely clothed with the remains of the old stipites. Stipes 4–9 in. long, slender, pale yellow-brown, clothed towards the base with dark-brown shining subulate scales, smooth and polished above. Sterile fronds 4–14 in. long without the stipes, 2–5 in. broad at the base, lanceolate-deltoid, not narrowed below, acuminate, coriaceous, dull-green, glabrous or the surfaces and margins sprinkled with soft white hairs, pinnate at the base, pinnatifid above. Pinnae 1–3 in. long, ¼–⅓ in. broad, spreading, lanceolate or ensiform, broadest at the base, acute or obtuse at the tip, falcate, lowest pair deflexed; margins thickened, entire or minutely crenate-undulate. Veins free, forked. Fertile fronds usually exceeding the sterile and with a longer stipes, pinnate in the lower half; pinnae 1–2 in. long, linear, distant, with a dilated adnate base. Sori continuous; indusium with lacerate margins.—Lomaria vulcanica *Blume Enum.* (1828) 202; *Hook. Ic. Plant.* t. 969; *Sp. Fil.* iii (1860) 12; *Hook. f. Fl. Nov. Zel.* ii (1855) 29; *Handb. N.Z. Fl.* (1864) 367; *Hook. and Bak. Syn. Fil.* (1873) 176; *Benth. Fl. Austral.* vii (1878) 735; *Thoms. N.Z. Ferns* (1882) 65; *Field N.Z. Ferns* (1890) 99, t. 27, f. 5, 5A; *Cheesem. Man. N.Z. Fl.* (1906) 977. L. deltoides *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 177. L. deflexa *Col. l.c.* 178. L. paucijuga *Col. in Trans. N.Z. Inst.* xx (1888) 222.

North and South Islands, Stewart Island: In dry open woods from Auckland and Coromandel southwards, but often rare and local, especially to the north of the East Cape, more frequent in the subalpine forests of Nelson and Canterbury. Sea-level to 3500 ft.

A well-marked species, at once recognized by the narrow-deltoid frond, with the lowest pair of pinnae deflexed. It extends northwards through Australia and the Pacific islands to Malaya.

4. **B. Norfolkianum** *C. Christen. Ind. Fil.* (1905) 157.—Rhizome short, stout, erect or inclined, clothed with the bases of the old stipites mixed with dark-brown chaffy scales. Stipes short, stout, 2–4 in. long, scaly at the

base. Sterile fronds numerous, forming a crown at the top of the rhizome, erect or spreading, 1–3 ft. high, 3–6 in. broad, lanceolate or narrow elliptic-lanceolate, gradually tapering from the middle to both ends, acuminate, dark-green, firm but scarcely coriaceous, quite glabrous, deeply pinnatifid or pinnate at the base. Pinnae numerous, close-set, horizontally spreading, 1½–3 in. long, ⅓–⅔ in. broad, lanceolate, tapering from a broad adnate base to an acuminate point, subfalcate, the lower ones gradually reduced in size to minute auricles, margins crenulate; veins fine, close, forked. Fertile fronds rather shorter than the sterile, pinnate; pinnae remote, very narrow-linear, 2–3 in. long, apiculate.—Lomaria Norfolkiana *Heward in Lond. Journ. Bot.* (1842) 122; *Bak. in Ann. Bot.* v (1891) 219; *Cheesem. Man. N.Z. Fl.* (1906) 977. L. acuminata *Hook. and Bak. Syn. Fil.* (1873) 481; *Thoms. N.Z. Ferns* (1882) 66. L. attenuata *Hook. f. Handb. N.Z. Fl.* (1864) 368; *Field N.Z. Ferns* (1890) 101 (*not of Willd.*).

Kermadec Islands: Sunday Island, abundant, *McGillivray, T. F. C., Oliver!* North Island: Three Kings Islands, *T. F. C.* Little Barrier Island, *Reischek! T. F. C.*

Also in Norfolk Island. It can only be distinguished from *B. lanceolatum* by the greater size, the long acuminate sterile pinnae, and the much longer fertile pinnae, and might well be regarded as a variety only. On both the Three Kings Islands and the Little Barrier it appears to gradually merge into the ordinary state of *B. lanceolatum.*

5. **B. lanceolatum** *Sturm Enum. Pl. Chile* (1858) 25.—Rhizome short, stout, erect or inclined, rarely produced into a short caudex 3–6 in. high. Stipes 2–6 in. long, firm, erect, dark-brown at the base and clothed with subulate scales, paler and glabrous above. Fronds tufted, forming a crown at the top of the rhizome; the sterile ones 6–18 in. long, 2–4 in. broad, lanceolate, acuminate, gradually narrowed to the base, rather membranous, pale-green or dark-green, quite glabrous, pinnate below, pinnatifid above. Pinnae numerous, close-set, horizontally spreading or ascending, 1–2 in. long, ¼–½ in. broad, lanceolate or oblong-lanceolate, attached by a broad somewhat dilated base, gradually tapering to an obtuse or acute point, slightly falcate, usually sinuate-crenate towards the tip, rarely entire; veins conspicuous, free, forked. Fertile fronds usually shorter than the sterile, 1–2 in. broad, pinnate; pinnae ¾–1½ in. long, distant, narrow-linear, acute or apiculate.—Lomaria lanceolata *Spreng. Syst. Veg.* iv (1827) 62; *A. Cunn. Precur.* (1836) n. 180; *Raoul Choix* (1846) 37; *Hook. Ic. Plant.* t. 429; *Sp. Fil.* iii (1860) 11; *Hook. f. Fl. Nov. Zel.* ii (1855) 29; *Handb. N.Z. Fl.* (1864) 367; *Hook. and Bak. Syn. Fil.* (1873) 177; *Benth. Fl. Austral.* vii (1878) 735; *Thoms. N.Z. Ferns* (1882) 66; *Field N.Z. Ferns* (1890) 102, t. 11, f. 2, 2A; *Cheesem. Man. N.Z. Fl.* (1906) 976. L. aggregata *Col. in Trans. N.Z. Inst.* xx (1888) 223; *Field N.Z. Ferns* (1890) 103, t. 29, f. 7, 7A.

North and South Islands, Chatham Islands, Stewart Island: From the North Cape southwards, abundant by the margins of streams, &c. Sea-level to 2500 ft.

Also in Victoria, Tasmania, South Australia, and the Pacific islands. A variable plant. Large specimens pass into *B. Norfolkianum*, and smaller ones are sometimes difficult to separate from *B. membranaceum.*

6. **B. durum** *C. Christen. Ind. Fil.* (1905) 153.—Rhizome stout, erect, clothed with the bases of the old stipites, sometimes lengthened into a short caudex. Stipes 1–2 in. long, clothed at the base with large ovate-

lanceolate brownish scales. Fronds numerous, tufted, forming a crown at the top of the rhizome; sterile 1–2½ ft. long, 1½–4 in. broad, lanceolate, acute or acuminate, usually broadest above the middle, very gradually narrowed to the base, dark-green, fleshy or almost coriaceous, pinnatifid above, pinnate below. Pinnae numerous, close-set, often overlapping, the largest ¾–2½ in. long, ¼–½ in. broad, variable in shape, linear-oblong to lanceolate, obtuse or acute, often falcate, attached by a broad base, the upper narrower and more acute, lowermost dwarfed to rounded auricles; margins entire, slightly thickened. Veins free, forked. Fertile fronds shorter and narrower than the sterile, 1–2½ in. broad; pinnae numerous, close, linear-oblong, rigid, obtuse. Sori very copious, covering the whole under-surface. — Lomaria dura *Moore in Gard. Chron.* (1866) 290; *Hook. f. Handb. N.Z. Fl.* (1864) 748; *Hook and Bak. Syn. Fil.* (1873) 177; *Thoms. N.Z. Ferns* (1882) 66; *Field N.Z. Ferns* (1890) 104, t. 10, f. 4, 4A; *Cheesem. Man. N.Z. Fl.* (1906) 978; *Ill. N.Z. Fl.* ii (1914) t. 240. L. rigida *J. Smith Ferns Brit. and For.* (1866) 290.

South Island: Banks Peninsula, *Armstrong.* Eastern and southern coasts of Otago, not uncommon, *Petrie! Thomson, T. Kirk!* West Coast sounds, *J. D. Enys!* Jackson's Bay and Paringa Bay, Westland, *Cockayne!* Islands in Foveaux Strait, *Poppelwell.* Stewart Island and The Snares: *T. Kirk!* The Solanders: *Cockayne!* Chatham Islands: Abundant, *Chudleigh! Buchanan! Miss Seddon!* Auckland and Campbell Islands, Antipodes Island: *T. Kirk!*

A purely littoral plant, never found far from the influence of sea-spray. Easily recognized by the fleshy or coriaceous habit, the usually obtuse and entire sterile pinnae, and by the close-set broad and rigid fertile pinnae.

7. **B. Banksii** *Mett.; Diels in Pflanzenf.* Teil i, abt. iv (1902) 249.— Rhizome short, stout, woody, erect or inclined, clothed with the old stipites at the top, and with matted fibres below. Stipes short, stout, dark-coloured, furnished at the base with numerous ovate-lanceolate chaffy scales. Fronds numerous; sterile 4–12 in. high, rarely more, ½–1 in. broad, linear-lanceolate, narrowed to both ends, rather coriaceous, dark-green, sometimes with a glaucous tinge, pinnatifid above, pinnate below. Pinnae numerous, close-set, adnate by a broad base, ⅓–½ in. long, rarely more, about ¼ in. broad, broadly oblong or almost semi-orbicular, obtuse, quite entire; lower pinnae much reduced, sometimes forming a sinuated wing down to the base of the stipes. Fertile fronds usually shorter than the sterile, pinnate throughout; pinnae shorter and narrower, more distant, straight or curved. Sori copious, covering the whole under-surface. — Lomaria Banksii *Hook. f. Fl. Nov. Zel.* ii (1855) 31, t. 76; *Handb. N.Z. Fl.* (1864) 368; *Hook. Sp. Fil.* iii (1860) 17; *Hook. and Bak. Syn. Fil.* (1873) 178; *Thoms. N.Z. Ferns* (1882) 67; *Field N.Z. Ferns* (1890) 105, t. 26, f. 2, 2A; *Cheesem. Man. N.Z. Fl.* (1906) 979.

North Island: Auckland—North Cape, *Buchanan;* near Ahipara, *T. F. C., Carse!* Bay of Islands, *A. Cunningham;* Little Barrier Island, *T. Kirk! T. F. C.;* Manukau Heads, *Sinclair, Colonel Haultain!* East Cape, *Colenso!* Taranaki—White Cliffs to Cape Egmont, *Buchanan, T. F. C.* Wellington—Wellington Heads, *Field;* Cape Terawiti, *Kirk!* South Island: Marlborough—Queen Charlotte Sound, *Banks* and *Solander.* Nelson—Cape Farewell, *T. Kirk!* West Wanganui, *Kingsley.* Westland—Jackson's Bay and Paringa, *Cockayne.* Canterbury—Banks Peninsula, *Armstrong.* Otago—Not uncommon on both the East and West Coasts, *Buchanan, Petrie! Thomson, Hamilton!* Stewart Island: Paterson's Inlet, *T. Kirk.*

A well-marked plant, easily recognized by the coriaceous habit and short and broad rounded pinnae attached by a broad base. Like *B. durum*, it is a purely littoral plant, never found beyond the influence of the sea-spray.

8. **B. penna-marina** *Kuhn Fil. Afr.* (1868) 92.—Rhizome long, slender, branched, creeping, clothed with chaffy ferruginous scales. Stipes 2–6 in. long or more, slender, red-brown, smooth and polished, sparingly scaly. Fronds tufted along the rhizome; sterile shorter than the fertile, 4–18 in. long including the stipes, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, often spreading or decumbent, linear or linear-lanceolate, narrowed to the base, dark-green, pinnatifid or pinnate towards the base, texture varying from thick and coriaceous to almost membranous. Pinnae numerous, close-set, short, spreading, $\frac{1}{5}$–$\frac{1}{3}$ in. long, attached by a broad base, ovate-oblong or triangular-oblong to linear-oblong, obtuse, entire or obscurely crenate. Fertile fronds erect, pinnate throughout; pinnae numerous, rather distant, shorter and narrower than the sterile, linear or linear-oblong, obtuse, spreading or deflexed or sometimes curved upwards. Sori copious, covering the whole under-surface.—Lomaria alpina *Spreng. Syst. Veg.* iv (1827) 62; *Hook. Fil. Exot.* (1823–27) t. 32; *Sp. Fil.* iii (1860) 16; *Hook. f. Fl. Antarct.* ii (1844) 393, t. 150; *Fl. Nov. Zel.* ii (1855) 30; *Handb. N.Z. Fl.* (1864) 368; *Hook. and Bak. Syn. Fil.* (1873) 178; *Benth. Fl. Austral.* vii (1878) 736; *Thoms. N.Z. Ferns* (1882) 66; *Field N.Z. Ferns* (1890) 105, t. 17, f. 5, 5A; *Cheesem. Man. N.Z. Fl.* (1906) 980. L. pumila *Raoul Choix* (1846) 9, t. 2A; *Hook. Sp. Fil.* iii (1860) 17; *Hook. f. Fl. Nov. Zel.* ii (1855) 28; *Handb. N.Z. Fl.* (1864) 367. L. linearis *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 176. L. distans *Col. in Trans. N.Z. Inst.* xxviii (1896) 615. L. parvifolia *Col. in Trans. N.Z. Inst.* xx (1888) 224. L. penna-marina *Trev. in Atti. Inst. Ven.* xiv (1869) 570. Stegania alpina *R. Br. Prodr.* (1810) 152. Blechnum alpinum *Metten. Fil. Hort. Bot. Lips.* (1856) 64. Polypodium penna-marina *Poir. Encycl.* v (1804) 520.

North and South Islands, Chatham Islands, Stewart Island, Antipodes Island, Macquarie Island: From the Upper Thames Valley and Rotorua southwards, abundant to the south of the East Cape. Sea-level to 4000 ft.

Also abundant in temperate South America, Australia, and Tasmania. Raoul's *L. pumila* differs from the type in the more membranous fronds and distinctly crenate pinnae, but is without doubt a trivial state produced by growing in an unusually sheltered and shaded locality. Specimens exactly resembling Raoul's plate can be found without any difficulty in both Islands, and can generally be traced on the spot into ordinary *B. penna-marina*. I look upon it as a form too inconstant to keep up even as a variety. *L. parvifolia* Col., of which I possess a type specimen forwarded by Mr. Colenso himself, is clearly the same, a view which is also taken by Mr. Baker (Ann. of Bot. v (1891) 220).

9. **B. capense** *Schlecht. Adumbr.* (1825) 34, t. 18.—Rhizome short, stout, often woody, erect or inclined, sometimes prostrate, clothed at the top with large chestnut-brown scales. Stipes stout, long or short, usually densely scaly at the base. Fronds numerous, very variable in size, usually from 1–4 ft., but in dry exposed places often dwarfed to a few inches, while on the sides of deep wooded ravines they are occasionally 8–10 ft. long or even more; sterile ovate or oblong-ovate to oblong-lanceolate, erect or pendulous, very coriaceous to almost membranous, bright-green to brownish-green, pinnate throughout; rhachis stout, more or less scaly, especially when young. Pinnae often very numerous, but in small specimens and in var. *minor* frequently reduced to 4–6 pairs, alternate, horizontally spreading, 3–12 in. long or more, $\frac{1}{2}$–1 in. broad, acute or acuminate, oblique at the base and cuneate or truncate or rounded-cordate or even auriculate, sessile by the midrib alone or the uppermost more or less adnate; margins minutely toothed; costae more or less scaly.

Veins free, close, parallel, usually forked at the base. Fertile pinnae very narrow-linear, distant, 3–9 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, usually on separate fronds, but often mixed with sterile pinnae or the pinnae partly fertile and partly sterile. Indusium broad, membranous, lacerate.—Lomaria capensis *Willd. Sp. Plant.* v (1810) 291; *F. Muell. Veg. Chat. Is.* (1864) 72; *Benth. Fl. Austral.* vii (1878) 737. L. procera *Spreng. Syst. Veg.* iv (1827) 65; *A. Cunn. Precur.* (1836) n. 182; *Raoul Choix* (1846) 37; *Hook. Ic. Plant.* t. 427–28; *Sp. Fil.* iii (1860) 22; *Garden Ferns*, t. 53; *Hook. f. Fl. Antarct.* i (1844) 110; *Fl. Nov. Zel.* ii (1855) 27; *Handb. N.Z. Fl.* (1864) 366; *Hook. and Bak. Syn. Fil.* (1873) 179; *Thoms. N.Z. Ferns* (1882) 67; *Field N.Z. Ferns* (1890) 107, t. 2, f. 1, 1A; *Cheesem. Man. N.Z. Fl.* (1906) 980. L. latifolia *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 175. L. duplicata *Potts in Trans. N.Z. Inst.* ix (1877) 491. Stegania procera *R. Br. Prodr.* (1810) 153; *A. Rich. Fl. Nouv. Zel.* (1832) 86, t. 13. Osmunda capensis *Linn. Mant.* (1771) 306. O. procera *Forst. f. Prodr.* (1786) n. 414.

Var. **minor** *Hook. f. Fl. Nov. Zel.* ii (1855) 27.—Smaller, 1–3 ft. high, dark olive-green; fertile fronds usually exceeding the sterile. Sterile pinnae few, 4–8 pairs, short, broad, linear-oblong, the lowermost hardly shorter than the one above it, upper often adnate.—Stegania minor *R. Br. Prodr.* (1810) 153.

Kermadec Islands, North and South Islands, Chatham Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island: Abundant throughout, ascending to 4000 ft.

A very widely distributed species. From Australia and Tasmania it extends northwards to Malaya, and is common in many of the Pacific islands. In America it ranges from the south of Chile northwards to Mexico and the West Indies. It is also found in South Africa. In New Zealand it occurs in all soils and situations, and, although attaining its greatest luxuriance in deep forest ravines, is plentiful in open swamps and gullies, and even not averse to bare hillsides or the clefts of rocky peaks. At first it is difficult to believe that the small forms found in exposed places, often not more than 6 in. high, with 3–4 pairs of pinnae, can belong to the same species as the huge specimens growing on moist cliffs in shaded ravines, in which the fronds are sometimes 8–10 ft. long, with more than 40 pairs of pinnae. But every gradation of size exists, and one form can be traced directly into the other. Hooker's var. *minor* is, however, more distinct, and in some respect approaches *Blechnum vulcanicum*. It has a different habit of growth, and possibly should be maintained as a distinct species.

In nearly all the species of *Lomaria* the fertile fronds are sometimes irregularly mixed with sterile pinnae, but in none is this so commonly seen as in *B. capense*. Sometimes one side of the frond may be fertile and the opposite side sterile, or the sterile and fertile pinnae may be irregularly mixed. Or sometimes the upper half of the frond may be fertile and the lower sterile, or *vice versa*. It is also quite common for the pinnae themselves to be partly fertile and partly sterile. The frond is also occasionally once or twice dichotomously forked, constituting Mr. Potts's *Lomaria duplicata*, and sometimes the tips of the fronds are regularly crested.

10. **B. filiforme** *Ettingsh. Denkschr. Ak. Wien* (1864) 21.—Rhizome long, stout, branched, climbing up trees to a great height, clothed with squarrose scales. Sterile fronds very numerous, scattered along the rhizome, pinnate throughout, of two forms; those on the ground or on the lower part of the rhizome small, 3–6 in. long, $\frac{1}{2}$–1 in. broad, linear or linear-lanceolate; pinnae $\frac{1}{4}$–$\frac{1}{2}$ in. long, oblong to orbicular-oblong, sharply and deeply toothed. Fronds from the upper part of the rhizome much larger, 1–$2\frac{1}{2}$ ft. long, 3–6 in. broad, lanceolate, pendulous, hardly coriaceous, dark-green, glabrous or more or less scaly along the rhachis and costae; stipes short, scaly at the base. Pinnae numerous, $1\frac{1}{2}$–4 in. long, about $\frac{1}{2}$ in. broad, lanceolate,

falcate, narrowed upwards into a finely acuminate point, shortly stipitate and truncate or rounded or cordate at the base, margins regularly and finely crenate-dentate. Fertile fronds from near the top of the rhizome, ovate or ovate-oblong in outline; pinnae numerous, 3–6 in. long, $\frac{1}{8}$ in. broad, very narrow-linear or almost filiform. Indusium very narrow.—Lomaria filiformis *A. Cunn. Precur.* (1836) n. 183; *Raoul Choix* (1846) 37; *Hook. Sp. Fil.* iii (1860) 33, t. 149; *Hook. f. Handb. N.Z. Fl.* (1864) 366; *Hook. and Bak. Syn. Fil.* (1873) 180; *Thoms. N.Z. Ferns* (1882) 68; *Field N.Z. Ferns* (1890) 109, t. 10, f. 3, 3A, 3D; *Cheesem. Man. N.Z. Fl.* (1906) 982. L. propinqua *A. Cunn. Precur.* (1836) n. 184. L. pimpinellifolia *Hook. f. in Hook. Lond. Journ. Bot.* iii (1844) 412. Stenochlaena heteromorpha *J. Smith in Hook. Lond. Journ. Bot.* iv (1845) 149; *Hook. f. Fl. Nov. Zel.* ii (1855) 46; *Brack. Bot. U.S. Expl. Exped.* (1854) 77. Osmunda reptans *Forst. f. Prodr.* (1786) n. 93 (*nomen*).

North and South Islands: In forests from the North Cape southwards to Nelson and Marlborough, abundant. Sea-level to 2000 ft.

Also recorded from the Fiji Islands. A most distinct species, remarkable for its very long climbing rhizome and dimorphic sterile fronds.

11. **B. nigrum** *Metten. in Ann. Sci. Nat.* xv (1861) 69.—Rhizome short, stout, suberect, clothed with the bases of the old stipites mixed with chaffy scales. Stipes slender, densely scaly, 1–3 in. long. Sterile fronds tufted at the top of the rhizome, spreading, 3–8 in. long, 1–1½ in. broad, linear-oblong, membranous, blackish-green or lurid-green, brittle when dry, glabrous or the margins and under-surface more or less clothed with short rufous hairs, lyrate-pinnatifid, pinnate at the base; rhachis usually densely pubescent. Pinnae 4–8 pairs, unequal in size; the terminal one much the largest, 1–2 in. long, oblong, obtuse, irregularly lobed or sinuate; the lateral $\frac{1}{4}$–$\frac{3}{4}$ in. long, oblong to orbicular-oblong, irregularly sinuate, the lowest pair larger than those immediately above, and often stipitate and deflexed. Fertile fronds few, erect, pinnate; pinnae few, distant, narrow-linear, apiculate, the terminal one elongated, the lateral much shorter.—Lomaria nigra *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 176; *Hook. Ic. Plant.* t. 960; *Sp. Fil.* iii (1860) 35; *Hook. f. Fl. Nov. Zel.* ii (1855) 31; *Handb. N.Z. Fl.* (1864) 369; *Hook. and Bak. Syn. Fil.* (1873) 181; *Thoms. N.Z. Ferns* (1882) 69; *Field N.Z. Ferns* (1890) 110, t. 25, f. 4, 4A; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 241. Polybotrya nana *Fèe Acrost.* (1845) 75, t. 38, f. 1.

North Island: Dark gloomy forests from Hokianga and Mangonui southwards, not common. South Island: Nelson—Collingwood, *D. Grant;* Takaka and West Wanganui, *Kingsley.* Westland—Abundant at low elevations, *Enys! A. Hamilton! J. W. Brame!* &c. Otago—Milford Sound, Bligh's Sound, *Lyall, Hector* and *Buchanan.* Stewart Island: Rare, *Cockayne!* Sea-level to 3000 ft.

Easily recognized by the enlarged terminal portion of the frond, which is often only shallowly lobed, while the lower pinnae are usually distinct from one another. The surface of the frond is often overgrown with mosses or hepaticae, in the same manner as in *Trichomanes elongatum.*

12. **B. fluviatile** *Salom. Nomencl.* (1883) 115.—Rhizome stout, suberect, often woody, densely clothed with the bases of the old stipites and with chestnut-brown subulate scales. Stipes very short, densely scaly. Sterile fronds very numerous, forming a broad spreading crown at the top of the rhizome, 1–2½ ft. high, $\frac{3}{4}$–1½ in. broad, linear or linear-lanceolate,

submembranous, pale brownish-green, pinnate throughout; rhachis densely clothed with spreading subulate scales. Pinnae very numerous, 20–50 pairs, $\frac{1}{2}$–$\frac{3}{4}$ in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, oblong to orbicular-oblong, obtuse, not decurrent, the lower more remote and often shortly stipitate, the upper sessile, the uppermost usually adnate; margins thin, sinuate or denticulate. Fertile fronds narrow-linear, erect; pinnae $\frac{1}{3}$–$\frac{2}{3}$ in. long, $\frac{1}{8}$ in. broad, linear, obtuse, erecto-patent.—Lomaria fluviatilis *Spreng. Syst. Veg.* iv (1827) 64; *Hook. Sp. Fil.* iii (1860) 34; *Hook. f. Fl. Nov. Zel.* ii (1855) 28; *Fl. Tasm.* ii (1860) 142, t. 167; *Handb. N.Z. Fl.* (1864) 366; *Hook. and Bak. Syn. Fil.* (1873) 181; *Benth. Fl. Austral.* vii (1878) 736; *Thoms. N.Z. Ferns* (1882) 69; *Field N.Z. Ferns* (1890) 109, t. 27, f. 2, 2A; *Cheesem. Man. N.Z. Fl.* (1906) 983. L. rotundifolia *Raoul Choix* (1846) 9, t. 23. L. rotundifolia *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 179. Stegania fluviatilis *R. Br. Prodr.* (1810) 152.

North and South Islands, Chatham Islands, Stewart Island: From Hokianga and Whangaroa southwards, not uncommon in damp hilly forests. Sea-level to 2500 ft.

Also in Victoria and Tasmania. A crested form is occasionally seen, and has been described by Mr. Colenso as var. *ramosa* (Trans. N.Z. Inst. xx (1888) 225).

13. **B. membranaceum** *Metten. Ann. Sci. Nat.* xv (1861) 77.—Rhizome short, stout, suberect, clothed with the bases of the old stipites mixed with a few subulate scales. Stipes very short, scaly at the base. Fronds tufted at the top of the rhizome, the sterile ones 3–10 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, lanceolate or linear-lanceolate, acuminate, broadest above the middle, gradually narrowed to the base, rather membranous, pale-green, quite glabrous, pinnate; rhachis smooth, naked. Pinnae numerous, spreading or erecto-patent, the longest $\frac{1}{2}$–$\frac{3}{4}$ in. long, about $\frac{1}{4}$ in. broad, ovate-oblong or oblong, obtuse, broadly adnate at the base but not dilated nor decurrent, coarsely dentate-serrate, the lower quite distinct at the base, gradually becoming smaller and eventually reduced to mere rounded auricles, the uppermost more or less confluent. Fertile fronds usually longer than the sterile and with longer stipites, pinnate; pinnae distant, $\frac{1}{6}$–$\frac{1}{2}$ in. long, linear, apiculate.—Lomaria membranacea *Col. in Hook. Sp. Fil.* iii (1860) 34, t. 145; *Hook. Handb. N.Z. Fl.* (1864) 366; *Hook. and Bak. Syn. Fil.* (1873) 181; *Thoms. N.Z. Ferns* (1882) 69; *Field N.Z. Ferns* (1890) 111, t. 5, f. 6, 6A; *Cheesem. Man. N.Z. Fl.* (1906) 984. L. oligoneuron *Col. in Trans. N.Z. Inst.* xvi (1884) 346. L. intermedia *Col. l.c.* xix (1887) 274. L. pygmaea *Col. l.c.* xxv (1893) 322.

North Island: Shaded places by the banks of streams, not uncommon throughout. South Island: In various localities along the east coast from Nelson to Otago, but apparently rare and local. Sea-level to 2000 ft.

Large forms of this, with longer and narrower pinnae rather more closely placed, are difficult to distinguish from *B. lanceolatum*, if, indeed, the two species do not pass directly into one another. In its usual state, however, it is a much smaller plant, with shorter and broader obtuse pinnae, distinctly separated from one another, and not dilated at the base or decurrent as in *lanceolatum*. I have seen no specimens from Canterbury or Otago.

14. **B. Fraseri** *Luerss. in Flora* (1876) 292.—Rhizome erect, clothed with the bases of the old stipites and with a dense tuft of dark chestnut-brown scales at the tip, often elongated into a slender caudex 6–24 in. high or more, resembling the trunk of a miniature tree-fern. Stipes 3–9 in.

high, scaly towards the base. Fronds forming a spreading crown at the top of the caudex, 9–18 in. long, 3–6 in. broad, ovate or ovate-oblong to ovate-lanceolate, acuminate, quite glabrous, almost membranous or subcoriaceous, bipinnate; rhachis with a narrow interrupted wing furnished with numerous triangular lobes. Pinnae 2–3 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, lanceolate or linear-lanceolate, acuminate, cut down almost to the rhachis. Pinnules numerous, close-set, $\frac{1}{4}$–$\frac{1}{3}$ in. long, linear-oblong, somewhat falcate, acute or apiculate, entire or serrate. Veins indistinct, simple or forked. Fertile fronds similar to the sterile, but rather smaller and with narrower pinnules. Sori covering the whole under-surface. — Lomaria Fraseri *A. Cunn. Precur.* (1836) n. 185; *Raoul Choix* (1846) 37; *Hook. Ic. Plant.* t. 185; *Sp. Fil.* iii (1860) 40; *Hook. f. Fl. Nov. Zel.* ii (1855) 31; *Handb. N.Z. Fl.* (1864) 369; *Hook. and Bak. Syn. Fil.* (1873) 182; *Thoms. N.Z. Ferns* (1882) 70; *Field N.Z. Ferns* (1890) 111, t. 24, f. 4, 4A; *Cheesem. Man. N.Z. Fl.* (1906) 984; *Ill. N.Z. Fl.* ii (1914) t. 242.

North Island: Abundant in dry woods from the North Cape southwards to the Upper Waikato and Taranaki. South Island: Nelson—Massacre Bay, *Lyall;* West Wanganui, *Kingsley;* extending along the West Coast as far south as Charleston, *T. Kirk.* Sea-level to 2000 ft.

A very handsome and distinct species, quite unlike any other. It has been found in the Philippine Islands, and specimens from thence have been described by Dr. Christ as "var. *philippensis.*" Examples kindly forwarded to me by Dr. Merrill, of Manila, show but little difference from the New Zealand plant, but the caudex is said to attain a height of 6 ft.

20. **DOODIA** R. Br.

Rhizome short, tufted, suberect. Fronds numerous at the top of the rhizome, erect, harsh and rigid or membranous, pinnate or pinnatifid, sometimes dimorphic. Veins forked, connected by short cross veinlets on which the sori are placed. Sori oblong or slightly curved, in one or more rows parallel to the midrib, and between it and the margin of the pinnae. Indusium the same shape as the sorus, attached to the cross veinlet, membranous, opening towards the midrib. Sporangia stalked, surrounded by an incomplete vertical ring, bursting transversely.

A small genus of 5 species, found in New Zealand, Australia and Polynesia, and Ceylon.

Fronds 1–2 ft., harsh, coriaceous, erect; the sterile not obviously differing from the fertile .. .. 1. *D. media.*

Fronds $\frac{1}{2}$–1 ft., submembranous; the sterile shorter and less erect, with broader obtuse pinnae. Fertile pinnae narrow-linear, with conspicuous auricled bases.. .. .. 2. *D. caudata.*

1. **D. media** *R. Br. Prodr.* (1810) 151.—Rhizome short, stout, suberect, clothed with the bases of the old stipites. Stipes 3–8 in. long, more or less clothed with subulate scales towards the base, smooth or scabrous, blackish-brown. Fronds 12–18 in. long, $1\frac{1}{2}$–4 in. broad, lanceolate, acuminate, coriaceous, dark-green, pinnate in the lower half or two-thirds, pinnatifid above; rhachis often pubescent. Pinnae numerous, spreading; lateral 1–2 in. long, $\frac{1}{5}$–$\frac{1}{3}$ in. broad, linear or linear-lanceolate, acute or obtuse, spinulose-dentate, the upper ones dilated and confluent at the base, those below the middle free but often dilated or almost auricled at the base, the lower ones gradually reduced in size; terminal pinna often elongated. Sori short, oblong, usually in one series on each side of the midrib, but sometimes portions of a second row are irregularly developed.—*Hook. Sp.*

Fil. iii (1860) 74; *Hook. f. Handb. N.Z. Fl.* (1864) 370; *Hook. and Bak. Syn. Fil.* (1873) 190; *Thoms. N.Z. Ferns* (1882) 70; *Field N.Z. Ferns* (1890) 112, t. 20, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 985. D. aspera *A. Rich. Fl. Nouv. Zel.* (1832) 76; *A. Cunn. Precur.* (1836) n. 195; *Raoul Choix* (1846) 38 (*not of R. Br.*). D. Kunthiana *Gaud. in Freyc. Voy. Bot.* (1827) 401, t. 14; *A. Cunn. Precur.* (1836) n. 197; *Raoul Choix* (1846) 38.

Var. **Milnei** *Bak. Syn. Fil.* edit. 2 (1873) 482.—Larger; fronds 1–2 ft. long or more, 6–12 in. broad. Pinnae closely placed, $\frac{1}{4}$–$\frac{1}{2}$ in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, narrowed into long acuminate points, sharply dentate-serrate. Sori copious, in 2 rows on each side of the midrib.—D. Milnei *Carr. in Seem. Fl. Viti.* (1873) 352. D. connexa *Hook. f. Handb. N.Z. Fl.* (1864) 369 (*not of Kunze*).

North Island: Abundant from the North Cape to the East Cape, from thence rare and local to Cook Strait. South Island: Nelson—Port Hills, *T. Kirk!* Var. *Milnei.* —Kermadec Islands: Abundant, *McGillivray, T. F. C., Oliver!* Sea-level to 1000 ft.

Also in Australia, Norfolk Island, and the Pacific islands as far north as Hawaii A very variable plant.

2. **D. caudata** *R. Br. Prodr.* (1810) 151.—Rhizome short, suberect, emitting numerous black wiry rootlets. Stipes 2–4 in. long, slender, black, smooth or nearly so. Fronds numerous, densely tufted, 3–12 in. long, rarely more, $\frac{3}{4}$–2 in. broad, lanceolate, acuminate or caudate, usually membranous, pale-green, pinnate almost to the top, more or less dimorphic; sterile usually shorter than the fertile and less erect, often decumbent, sometimes almost flaccid; pinnae oblong or linear-oblong, obtuse, sharply serrate. Fertile fronds longer, usually harsher and more rigid, erect; pinnae $\frac{1}{2}$–$1\frac{1}{2}$ in. long, $\frac{1}{8}$–$\frac{1}{5}$ in. broad, narrow-linear, often attenuate, the lower ones usually conspicuously auricled at the base, the uppermost decurrent and confluent, terminal pinna usually very long, caudate. Sori in a single series on each side of the midrib.—*A. Rich. Fl. Nouv. Zel.* (1832) 76; *A. Cunn. Precur.* (1836) n. 196; *Raoul Choix* (1846) 38; *Hook. f. Fl. Nov. Zel.* ii (1855) 37, *excl. syn.; Hook. and Bak. Syn. Fil.* (1873) 190; *Field N.Z. Ferns* (1890) 114, t. 20, f. 4, 4a; *Cheesem. Man. N.Z. Fl.* (1906) 986. D. squarrosa *Col. in Trans. N.Z. Inst.* xiii (1881) 382.

North Island: From Kaitaia southwards to Cook Strait, but local and often absent from large areas. Sea-level to 2500 ft.

Apparently a common Australian plant, ranging from Cape York to Tasmania. Some of the New Zealand forms approach very close to the preceding species; but usually it can be distinguished by the smaller size, by the sterile fronds being of a different shape and more flaccid than the fertile, and by the narrow fertile pinnae with conspicuously auricled bases. A small variety found on the Rimutaka Range, Wellington, is said to have scented fronds, and to have been formally collected by the Maoris for the purpose of mixing with oil to anoint the person; but I have never been able to preceive any fragrance. Perhaps *Polypodium pustulatum* has been mistaken for it. I have seen no authentic specimens of Colenso's *D. squarrosa*, and have followed Mr. Baker (Ann. Bot. v (1891) 221) in referring it to *D. caudata.*

21. **GYMNOGRAMME** Desv.

Rhizome short and tufted or long and creeping. Fronds very various, small or large, pinnate or 2–3-pinnate, rarely simple. Veins simple or forked, or more or less copiously anastomosing. Sori placed on the veins on the under-surface of the fronds, oblong or linear, often elongated, simple or forked. Indusium not developed. Sporangia stalked, bursting transversely, surrounded by an incomplete vertical ring.

As defined above, this is a heterogeneous assemblage of over 100 species, differing greatly from one another in habit, venation, and the arrangement of the sori, and often split up by authors into several small genera. Under this system *G. rutaefolia* would fall into the genus *Pleurosorus*, while *G. leptophylla*, with a few allied plants, would constitute the genus *Anogramma*. But in a small flora like that of New Zealand it seems inadvisable to encourage the multiplication of closely allied small genera, only separated by comparatively trivial characters.

Perennial. Fronds pinnate or 2-pinnatifid, subcoriaceous, densely clothed with ferruginous woolly hairs .. .. .. 1. *G. rutaefolia.*

Annual. Fronds 2-3-pinnate, thin and membranous, quite glabrous 2. *G. leptophylla.*

1. **G. rutaefolia** *Hook. and Grev. Ic. Fil.* (1829) t. 90.—Rhizome short, thick, erect or ascending, clothed with blackish-brown lanceolate scales. Stipes ¼–1 in. long, stout or slender, everywhere densely villous with soft ferruginous woolly often glandular hairs. Fronds 1–3 in. long by about ½ in. broad, linear-oblong, obtuse, subcoriaceous, pinnate; both surfaces densely clothed with soft ferruginous or silvery-brown woolly hairs, many of which are glandular-tipped. Pinnae alternate, rather distant, ⅛–½ in. long, obovate or rhomboid or flabellate, shortly stipitate and obliquely cuneate at the base, the lowermost with 2–3 shallow lobes or rarely pinnatifid. Veins flabellate. Sori linear-oblong, occupying most of the veins of the under-surface, distinct at first, but often confluent in age.—*Hook. Fil. Exot.* (1857–59) t. 5; *Sp. Fil.* v (1864) 137; *Hook. f. Fl. Nov. Zel.* ii (1855) 45; *Handb. N.Z. Fl.* (1864) 383; *Armstr. in Trans. N.Z. Inst.* xiii (1881) 359. G. Pozoi *var.* rutaefolia *Hook. and Bak. Syn. Fil.* (1873) 379; *Thoms. N.Z. Ferns* (1882) 91; *Field N.Z. Ferns* (1890) 144, t. 10, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1016. G. alpina *Potts in Trans. N.Z. Inst.* x (1878) 361. Grammitis rutaefolia *R. Br. Prodr.* (1810) 146; *Benth. Fl. Austral.* vii (1878) 775. Ceterach rutaefolia *Metten. Fil. Hort. Lips.* (1856) 80. Pleurosorus rutaefolius *Fèe Gen. Fil.* (1850–52) 180.

North Island: Hawke's Bay—Mount Cameron, *F. Hutchinson!* Petane, *A. Hamilton!* Kuripapanga, *H. Hill!* Wellington—Cliffs in Cook Strait, *Colenso!* Cape Terawhiti, *Field.* South Island: Marlborough—D'Urville Island, *E. Craig!* Brothers Islands, *Field.* Canterbury—Banks Peninsula, Upper Ashburton, Upper Rangitata, *T. H. Potts!* Southern Alps, *J. D. Enys!* Otago—Black's, *Petrie.* Sea-level to 3500 ft.

Also widely distributed in Australia and Tasmania. It is united by most authors to the European *G. Pozoi*, which, however, seems to me to differ in the more slender habit, in being much less densely villous, the hairs seldom glandular, and in the narrower oblong (not obovate or flabellate) pinnae.

2. **G. leptophylla** *Desv. Journ. Bot.* i (1813) 26.—Slender, delicate, annual, 1–6 in. high. Roots fibrous. Stipes ½–3 in. long, slender, brittle, smooth, glossy, bright chestnut-brown. Fronds 1–3 in. long, ½–1 in. broad, ovate or ovate-oblong to oblong-lanceolate; the outer spreading, much shorter and broader, usually sterile; the inner longer and narrower, fertile, erect; pale-green, shining, thin and membranous, quite glabrous, 2–3-pinnate. Pinnae alternate, stipitate, ¼–½ in. long, again pinnate; secondary rhachises margined throughout. Pinnules few, obovate-cuneate, 2–3-lobed or -partite; lobes linear or linear-oblong, obtuse. Veins forked, a single veinlet only to each lobe. Sori oblong or linear-oblong, usually a single one to each lobe, often becoming confluent and covering the whole pinnule.—*Hook. and Grev. Ic. Fil.* (1829) t. 25; *Hook. Sp. Fil.* v (1864) 136; *Hook. f. Fl. Nov. Zel.* ii (1855) 45; *Handb. N.Z. Fl.* (1864) 383; *Hook. and Bak. Syn. Fil.* (1873) 383; *Thoms. N.Z. Ferns* (1882) 92; *Field N.Z. Ferns*

(1890) 144, t. 16, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 1016. G. novae-zelandiae *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 165. Grammitis leptophylla *Swartz Syn. Fil.* (1806) 218; *Benth. Fl. Austral.* vii (1878) 776. Anogramme leptophylla *Link Fil. Sp.* (1841) 137.

North Island: Auckland—Volcanic hills on the Auckland Isthmus, once common, now rare and apparently restricted to Mount Wellington and Mount Smart, *Colenso*, &c.; Mount Maunganui (near Tauranga), *Mrs. Hetley!* East Cape district, *Bishop Williams.* Hawke's Bay—Scinde Island, *Colenso!* Ruahine Mountains, *H. Tryon!* Wellington—Miramar, *Buchanan!* South Island: Canterbury—Lyttelton Harbour, abundant, *T. H. Potts!* Otago—Near Dunedin, *Purdie;* Upper Clutha, *Petrie.* Sea-level to 1500 ft.

Also in south Europe, North and South Africa, Persia, India, Australia and Tasmania, and South America.

22. **PELLAEA** Link.

Rhizome usually creeping. Fronds tufted, or scattered along the rhizome, simply pinnate in the New Zealand species, 2–3-pinnate and often palmate or pedate in others; texture subcoriaceous or membranous; veins always free but often obscure. Sori marginal, in an early stage distinct and oblong or linear-oblong, decurrent along the tips of the veins, but soon becoming confluent and forming a continuous broad or narrow marginal band. Indusium formed of the modified edge of the frond, continuous, often very narrow, at first involute over the sori, ultimately spreading, often hidden by the ripe sporangia. Sporangia stalked, with an incomplete vertical ring, bursting transversely.

About 60 species are known, found in the temperate and tropical regions of both hemispheres. One of the two New Zealand species extends as far north as India, the other is said to occur in Australia.

Erect. Pinnae ¾–2 in. long, lanceolate to linear-oblong .. 1. *P. falcata.*

Often decumbent. Pinnae ⅓–¾ in. long, oblong to orbicular .. 2. *P. rotundifolia.*

1. **P. falcata** *Fèe Gen. Fil.* (1850–52) 129.—Rhizome stout, creeping, scaly. Stipes 3–6 in. long, strong, erect, dark red-brown or almost black, more or less hispid with spreading scales. Fronds 12–18 in. long or more, 1½–3 in. broad, linear or linear-oblong, simply pinnate; rhachis densely scaly and bristly. Pinnae 15–40 on a side, quite entire, alternate, shortly petiolate or the upper sessile, ¾–2 in. long, ¼–½ in. broad, lanceolate or oblong-lanceolate to linear-oblong, often slightly falcate, acute or mucronate, truncate or cuneate at the base, the lower ones slightly auriculate on the upper margin near the base; texture coriaceous; both surfaces glabrous or nearly so; veins not visible. Sori usually forming a broad continuous marginal band all round the pinnae. Indusium very narrow, membranous, continuous.—*Hook. Sp. Fil.* ii (1858) 135, t. 111B; *Hook. f. Handb. N.Z. Fl.* (1864) 363; *Hook. and Bak. Syn. Fil.* (1873) 151; *Thoms. N.Z. Ferns* (1882) 58; *Field N.Z. Ferns* (1890) 88, t. 18, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 968. Pteris falcata *R. Br. Prodr.* (1810) 154; *Hook. f. Fl. Nov. Zel.* ii (1855) 24; *Benth. Fl. Austral.* vii (1878) 729. P. seticaulis *Hook. Ic. Plant.* (1840) t. 207. Platyloma falcatum *J. Smith in Journ. Bot.* (1841) 160.

Kermadec Islands: *McGillivray, T. F. C., Oliver!* North Island: Auckland—In various localities from Kaitaia to the Waikato River, but rare and local. South Island: Nelson—Dun Mountain, *Potts;* near Nelson, *D. Grant;* Graham River, *T. F. C.*

Extends to Australia and Tasmania, the Malay Archipelago, and India. All the New Zealand specimens that I have seen have shorter and broader pinnae than the typical state, and approach *P. rotundifolia* so closely as to make it probable that the two species are forms of one plant.

2. **P. rotundifolia** *Hook. Sp. Fil.* ii (1858) 136.—Habit of *P. falcata*, but smaller and more slender, and fronds often decumbent. Rhizome long, rigid, wiry, creeping, clothed with appressed scales. Stipes 3–6 in. long, dark red-brown, densely pubescent and scaly. Fronds 6–14 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, linear, simply pinnate ; rhachis bristly and scaly throughout. Pinnae 10–30 on each side, alternate, petiolate or the upper sessile, quite entire, $\frac{1}{3}$–$\frac{3}{4}$ in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, variable in shape, oblong or oblong-ovate to orbicular, obtuse or mucronate at the tip, rounded or obliquely truncate at the base, glabrous or nearly so, coriaceous ; veins concealed. Sori forming broad marginal lines on both the upper and lower edges of the pinnae, but not so continuous as in *P. falcata*. Indusia very numerous, membranous, involute when young, but soon reflexed and often concealed by the sporangia.—*Hook. Fil. Exot.* (1857–59) t. 48 ; *Hook. f. Handb. N.Z. Fl.* (1864) 363 ; *Hook. and Bak. Syn. Fil.* (1873) 151 ; *Thoms. N.Z. Ferns* (1882) 59 ; *Field N.Z. Ferns* (1890) 89, t. 14, f. 2 ; *Cheesem. Man. N.Z. Fl.* (1906) 969. Pteris rotundifolia *Forst. f. Prodr.* (1786) n. 420 ; *A. Rich. Fl. Nouv. Zel.* (1832) 78 ; *A. Cunn. Precur.* (1836) n. 198 ; *Raoul Choix* (1846) 38 ; *Hook. Ic. Plant.* (1842) t. 422 ; *Benth. Fl. Austral.* vii (1878) 730. Allosurus rotundifolius *Kunze in Linnæa*, xxviii (1850) 219. Platyloma rotundifolium *J. Smith in London Journ. Bot.* (1841) 160.

North and South Islands, Chatham Islands : From the North Cape to Foveaux Strait, not uncommon in dry woods. Sea-level to 2000 ft.

Also in Norfolk Island ; and Bentham refers a Queensland plant to the same species.

23. **NOTHOCHLAENA** R. Br.

Rhizome short and tufted or long and creeping. Fronds usually small, erect, pinnate or 2–3-pinnate ; under-surface more or less densely scaly or woolly or coated with white powder ; texture coriaceous. Veins free, forked, not anastomosing. Sori marginal, oblong or rounded, terminating the veins, at first distinct, but soon confluent into a continuous or interrupted marginal line, often partly concealed by the slightly inflexed margin of the frond, but with no true indusium. Sporangia stalked, bursting transversely, girt by an incomplete vertical ring.

A genus of between 30 and 40 species, widely dispersed through the tropical and warm temperate regions of both hemispheres. It hardly differs from *Cheilanthes*, except in the recurved margin of the frond not being distinctly modified into an indusium. The single New Zealand species is also found in Australia, Norfolk Island, and New Caledonia.

Cheilanthes distans (R.Br.) Copel.

1. **N. distans** *R. Br. Prodr.* (1810) 146.—Rhizome short, stout, suberect or prostrate, clothed with the bases of the old stipites and with ferruginous linear scales. Stipes 1–4 in. long, stiff, wiry, erect, dark chestnut-brown, more or less clothed with subulate-lanceolate scales. Fronds numerous, tufted at the top of the rhizome, 3–6 in. long without the stipes, $\frac{1}{2}$–1 in. broad, linear-oblong, erect, rigid, subcoriaceous,

sparingly villous or hairy above, beneath densely covered with long linear-subulate ferruginous scales, 2-pinnate. Primary pinnae stipitate, opposite or nearly so, the lower remote, $\frac{1}{3}$–$\frac{2}{3}$ in. long, ovate-deltoid, pinnate at the base, pinnatifid above. Pinnules few, seldom more than 2–3 pairs, ovate-oblong, obtuse, the lowest pinnatifid at the base; margins recurved. Sori forming a continuous line round the margin.—*Hook. Ic. Plant.* (1854) t. 980; *Sp. Fil.* v (1864) 114; *Hook. f. Fl. Nov. Zel.* ii (1855) 46; *Handb. N.Z. Fl.* (1864) 383; *Hook. and Bak. Syn. Fil.* (1873) 373; *Benth. Fl. Austral.* vii (1878) 774; *Thoms. N.Z. Ferns* (1882) 91; *Field N.Z. Ferns* (1890) 143, t. 16, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1015. Cheilanthes *n. sp. Field N.Z. Ferns* (1890) 88, t. 28, f. 4.

North Island: Rocky places from the Bay of Islands to Cook Strait, local. South Island: Near Nelson, *T. F. C.* Banks Peninsula and other localities in Canterbury, *Armstrong, T. H. Potts, A. Wall!* Sea-level to 2500 ft.

Often confused with *Cheilanthes Sieberi*, of which it has the habit and general appearance; but a smaller plant, with the frond conspicuously shaggy and scaly beneath.

24. **CHEILANTHES** Swartz.

Rhizome short and tufted, or long and creeping. Fronds usually small, erect, 2–3-pinnate; texture subcoriaceous. Veins free, forked, not anastomosing. Sori marginal, terminating the veins, small, rounded or oblong, at first distinct, afterwards more or less confluent. Indusium roundish or oblong, consisting of a more or less modified tooth or lobule of the frond, reflexed over the sorus and in the young state more or less concealing it. Sporangia stalked, bursting transversely, girt by an incomplete vertical ring.

A genus of about 80 species, found in most tropical and temperate regions. It is only separated from *Nothochlaena* by the modified tooth or lobule of the frond reflexed over the sorus, a character which is sometimes so obscure that it is difficult to separate the two genera. The two New Zealand species are both widely distributed.

Fronds broad, deltoid .. .. 1. *C. tenuifolia.*
Fronds linear-oblong or linear .. .. 2. *C. Sieberi.*

1. **C. tenuifolia** *Swartz Syn. Fil.* (1806) 129, 332.—Rhizome very short, suberect, clothed with silky scales. Stipes 3–9 in. long, tufted, wiry, erect, dark red-brown, smooth and polished, glabrous or slightly scaly when young. Fronds 4–10 in. long, 2–4 in. broad, deltoid or ovate-deltoid, submembranous, yellowish-green, 3-pinnatifid; rhachis smooth, polished, glabrous or nearly so. Primary pinnae 6–12 on each side, opposite or nearly so, ascending or spreading; the lowest pair sometimes $2\frac{1}{2}$ in. long, deltoid; the upper smaller and narrower. Pinnules oblong or elliptic-oblong, deeply pinnatifid; ultimate segments entire or irregularly lobed or crenate; surfaces glabrous. Sori on the margins of the lobes, generally confluent and continuous all round the edge of the pinnules. Indusium narrow, elongated, usually crenate or denticulated, often transversely wrinkled.—*Hook. Sp. Fil.* ii (1858) 82, t. 87c; *Hook. and Bak. Syn. Fil.* (1873) 138; *Benth. Fl. Austral.* vii (1878) 726; *T. Kirk in Trans. N.Z. Inst.* (1874) 248; *Thoms. N.Z. Ferns* (1882) 57; *Field N.Z. Ferns* (1890) 86, t. 21, f. 2, 3; *Chesem. Man. N.Z. Fl.* (1906) 967. C. Kirkii *Armstr. in Trans. N.Z. Inst.* xiii (1881) 360 (*not of Hook.*). C. venosa *Col. in Trans. N.Z. Inst.* xxv (1893) 321. Pteris alpina *Field N.Z. Ferns* (1890) 97, t. 28, f. 2.

North Island: Auckland—Mount Maunganui, near Tauranga, *Mrs. Hetley!* Hawke's Bay—Mohaka, *E. Craig!* Petane, *A. Hamilton!* in various localities, *Colenso!* Wellington—Near Wanganui, *H. C. Field.* South Island: Canterbury—Banks Peninsula, *Lyall, Armstrong, T. Kirk!* Otago—Mountains near Lake Wakatipu, *Buchanan;* Lake Wanaka, *Mrs. Mason!* Sea-level to 2500 ft.

Extends northwards through Australia to the Malay Archipelago, India, and China. The typical state is easily distinguished from the following species by the broad deltoid frond, but intermediates are occasionally seen.

2. **C. Sieberi** *Kunze in Pl. Preiss.* ii (1847) 112.—Rhizome short, stout, creeping, clothed with chestnut-brown scales. Stipes 3–9 in. long, densely tufted, erect, wiry, dark chestnut-brown, polished, glabrous or with a few fibrillose scales. Fronds 3–9 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, linear-oblong or linear, erect, rigid, glabrous, 2–3-pinnatifid; rhachis smooth, glossy. Primary pinnae 3–15 opposite pairs, ascending, the lower rather remote, $\frac{1}{2}$–1 in. long, ovate-deltoid. Pinnules oblong, deeply pinnatifid; segments entire or cuneate, margins much recurved when dry. Sori roundish or oblong, distinct, or ultimately confluent and continuous round the margins of the pinnules. Indusium usually elongated, narrow; margins pale, entire or minutely denticulate.—*Hook. Sp. Fil.* ii (1858) 83, t. 97B; *Hook. and Bak. Syn. Fil.* (1873) 137; *Thoms. N.Z. Ferns* (1883) 58; *Field N.Z. Ferns* (1890) 87, t. 21, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 967. C. tenuifolia *A. Rich. Fl. Nouv. Zel.* (1832) 83; *A. Cunn. Precur.* (1836) n. 210; *Raoul Choix* (1846) 38; *Hook. f. Fl. Nov. Zel.* ii (1855) 23 (*for the greater part, but not of Swartz*). C. tenuifolia *var.* Sieberi *Hook. f. Handb. N.Z. Fl.* (1864) 362. C. erecta *Col. in Trans. N.Z. Inst.* xxviii (1896) 619.

North and South Islands: From the North Cape southwards, not uncommon in dry rocky places.

Abundant in Australia, and also found in New Caledonia and the Isle of Pines.

25. HYPOLEPIS Bernh.

Rhizome usually wide-creeping. Fronds large, 2–3-pinnate or decompound, often glandular or tomentose; texture membranous or herbaceous. Veins forked, free, never anastomosing. Sori small, globose, distinct, placed in the sinuses of the ultimate divisions of the frond. Indusium orbicular or reniform, membranous, composed of the modified margin of the frond, reflexed over the sorus and more or less covering it. Sporangia stalked, bursting transversely, with an incomplete vertical ring.

Species 24, confined to the tropics and the South Temperate Zone. Of the 3 species found in New Zealand, 2 are endemic, the remaining 1 extends to Australia, Polynesia, and the Malay Archipelago. The genus only differs from the *Phegopteris* section of *Dryopteris* by the sori being partly covered by an incurved lobule of the frond.

Fronds (with the stipes) 2–5 ft., deltoid, tomentose, 4-pinnate. Pinnules crenate-toothed .. .. 1. *H. tenuifolia.*

Fronds (with the stipes) 9–24 in., deltoid, almost glabrous, 3-pinnate, pale-green. Pinnules deeply and sharply toothed .. 2. *H. millefolium.*

Fronds (with the stipes) 6–20 in., lanceolate, almost glabrous, 2-pinnate, brownish-green. Pinnules deeply toothed .. .. 3. *H. distans.*

1. **H. tenuifolia** *Bernh. in Schrad. Neu Journ. Bot.* ii, 34.—Rhizome long, stout, creeping, densely clothed with red-brown linear scales. Stipes

1–2 ft. high or more, strong, erect, brown or yellow-brown, slightly rough with minute points, naked or pubescent, usually scaly towards the base. Fronds 1–3 ft. long, ½–2 ft. broad, ovate-oblong to broadly deltoid, pale-green, membranous or subcoriaceous, 4-pinnatifid; primary and secondary rhachises more or less tomentose with crisped hairs, rarely glabrous. Primary pinnae 8–20 in. long, 4–10 in. broad, ovate or ovate-lanceolate, acuminate; secondary and tertiary lanceolate or oblong-lanceolate. Ultimate divisions linear-oblong, obtuse or acute, crenate-toothed; costa and sometimes the under-surface more or less pubescent. Sori numerous, rounded, placed in the sinuses between the teeth or lobes. Indusium composed of the reflexed scale-like tip of a lobule of the frond, sometimes covering the sorus when young, often very inconspicuous when old.—*Hook. Sp. Fil.* ii (1858) 60, t. 89c and 90A; *Hook. f. Fl. Nov. Zel.* ii (1855) 22; *Handb. N.Z. Fl.* (1864) 361; *Hook. and Bak. Syn. Fil.* (1873) 129; *Benth. Fl. Austral.* vii (1878) 746; *Thoms. N.Z. Ferns* (1882) 56; *Field N.Z. Ferns* (1890) 84, t. 24, f. 3, *and* t. 27, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 965. H. dicksonioides *Hook. Sp. Fil.* ii (1858) 61. H. Petrieana *Carse in Trans. N.Z. Inst.* l (1918) 64. Cheilanthes ambigua *A. Rich. Fl. Nouv. Zel.* (1832) 84; *A. Cunn. Precur.* (1836) n. 211; *Raoul Choix* (1846) 38. C. arborescens *Swartz Syn. Fil.* (1806) 129, t. 336. C. pellucida *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 173. Lonchites tenuifolia *Forst. f. Prodr.* (1786) n. 424.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant throughout. Sea-level to 2000 ft.

Also in Norfolk Island, Australia, the Pacific islands, and Java. A most variable fern; in habit and general appearance often so close to *Phegopteris punctata* that the suspicion naturally arises that the two species may be forms of one plant, a view which is rendered more probable by the fact that the indusium is sometimes so feebly developed that the technical distinction separating *Hypolepis* and the *Phegopteris* section of *Dryopteris* is obliterated. Usually, however, *Polypodium punctatum* can be distinguished by

T.N.Z.I. Vol. 56, p. 82.

Hypolepis

"(1) H. tenuifolia Bernh.
(2) H. punctata (Thunb.) Mett. Syn. H. Petrieana Carse.
(3) H. rugosula (Labill.) J. Smith. Syn. Dryopteris punctata (see No.1 of this paper)."

North Island: Auckland—Mount Maunganui, near Tauranga, *Mrs. Hetley!* Hawke's Bay—Mohaka, *E. Craig!* Petane, *A. Hamilton!* in various localities, *Colenso!* Wellington—Near Wanganui, *H. C. Field.* South Island: Canterbury—Banks Peninsula, *Lyall, Armstrong, T. Kirk!* Otago—Mountains near Lake Wakatipu, *Buchanan;* Lake Wanaka, *Mrs. Mason!* Sea-level to 2500 ft.

Extends northwards through Australia to the Malay Archipelago, India, and China. The typical state is easily distinguished from the following species by the broad deltoid frond, but intermediates are occasionally seen.

2. **C. Sieberi** *Kunze in Pl. Preiss.* ii (1847) 112.—Rhizome short, stout, creeping, clothed with chestnut-brown scales. Stipes 3–9 in. long, densely tufted, erect, wiry, dark chestnut-brown, polished, glabrous or with a few fibrillose scales. Fronds 3–9 in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, linear-oblong or linear, erect, rigid, glabrous, 2–3-pinnatifid; rhachis smooth, glossy. Primary pinnae 3–15 opposite pairs, ascending, the lower rather remote, $\frac{1}{2}$–1 in. long, ovate-deltoid. Pinnules oblong, deeply pinnatifid; segments entire or cuneate, margins much recurved when dry. Sori roundish or oblong, distinct, or ultimately confluent and continuous round the margins of the pinnules. Indusium usually elongated, narrow; margins pale, entire or minutely denticulate.—*Hook. Sp. Fil.* ii (1858) 83, t. 97B; *Hook. and Bak. Syn. Fil.* (1873) 137; *Thoms. N.Z. Ferns* (1883) 58; *Field N.Z. Ferns* (1890) 87, t. 21, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 967. C. tenuifolia *A. Rich. Fl. Nouv. Zel.* (1832) 83; *A. Cunn. Precur.* (1836) n. 210; *Raoul Choix* (1846) 38; *Hook. f. Fl. Nov. Zel.* ii (1855) 23 (*for the greater part, but not of Swartz*). C. tenuifolia *var.* Sieberi *Hook. f. Handb. N.Z. Fl.* (1864) 362. C. erecta *Col. in Trans. N.Z. Inst.* xxviii (1896) 619.

North [illegible] Islands: From the North Cape southwards, not uncommon in dry [illegible], and also found in New Caledonia and the Isle of Pines.

rse.
s punctata

1–2 ft. high or more, strong, erect, brown or yellow-brown, slightly rough with minute points, naked or pubescent, usually scaly towards the base. Fronds 1–3 ft. long, ½–2 ft. broad, ovate-oblong to broadly deltoid, pale-green, membranous or subcoriaceous, 4-pinnatifid; primary and secondary rhachises more or less tomentose with crisped hairs, rarely glabrous. Primary pinnae 8–20 in. long, 4–10 in. broad, ovate or ovate-lanceolate, acuminate; secondary and tertiary lanceolate or oblong-lanceolate. Ultimate divisions linear-oblong, obtuse or acute, crenate-toothed; costa and sometimes the under-surface more or less pubescent. Sori numerous, rounded, placed in the sinuses between the teeth or lobes. Indusium composed of the reflexed scale-like tip of a lobule of the frond, sometimes covering the sorus when young, often very inconspicuous when old.—*Hook. Sp. Fil.* ii (1858) 60, t. 89c and 90a; *Hook. f. Fl. Nov. Zel.* ii (1855) 22; *Handb. N.Z. Fl.* (1864) 361; *Hook. and Bak. Syn. Fil.* (1873) 129; *Benth. Fl. Austral.* vii (1878) 746; *Thoms. N.Z. Ferns* (1882) 56; *Field N.Z. Ferns* (1890) 84, t. 24, f. 3, *and* t. 27, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 965. H. dicksonioides *Hook. Sp. Fil.* ii (1858) 61. H. Petrieana *Carse in Trans. N.Z. Inst.* l (1918) 64. Cheilanthes ambigua *A. Rich. Fl. Nouv. Zel.* (1832) 84; *A. Cunn. Precur.* (1836) n. 211; *Raoul Choix* (1846) 38. C. arborescens *Swartz Syn. Fil.* (1806) 129, t. 336. C. pellucida *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 173. Lonchites tenuifolia *Forst. f. Prodr.* (1786) n. 424.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant throughout. Sea-level to 2000 ft.

Also in Norfolk Island, Australia, the Pacific islands, and Java. A most variable fern; in habit and general appearance often so close to *Phegopteris punctata* that the suspicion naturally arises that the two species may be forms of one plant, a view which is rendered more probable by the fact that the indusium is sometimes so feebly developed that the technical distinction separating *Hypolepis* and the *Phegopteris* section of *Dryopteris* is obliterated. Usually, however, *Polypodium punctatum* can be distinguished by the sori being farther from the margin and by the glandular-viscid rhachis and costae. Mr. Colenso's *Cheilanthes pellucida*, which is kept as a distinct variety in the "Species Filicum" (t. 90a), looks different at first sight on account of its stouter habit, broader and more obtuse pinnules, and more copious crisped hairs, but is connected with the type by numerous intermediates. I am sorry that I cannot maintain Mr. Carse's *H. Petrieana*, which I take to be a state not uncommon in many parts of the North Island.

2. **H. millefolium** *Hook. Sp. Fil.* ii (1858) 68, t. 95b.—Rhizome long, slender, creeping, naked or nearly so. Stipes 3–9 in. long, rigid, erect, yellow-brown, glossy, smooth or slightly scabrous, glabrous or sparingly pilose with crisped hairs. Fronds 6–18 in. long, 3–9 in. broad, broadly ovate or deltoid to ovate-lanceolate, pale-green when fresh, firm or almost rigid, 4-pinnatifid; rhachis and costae more or less clothed with scattered crisped hairs. Primary and secondary pinnae ovate-lanceolate, ascending; tertiary ⅕–½ in. long, ovate or oblong, cut down almost to the rhachis into several entire or sharply-toothed lobes; under-surface glabrous or slightly hairy. Sori numerous, small, roundish, placed under a small lobule in the sinuses of the pinnules. Indusium composed of the reflexed and almost unaltered tip of the lobule.—*Hook. f. Fl. Nov. Zel.* ii (1855) 23; *Handb. N.Z. Fl.* (1864) 361; *Hook. and Bak. Syn. Fil.* (1873) 130; *Thoms. N.Z. Ferns* (1882) 56; *Field N.Z. Ferns* (1890) 85, t. 3, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 965.

North Island: East Cape district, *Bishop Williams;* base of Ruapehu, *H. C. Field! Cockayne;* Mount Egmont, *Buchanan, H. C. Field, T. F. C.;* Ruahine

Mountains, *Colenso! Field;* Manawatu Gorge, *A. Hamilton;* Tararua Mountains, *W. Townson, B. C. Aston!* SOUTH ISLAND: Not uncommon in mountain districts throughout. STEWART ISLAND: Base of Table Hill, *Cockayne.* CAMPBELL ISLAND, ANTIPODES ISLAND: *Kirk, Cockayne.* Usually from 1500 to 4000 ft., but descends almost to sea-level in the south of Otago.

Well distinguished from any of the forms of *H. tenuifolia* by the finely and deeply cut pinnules. It does not extend beyond New Zealand.

3. **H. distans** *Hook. Sp. Fil.* ii (1858) 70, t. 95c.—Rhizome long, rigid, branched, clothed with red-brown linear scales. Stipes 3–9 in. long, slender, flexuous, fragile, red-brown, glossy, naked, minutely muricate. Fronds 6–15 in. long, 3–6 in. broad, ovate-lanceolate, acuminate, rigid, brownish-green or reddish-brown, 2-pinnate; rhachis slender, red-brown, glabrous or nearly so, scabrous like the stipes. Primary pinnae 2–3 in. long, about $\frac{1}{2}$ in. broad, opposite or nearly so, distant, spreading at right angles, lanceolate; secondary (pinnules) $\frac{1}{4}$ in. long, sessile, lanceolate, rigid, deeply pinnatifid. Ultimate segments ovate, spreading, toothed or incised. Sori 2–8 to a pinnule, placed in the lower sinuses. Indusium composed of the inflexed tip of a lobule, small, membranous.—*Hook. f. Fl. Nov. Zel.* ii (1855) 23; *Handb. N.Z. Fl.* (1864) 362; *Hook. and Bak. Syn. Fil.* (1873) 129; *Thoms. N.Z. Ferns* (1882) 56; *Field N.Z. Ferns* (1890) 85, t. 28, f. 6; *Cheesem. Man. N.Z. Fl.* (1906) 966.

NORTH AND SOUTH ISLANDS, CHATHAM ISLANDS: In forest districts from the North Cape to the south of Otago, not common, usually at low elevations.

Small and slender forms of *Dryopteris punctata* are easily mistaken for this; but in its usual state it is a smaller and more slender plant, with more distant pinnae, and the frond is never densely hairy or viscid-pubescent. It is confined to New Zealand.

26. **ADIANTUM** Linn.

Rhizome creeping or tufted. Stipes usually long, often black and glossy. Fronds pinnate or 2–3-pinnate, never pinnatifid, rarely simple (in a few species not found in New Zealand). Pinnules more or less dimidiate or unilateral. Veins forked or repeatedly dichotomous, frequently radiating from the petiole to the margin. Sori marginal, varying in shape from reniform or globose to oblong or linear, usually numerous and distinct, sometimes confluent and continuous. Indusium the same shape as the sorus, composed of the altered margin of the frond, which is reflexed and bears the sporangia on its under-side, opening inwards. Sporangia stalked, bursting transversely; ring vertical, incomplete.

A well-marked genus of about 160 species, found in all tropical and subtropical countries, but most abundant in tropical South America, a few species found in the temperate zones of both hemispheres. All the New Zealand species extend to Australia, and the majority to the Pacific islands as well, while one has a very wide distribution in warm climates generally.

A. Pinnules flabellate-cuneate, attached by the middle of the base.

Fronds 2–3-pinnate, thin and membranous, glabrous. Pinnules small, orbicular with a cuneate base .. .. .. 1. *A. aethiopicum.*

B. Pinnules one-sided, obliquely oblong or rhomboid, attached by the lower corner of the pinnule.

* Sori in the deep notches between the teeth or lobules of the pinnules.

Fronds small, tender, simply pinnate or with 1–2 branches at the base. Pinnules sparsely setulose, rarely glabrous .. .. 2. *A. diaphanum.*

Fronds dichotomous, each division flabellately divided into 3–7 branches. Rhachis densely hispid .. .. .. 3. *A. hispidulum.*

** Sori in shallow excavations at the tips of the lobules of the pinnae, not in the notches between the lobules.

Fronds very large and compound, 3–5 ft. high with the stipes. Rhachis pubescent above. Pinnules small, ¼–½ in. Sori transversely oblong	4. *A. formosum.*
Fronds 1–2 ft. with the stipes. Rhachis smooth, polished. Pinnules ½–1 in., not falcate, glaucous beneath	5. *A. affine.*
Fronds 1–2 ft. with the stipes. Rhachis and costae clothed with fulvous hairs. Pinnules ½–¾ in., subfalcate, frequently setulose, not glaucous beneath	6. *A. fulvum.*

1. **A. aethiopicum** *Linn. Sp. Plant.* (1759) 1329.—Rhizome creeping, stoloniferous. Stipes 4–10 in. long, very slender, dark chestnut-brown, shining, quite glabrous. Fronds 6–12 in. long, rarely more, 3–6 in. broad, oblong to oblong-ovate or oblong-deltoid, erect or drooping, pale-green, very thin and membranous, flaccid, quite glabrous, 3–4-pinnate; rhachis very slender, almost capillary, flexuous, polished. Lower pinnae 2–4 in. long, ovate-deltoid. Pinnules on rather long and slender petioles, not dimidiate, ¼–⅓ in. long, often broader than long, variable in shape, usually suborbicular with a more or less cuneate base, upper margin broadly and shallowly lobed. Pinnules of barren fronds often larger, entire or obscurely lobed. Sori 2–6 to a pinnule, placed in the notches or sinuses between the lobes. Indusium rather large, reniform or transversely oblong, pale.—*Hook. Sp. Fil.* ii (1858) 37, t. 77A; *Hook. f. Fl. Nov. Zel.* ii (1855) 21; *Handb. N.Z. Fl.* (1864) 360; *Hook. and Bak. Syn. Fil.* (1873) 123; *Benth. Fl. Austral.* vii (1878) 724; *Thoms. N.Z. Ferns* (1882) 54; *Field N.Z. Ferns* (1890) 83, t. 17, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 960. A. assimile *Swartz Syn. Fil.* (1806) 125; *Raoul Choix* (1846) 38. A. trigonum *Labill. Pl. Nov. Holl.* ii (1806) 99, t. 248; *Raoul Choix* (1846) 38.

North Island: Plentiful in lowland districts from the North Cape to the Thames and Waikato Rivers, from thence rare and local to Hawke's Bay (*Colenso!*) and Taranaki (*H. C. Field!*). South Island: Has been reported from Nelson and Canterbury, but I have seen no specimens. Westland—Buller River, near Westport, *Townson!*

An abundant fern in most tropical and subtropical countries.

2. **A. diaphanum** *Blume Enum.* (1828) 215.—Rhizome very short, tufted; rootlets long, fibrous, densely tomentose, bearing numerous small oblong tubers. Stipes 2–6 in. long, very slender, almost capillary, wiry, glabrous or slightly scaly towards the base, dark purplish-brown or almost black. Fronds 3–6 in. long, rarely more, simply pinnate, or with 1–2 branches at the base which are sometimes almost as long as the central portion but usually much shorter, thin and membranous, flaccid, dark-green; branches ½–1 in. diam. Pinnules numerous, shortly petiolate, ⅓–½ in. long, about ¼ in. deep, dimidiate-oblong; lower margin straight or more or less decurved, entire; upper margin about parallel, and together with the rounded apex deeply crenate-toothed; surfaces sparingly setulose with minute stiff black hairs. Sori 4–8 to a pinnule, rarely more, placed in the notches of the upper and outer margins. Indusium reniform, pale, minutely setulose.—*Hook. Sp. Fil.* ii (1858) 10, t. 80c; *Hook. and Bak. Syn. Fil.* (1873) 117; *Thoms. N.Z. Ferns* (1882) 53; *Field N.Z. Ferns* (1890) 80, t. 13, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 961. A. affine *Hook.*

Sp. Fil. ii (1858) 32; *Hook. f. Fl. Nov. Zel.* ii (1855) 20; *Handb. N.Z. Fl.* (1864) 360 (*not of Willd.*). A. setulosum *J. Smith in Comp. Bot. Mag.* (1846) 22.

Var. **polymorphum** *Cheesem.*—Fronds smaller, pale-greem, usually simply pinnate, rarely branched at the base. Surfaces of the pinnae and indusia quite glabrous.—A. polymorphum *Col. in Trans. N.Z. Inst.* xx (1888) 215. A. tuberosum *Col. l.c.* 217.

Kermadec Islands, North Island: Not uncommon in woods at low elevations, usually in rich alluvial soils. South Island: Apparently rare and local. Nelson—Bateman's Gully, *D. Grant;* Collingwood, *H. H. Travers;* Lake Tennyson, *Laing.* Canterbury—Gorge of the Rakaia, *Potts.* Otago—Various localities, *Buchanan, T. Kirk.* Sea-level to 1000 ft.

Also in Norfolk Island, east Australia, Fiji, New Caledonia, New Hebrides, Java, and southern China.

3. **A. hispidulum** *Swartz Syn. Fil.* (1806) 124.—Rhizome short, stout, creeping. Stipes 6–15 in. long, stout, erect, scabrous, dark-brown or almost black, more or less clothed with short greyish-white pubescence when young, becoming almost glabrous when old. Fronds broad, 6–12 in. or more across, dichotomously forked at the base, both forks irregularly flabellately divided into 3–7 linear secondary divisions 3–8 in. long by ½–¾ in. broad, colour olive-green, often red or reddish-brown when young, rhachises densely hispid-pubescent. Pinnules numerous, closely placed, petiolate, ⅓–⅔ in. long, about ¼ in. deep, dimidiate, rhomboidal, rigid, prominently nerved, more or less hispid, especially on the under-surface, upper margin and the obtuse tip finely toothed, lower margin entire. Sori numerous on each pinnule, contiguous, placed in the notches of the upper and outer margins. Indusium orbicular-reniform, minutely hispid.—*A. Rich. Fl. Nouv. Zel.* (1832) 88; *A. Cunn. Precur.* (1836) n. 209; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* ii (1858) 31; *Hook. f. Fl. Nov. Zel.* ii (1855) 22; *Handb. N.Z. Fl.* (1864) 360; *Hook. and Bak. Syn. Fil.* (1873) 126; *Benth. Fl. Austral.* vii (1878) 725; *Thoms. N.Z. Ferns* (1882) 55; *Field N.Z. Ferns* (1890) 82, t. 13, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 962. A. pubescens *Schkuhr Fil.* (1809) 108, t. 115; *A. Rich. Fl. Nouv. Zel.* (1832) 89. A. pedatum *Forst. f. Prodr.* (1786) n. 468 (*not of Linn.*).

Kermadec Islands, North Island: Abundant as far south as the East Cape and Raglan, from thence somewhat rare and local to Cook Strait. South Island: Nelson—Bishopdale, *D. Grant.*

The rather harsh hispid-pubescent fronds distinguish this from all the other New Zealand species. Outside New Zealand, it extends through the Pacific islands and Australia to tropical Asia and Africa.

4. **A. formosum** *R. Br. Prodr.* (1810) 155.—Rhizome long, stout, creeping, scaly. Stipes 1–3 ft. high, dark purplish-black or quite black, shining, sometimes hairy towards the base, scabrous throughout. Fronds 1½–3 ft. long, 12–20 in. broad, broadly deltoid, dark-green, copiously 3–4-pinnate; main rhachis flexuous, black, glossy, glabrous or pubescent; secondary rhachises usually pubescent. Lower pinnae large and broad, often 12–15 in. long, ascending, very compound; secondary pinnae usually again divided. Pinnules very numerous; fertile small, ¼–½ in. long, ⅕–¼ in. deep, petiolate, dimidiate, broadly obliquely-oblong or rhomboid; lower margin straight or slightly hollowed, entire, upper and the rounded outer margin deeply toothed or incised; texture firm; under-surface glabrous or pubescent with

scattered white hairs. Pinnules of the barren frond larger, often $\frac{3}{4}$ in. long or more, more membranous, upper and outer margins deeply lobulate, the lobules incised. Sori numerous, placed in shallow depressions at the top of the teeth or lobules, broader than long, transversely oblong or oblong-reniform.—*Hook. Sp. Fil.* ii (1858) 51, t. 86B; *Hook. f. Fl. Nov. Zel.* ii (1855) 21; *Handb. N.Z. Fl.* (1864) 360; *Hook. and Bak. Syn. Fil.* (1873) 119; *Benth. Fl. Austral.* vii (1878) 724; *Thoms. N.Z. Ferns* (1882) 54; *Field N.Z. Ferns* (1890) 81, t. 6; *Cheesem. Man. N.Z. Fl.* (1906) 962.

North Island: Auckland—Alluvial banks of the Northern Wairoa River, from Tangiteroria to a few miles above Dargaville, *T. F. C.* Wellington—Manawatu River and its tributaries, from Woodville to below Palmerston North, *Colenso! Enys! Field! Hamilton!* &c.

Also a native of eastern Australia. Easily recognized by its large size, decompound fronds, and numerous small somewhat rigid pinnules.

A. cunninghamii Hook. --- C. Chr. Index Filicum 1906:25

5. **A. affine** *Willd. Sp. Plant.* v (1810) 448.—Rhizome long, creeping, stout, clothed with glossy dark chestnut-brown scales. Stipes 4–12 in. long or more, stout, erect, shining-black, rough and scaly at the very base, smooth and polished above. Fronds 6–15 in. long, 3–9 in. broad, ovate-deltoid in outline, bipinnate or tripinnate at the base, pale-green above, usually glaucous beneath, quite glabrous or the secondary rhachises pubescent above. Pinnae 2–3 pairs with a long terminal one sometimes 6–9 in. long, in large specimens the lowest pair again branched. Pinnules $\frac{1}{2}$–1 in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. deep, petiolate, dimidiate, broadly obliquely-oblong or rhomboidal; lower margin straight, entire, base truncate; upper margin and the obtusely rounded apex deeply crenate-toothed; texture firm, subcoriaceous. Sori numerous, rather large, 6–14 to a pinnule, placed in small notches at the tips of the lobes of the upper and outer margins, not in the sinuses between the lobes. Indusium orbicular-cordate or reniform.—*Hook. and Bak. Syn. Fil.* (1873) 117; *Benth. Fl. Austral.* vii (1878) 724; *Thoms. N.Z. Ferns* (1882) 53; *Field N.Z. Ferns* (1890) 80, t. 6, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 963. A. Cunninghamii *Hook. Sp. Fil.* ii (1858) 52, t. 86A; *Hook. f. Fl. Nov. Zel.* ii (1855) 21; *Handb. N.Z. Fl.* (1864) 360. A. formosum *A. Rich. Fl. Nouv. Zel.* (1832) 88; *A. Cunn. Precur.* (1836) n. 208; *Raoul Choix* (1846) 38 (*not of R. Br.*). A. pullum *Col. in Trans. N.Z. Inst.* (1873) 319.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant in lowland districts throughout.

Also in Australia, according to Bentham (Fl. Austral. vii (1878) 724). Very variable in size, the amount of branching of the frond, and in the size and shape of the pinnules. When growing on exposed rock-faces it is often dwarfed to an inch or two. Most of the Chatham Islands specimens that I have seen are less compound, with larger and coarser narrower pinnules, corresponding, I presume, with the variety *Chathamicum* of Mr. Field (N.Z. Ferns, 81). A curious form gathered by Mr. Hamilton on limestone crags at Moteo, near Puketapu, Hawke's Bay, has the tips of the pinnae largely cristate, and the pinnules very irregular in shape. It is the *A. Cunninghamii* var. *heterophyllum* of Colenso (Trans. N.Z. Inst. xx (1888) 218). States with the secondary rhachises somewhat pubescent above, and with rather narrower and more acute pinnules, seem to show a marked approach to *A. fulvum*.

6. **A. fulvum** *Raoul Choix* (1846) 9.—Rhizome long, creeping, clothed with brownish subulate scales. Stipes 4–12 in. long, erect, dark reddish-brown or almost black, rough with minute projections throughout, more or less scaly towards the base. Fronds 6–15 in. long, 3–9 in. broad, ovate-deltoid in outline, 2–3-pinnate or rarely in large specimens 4-pinnate

at the base, olive-green or pale-green, not glaucous beneath; rhachis and costae more or less densely clothed above with strigose fulvous hairs. Pinnae 2–4 pairs with a long terminal one, in small specimens not branched, in larger ones the lowest pair and sometimes all again divided, or rarely the lowest pair twice branched. Pinnules $\frac{1}{2}$–$\frac{3}{4}$ in. long, about $\frac{1}{4}$ in. deep, petiolate, dimidiate, obliquely oblong, often slightly falcate; lower margin curved or nearly straight, entire; upper margin almost parallel, deeply crenate; lower surface often minutely setulose with stiff fulvous hairs; texture firm but not coriaceous. Sori usually numerous in shallow notches at the tips of the lobes of the upper and outer margins, not in the sinuses between the lobes. Indusium orbicular-cordate, often pale when young.—*Hook. Sp. Fil.* ii (1858) 52, t. 85A; *Hook. f. Fl. Nov. Zel.* ii (1855) 22; *Handb. N.Z. Fl.* (1864) 361; *Hook. and Bak. Syn. Fil.* (1873) 120; *Thoms. N.Z. Ferns* (1882) 54; *Field N.Z. Ferns* (1890) 81, t. 6, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 964. A. viridescens *Col. in Trans. N.Z. Inst.* xxvii (1895) 400.

North and South Islands: Lowland districts as far south as Banks Peninsula, not uncommon.

Very close indeed to *A. affine*, with which it certainly seems to me to be connected by intermediate forms. It is more copiously branched, the rhachis and costae are clothed with strigose fulvous hairs, the stipes is minutely muricate, and the pinnules are narrower and subfalcate, and often setulose beneath. It is also found in Norfolk Island, New South Wales, and Fiji.

27. **PTERIS** Linn.

Rhizome usually creeping. Fronds of very various habit, generally much divided, often of large size. Veins free or more or less copiously anastomosing. Sori marginal, linear, continuous, placed on a slender receptacle running along the edge of the frond, and joining the tips of the transverse veinlets. Indusium long, narrow, continuous, always single, composed of the more or less modified and membranous reflexed margin of the frond. Sporangia stalked, bursting transversely, girt by an incomplete vertical ring. Spores tetrahedral.

Although this genus has been reduced in size by the separation of a number of small groups formerly included in it, it still contains at least 125 species. These are widely spread in the tropics of both hemispheres, but few extending into the Temperate Zones. Of the 3 New Zealand species, 1 is endemic; the remaining 2 are found in Australia, Tasmania, and Norfolk Island.

Veins free. Fronds 1–3 ft., membranous, glabrous. Segments $\frac{1}{2}$–$1\frac{1}{2}$ in. long, obtuse .. .. 1. *P. tremula.*

Veins anastomosing. Fronds 2–4 ft., dark-green, 2-pinnate or rarely 3-pinnate. Segments of the pinnules lanceolate or linear-lanceolate, 1–3 in. long, entire or toothed at the tip .. .. .. 2. *P. comans.*

Veins anastomosing. Fronds 1–3 ft., pale-green, 2–4-pinnate. Pinnules remote, stalked, ovate or deltoid, deeply lobed.. .. 3. *P. macilenta.*

[*P. lomarioides* Col. in Trans. N.Z. Inst. xiii (1880) 380, said to have been collected near Tapuaeharuru, Taupo, is proved by the type specimen in Mr. Colenso's herbarium to be the widely distributed *P. cretica* Linn. Although it is just possible that the species may exist near some of the hot springs at Taupo, where other tropical ferns, such as *Gleichenia dichotoma, Nephrodium unitum* and *N. molle* are known to grow, still, as the locality has been repeatedly searched without success, the most prudent course is to wait for further evidence before introducing the species into the Flora. The same course must be followed with respect to *P. longifolia* Linn., an equally widely spread

plant, stated by Mr. Buchanan (Trans. N.Z. Inst. xiv (1882) 356) to have been gathered at Tarawera, between Napier and Taupo, but of which there are no indigenous specimens in any New Zealand herbarium.]

1. **P. tremula** *R. Br. Prodr.* (1810) 154.—Rhizome short, stout, suberect, putting up numerous tufted erect fronds. Stipes 1–2 ft. long, stout, erect, quite glabrous, smooth and polished, bright chestnut-brown, darker at the base. Fronds 1–3 ft. long or more, 6–24 in. broad, ovate or ovate-deltoid, acuminate, bright-green, herbaceous, quite glabrous, 2–4-pinnate; rhachis smooth, naked. Primary pinnae 6–12 pairs, subopposite; the lowest 6–15 in. long, ovate-lanceolate or ovate-deltoid, usually bipinnate, sometimes tripinnate; upper gradually becoming shorter and narrower and less compound; the uppermost linear, pinnate or pinnatifid. Ultimate segments ½–1½ in. long, $\frac{1}{10}$–$\frac{1}{6}$ in. broad, linear or linear-oblong, obtuse, sessile and decurrent at the base; fertile usually entire or slightly crenate at the tips; barren generally broader and with the margins crenate throughout; veins free, forked. Sori copious, usually continuous on both the upper and lower edges of the segments, rarely interrupted.—*Hook Sp. Fil.* ii (1858) 174, t. 120B; *Hook. f. Fl. Nov. Zel.* ii (1855) 25; *Handb. N.Z. Fl.* (1864) 364; *Hook. and Bak. Syn. Fil.* (1873) 161; *Benth. Fl. Austral.* vii (1878) 731; *Thoms. N.Z. Ferns* (1882) 60; *Field N.Z. Ferns* (1890) 90, t. 23, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 971. P. affinis *A. Rich. Fl. Nouv. Zel.* (1832) 81; *A. Cunn. Precur.* (1836) n. 201; *Raoul Choix* (1846) 38. P. tenuis *A. Cunn. Precur.* (1836) n. 205. P. Kingiana *Endl. Prodr. Fl. Insl. Norfolk* (1833) 13.

Kermadec Islands, North Island: Abundant, ascending to 2500 ft. South Island: In various localities in Nelson and Marlborough, but not common; recorded from Banks Peninsula by Armstrong and Potts.

Also in Australia and Tasmania, Norfolk Island, Lord Howe Island, and Fiji Very variable in the size and shape of the ultimate segments. *P. Kingiana* (var. *Kingiana* Hook. and Bak. Syn. Fil. (1873) 161) sometimes has them over 1½ in. long and more than ¼ in. broad; while in *P. tenuis* A. Cunn. they are very narrow, the sori occupying the whole under-surface except the costa.

2. **P. comans** *Forst. f. Prodr.* (1786) n. 419.—Rhizome short, stout, suberect. Stipes 1–2 ft. long or more, erect, yellow-brown, polished, naked or clothed at the base with dark-brown scales. Fronds 1–4 ft. long, ½–3 ft. broad, broadly deltoid, acuminate, membranous, dark-green, quite glabrous, 2-pinnate or rarely 3-pinnate at the base; rhachis smooth, polished. Lower pinnae in large specimens nearly 2 ft. long by 1 ft. broad and bipinnate, but usually from 9–18 in. and pinnate, shortly stalked; upper pinnae gradually becoming shorter and narrower, oblong-lanceolate or lanceolate, regularly pinnatifid; terminal pinna 6–9 in. long, cut down almost to the rhachis. Ultimate segments variable in size and shape, 1–3 in. long, ¼–½ in. broad, lanceolate or linear-lanceolate to linear-oblong, acute or obtuse, straight or falcate, the fertile ones serrate at the tips or sinuate-serrate or sinuate-lobed, sinus between the segments acute. Veins anastomosing copiously. Sori continuous, but not reaching the apex of the segments.—*A. Rich. Fl. Nouv. Zel.* (1832) 79; *A. Cunn. Precur.* (1836) n. 199; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* ii (1858) 219; *Hook. f. Fl. Nov. Zel.* ii (1855) 26; *Hook. and Bak. Syn. Fil.* (1873) 171; *Benth. Fl. Austral.* vii (1878) 733; *Thoms. N.Z. Ferns* (1882) 62; *Field N.Z. Ferns* (1890) 95, t. 24, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 972. P. Endlicheriana *Aghard*

Sp. Pterid. (1839) 66 ; *Hook. Ic. Plant.* (1854) t. 973 ; *Sp. Fil.* ii (1858) 218 ; *Hook. f. Handb. N.Z. Fl.* (1864) 364. Litobrochia comans *Presl Tent. Pteridogr.* (1836) 66.

Kermadec Islands : Most abundant, *McGillivray, T. F. C., Oliver.* North Island : From the Three Kings Islands and the North Cape southwards to the Bay of Plenty, usually in shaded places near the sea, plentiful on the outlying islands, rare and local on the mainland.

This is often confounded by fern-collectors with large states of *P. macilenta* var. *pendula*, but is an altogether different plant, with a coarser and stouter habit of growth, much-broader less-divided fronds, and usually long and narrow segments, with the venation more copiously anastomosing. It is also found in Australia, Tasmania, and the Pacific islands.

3. **P. macilenta** *A. Rich. Fl. Nouv. Zel.* (1832) 82, t. 11.—Rhizome very short, suberect, clothed with the bases of the old stipites. Stipes 6–12 in. long, pale yellow-brown, becoming darker towards the base, smooth or slightly scaly below. Fronds 1–3 ft. long, 9–18 in. broad, broadly ovate or deltoid, membranous, flaccid, pale-green and glistening, quite glabrous, 2–3-pinnate ; rhachis smooth, stramineous. Primary pinnae numerous, distant, the lower ones 6–12 in. long, the upper gradually shorter ; terminal pinna 1–3 in. long, acuminate, deeply pinnatifid. Secondary pinnae stalked, those on the lower branches again pinnate, on the upper pinnatifid. Pinnules 1–2 in. long, scattered, often remote, stalked, ovate or deltoid, cuneate at the base, pinnatifid, the terminal ones adnate and decurrent. Ultimate segments oblong or ovate, deeply and coarsely toothed or incised at the apex. Veins anastomosing along the costa, free elsewhere. Sori in the notches between the segments, short, not nearly reaching the tips of the segments.—*A. Cunn. Precur.* (1836) n. 202 ; *Raoul Choix* (1846) 38 ; *Hook. Sp. Fil.* ii (1858) 219 ; *Hook. f. Fl. Nov. Zel.* ii (1855) 26 ; *Handb. N.Z. Fl.* (1864) 364 ; *Hook. and Bak. Syn. Fil.* (1873) 171 ; *Thoms. N.Z. Ferns* (1882) 61 ; *Field N.Z. Ferns* (1890) 94, t. 7, f. 1 ; *Cheesem. Man. N.Z. Fl.* (1906) 973. Litobrochia macilenta *Brack. in U.S. Expl. Exped.* (1854) 106.

Var. **saxatilis.**—*Carse in Trans. N.Z. Inst.* li (1919) 95.—Smaller and thinner than the type, decumbent or suberect. Pinnules much smaller, more deeply toothed, the tips of the segments often laciniate.

Var. **pendula.**—Not so finely divided. Terminal pinna larger, 3–5 in. long, often caudate. Pinnules larger, 2–2½ in. long, ovate, acuminate ; segments longer and narrower.—P. pendula *Col. in Trans. N.Z. Inst.* xx (1888) 218.

North Island : The type and varieties not uncommon throughout in dry woods. South Island : Nelson—Near Nelson, *T. F. C. ;* Takaka, *Kingsley.* Marlborough—*Buchanan.* Also said to occur on Banks Peninsula and near Greymouth, but I have seen no specimens.

28. **HISTIOPTERIS** Aghard.

Rhizome long, stout, creeping. Fronds tall, 1–8 ft. high, erect, sometimes almost subscandent, smooth and glaucous beneath, 2–3-pinnate. Primary pinnae horizontally spreading, opposite and sessile ; ultimate divisions entire or sinuate or pinnatifid. Venation very variable, sometimes wholly free or partly united, at others altogether anastomosing. Sori marginal, linear, placed on a slender receptacle connecting the tips of the veins or their anastomoses. Indusium single, formed of the reflexed margin of the frond, membranous. Sporangia stalked, bursting transversely. Spores bilateral.

A small genus of one or two species, widely distributed through the tropics and the South Temperate Zone, extending southwards to the Subantarctic islands. It is very closely allied to *Pteridium*, from which it chiefly differs in the venation, and in the absence of the inner indusium.

1. **H. incisa** *J. Smith Hist. Fil.* (1875) 352.—Rhizome long, creeping, rather slender, smooth, producing numerous scattered fronds. Stipes 1–3 ft. high or more, stout, erect, smooth and glossy, yellow-brown or red-brown when mature, often glaucous when young, naked or slightly scabrous at the base. Fronds variable in size, 2–4 ft. long, broadly deltoid or ovate-deltoid to ovate-lanceolate, membranous when young, firm in age, quite smooth and glabrous, glaucous-green, 2–3-pinnate ; rhachis pale chestnut-brown, smooth and polished. Primary pinnae large, 6–12 in. long or more, ovate-lanceolate, opposite or nearly so, rather distant, sessile, the opposite pairs often almost connate at the base, 2-pinnatifid or the uppermost simply pinnate. Secondary pinnae lanceolate, deeply pinnatifid, sometimes pinnate at the base. Ultimate segments oblong or oblong-deltoid, obtuse, those of the barren fronds often sinuate-dentate or lobed. Veins sometimes all free, but usually more or less anastomosing near the costa of the pinnules. Sori continuous or interrupted, seldom reaching either the base or apex of the segment.—Pteris incisa *Thunb. Fl. Cap.* (1800) 171 ; *Hook. Sp. Fil.* ii (1858) 230 ; *Hook. f. Handb. N.Z. Fl.* (1864) 364 ; *Hook. and Bak. Syn. Fil.* (1873) 172 ; *Benth. Fl. Austral.* vii (1878) 732 ; *Thoms. N.Z. Ferns* (1882) 62 ; *Field N.Z. Ferns* (1890) 96, t. 8, f. 4 ; *Cheesem. Man. N.Z. Fl.* (1906) 973. P. vespertilionis *Labill. Pl. Nov. Holl.* ii (1806) 96, t. 245 ; *Hook. f. Fl. Antarct.* i (1844) 110 ; *Fl. Nov. Zel.* ii (1855) 26. P. Brunoniana *Endl. Prodr. Insl. Norfolk* (1833) 12 ; *A. Cunn. Precur.* (1836) n. 202 ; *Raoul Choix* (1846) 38. P. montana *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 172. Litobrochia incisa and L. vespertilionis *Presl Tent. Pterid.* (1836) 149.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands, Antipodes Island : Abundant throughout, often forming thickets on the skirts of woods, &c. Sea-level to 3000 ft.

Universally spread through the tropics and the South Temperate Zone. In New Zealand it attains exceptional luxuriance by the margins of hot springs in the Rotorua and Taupo districts, in some localities reaching a height of 12 ft.

29. **PTERIDIUM** Gled.

Rhizome stout, creeping, subterranean. Stipites strong, stout, erect and rigid, often remote from one another. Fronds large, broad, deltoid, much divided, 3–4-pinnate. Veins simple or forked, never anastomosing. Sori marginal, linear, continuous, placed on a slender receptacle connecting the tips of the veins. Indusium double ; the outer one formed of the reflexed margin of the frond, membranous, usually villous or ciliated ; the inner less evident, arising from the inner side of the receptacle, sometimes obsolete. Sporangia stalked, bursting transversely, girt by an incomplete vertical ring.

Treated in the sense of the " Pflanzenfamilien " and Christensen's " Index Filicum," this is a genus composed of a single highly variable and widely spread species ; but some authors split it into four or five closely related forms. It is mainly distinguished from *Pteris* proper by the distinctly double indusium.

1. **P. aquilinum** *Kuhn in Deck. Reis. Bot.* iii (1879) 11 ; *var.* **esculenta** *Hook f. Fl. Nov. Zel.* ii (1855) 25.—Rhizome stout, as thick as the finger, creeping, much branched, often matted, subterranean, producing numerous scattered fronds. Stipes variable in length, stout, rigid, erect, brown, smooth and shining. Fronds usually from 2–6 ft. long including the stipes, but often taller and sometimes 10–12 ft., broadly deltoid in outline, coriaceous, glabrous or nearly so when mature, usually more or less rusty-pubescent when young, especially on the under-surface, 3–4-pinnate ; rhachises grooved above, usually pubescent. Primary pinnae broad, distant, spreading, the lowest pair the largest and most compound, the upper ones gradually decreasing in size ; secondary and tertiary lanceolate, always terminating in a linear obtuse undivided segment. Ultimate segments linear or linear-oblong, decurrent at the base. Veins free, once or twice forked. Sori usually continuous all round the segment, and often extending to the decurrent base. Indusium double, but the inner one often very inconspicuous.—*Hook. Sp. Fil.* ii (1858) 197, t. 141B ; *Hook. f. Handb. N.Z. Fl.* (1864) 353 ; *Hook. and Bak. Syn. Fil.* (1873) 163 ; *Benth. Fl. Austral.* vii (1878) 731 ; *Thoms. N.Z. Ferns* (1882) 60 ; *Field N.Z. Ferns* (1890) 92, t. 14, f. 1, 1A ; *Cheesem. Man. N.Z. Fl.* (1906) 970. P. esculenta *Forst. f. Prodr.* (1786) n. 488 ; *Pl. Escul.* (1786) 74 ; *A. Rich. Fl. Nouv. Zel.* (1832) 79 ; *A. Cunn. Precur.* (1836) n. 200 ; *Raoul Choix* (1846) 38.

KERMADEC ISLANDS, NORTH AND SOUTH ISLANDS, CHATHAM ISLANDS, STEWART ISLAND, AUCKLAND AND CAMPBELL ISLANDS : Abundant throughout, except in dense forest, often covering extensive areas, especially in the North Island. *Common fern ; Bracken ; Rau-aruhe ; Rahurahu ;* of the root *Aruhe, Roi.* Sea-level to 4000 ft.

P. aquilina, in some of its forms, is almost cosmopolitan ; the variety *esculenta,* which chiefly differs in the decurrent bases of the pinnules, is confined to the Southern Hemisphere. The starchy rhizome formerly constituted one of the chief vegetable foods of the Maoris. For an account of the mode of its preparation, and many interesting particulars concerning its use, reference should be made to Mr. Colenso's paper " On the Vegetable Food of the Ancient New-Zealanders " (Trans. N.Z. Inst. xiii, pp. 1–38).

30. **PAESIA** St. Hil.

Rhizome long, creeping, scaly. Stipes stiff, erect ; rhachis often more or less flexuose. Frond finely divided, 3–4-pinnate, usually glandular-scabrous or -villous ; ultimate segments deeply lobed or toothed. Veins free. Sori marginal, linear, placed on a slender receptacle connecting the tips of the veins. Indusium usually double ; the outer one formed of the reflexed margin of the frond ; the inner, when present, arising from the inner side of the receptacle. Sporangia stalked, bursting transversely ; girt by an incomplete vertical ring. Spores bilateral.

A small genus of six or seven species distributed through the southern tropics. It is very closely allied to *Pteridium,* and might well be incorporated with it, as in fact was done in the " Synopsis Filicum." The single New Zealand species is endemic.

1. **P. scaberula** *Kuhn Chaetopt.* (1882) 347.—Rhizome wide-creeping, rigid, wiry, clothed with chestnut-brown scales. Stipes 4–12 in. long, rigid, erect, yellow-brown or chestnut-brown, scabrous, glandular-pubescent and usually more or less bristly. Fronds 9–18 in. high, rarely more, 4–9 in. broad, ovate or ovate-lanceolate, acuminate, rigid, coriaceous, pale yellow-green, usually copiously glandular-pubescent on both surfaces, rarely almost

glabrate; rhachis scabrous, flexuous. Primary pinnae numerous, the lowest pair often distant, lanceolate or ovate-lanceolate, 3–9 in. long; secondary lanceolate. Ultimate divisions small, $\frac{1}{10}$–$\frac{1}{4}$ in. long, stipitate, acute, entire or the barren ones toothed or incised, often lobed or pinnatifid at the base; veins obscure. Sori copious, when mature usually covering the whole segment except the costa and the extreme tip and base.—Pteris scaberula *A. Rich Fl. Nouv. Zel.* (1832) 82, t. 11; *A. Cunn. Precur.* (1836) n. 204; *Raoul Choix* (1846) 38; *Hook. Sp. Fil.* ii (1858) 174, t. 93A; *Hook. f. Fl. Nov. Zel.* ii (1855) 25; *Handb. N.Z. Fl.* (1864) 364; *Hook and Bak. Syn. Fil.* (1873) 163; *Thoms. N.Z. Ferns* (1882) 61; *Field N.Z. Ferns* (1890) 94, t. 19, f. 5; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 239. P. microphylla *A. Cunn. Precur.* (1836) n. 206; *Raoul Choix* (1846) 48. Allosurus scaberulus *Presl Tent. Pterid.* (1836) 154.

North and South Islands, Stewart Island, Chatham Islands: Abundant throughout, usually on bank-sides, or in dry open places in woods. Sea-level to 2500 ft.

Easily distinguished from its allies in New Zealand by the finely divided frond and minute coriaceous pinnules. In the North Island it quickly takes possession of the sides of road-cuttings in forest districts, often to the exclusion of other vegetation.

31. **POLYPODIUM** Linn.

Rhizome short and tufted, or long and creeping. Stipes jointed on to the rhizome, not continuous with it. Fronds very variable in size, shape, and cutting, simple or pinnatifid or pinnate in the New Zealand species. Veins free or copiously anastomosing. Sori globose or oblong, placed on the back of the frond, either at the tip of a vein or on the back of one. Indusium wanting. Sporangia stalked, surrounded by an incomplete vertical ring, bursting transversely.

In this work I have followed the circumscription of *Polypodium* adopted by Diels in the "Pflanzenfamilien," and by Christensen in the "Index Filicum." This differs from the *Polypodium* of Hooker and Baker in the excision of all those species that have the stipes continuous with the rhizome, or, in other words, belong to the Desmobryoid series of ferns. All these are now placed with their nearest allies in the genus *Dryopteris*, a name which, under the law of priority, takes the place of the better known *Nephrodium*. Some smaller groups of species have also been removed from the genus for reasons that need not be particularized here. Notwithstanding these losses, the genus *Polypodium* still remains the largest among ferns, numbering over seven hundred species. Of the six species found in New Zealand, one (*P. novae-zealandiae*) is endemic; another (*P. dictyopteris*) is also found in the New Hebrides; a third species (*P. Billardieri*) has a wide distribution in the South Temperate Zone; while the remaining three occur in Australia, Tasmania, and Norfolk Island.

* *Veins all free.*

Rhizome short. Fronds small, 1–6 in., quite entire. Sori oblong or linear-oblong, oblique to the midrib .. .. 1. *P. Billardieri.*

Rhizome short. Fronds 3–9 in., irregularly pinnatifid or 2-pinnatifid; pinnae linear. Sori oblong or rounded .. 2. *P. grammitidis.*

** *Veins copiously anastomosing.*

Rhizome short. Fronds 4–12 in., tufted, lanceolate, simple and entire .. .. 3. *P. dictyopteris.*

Rhizome long, slender, clothed with squarrose scales. Fronds 6–18 in., simple or pinnatifid, membranous; segments narrow .. .. 4. *P. pustulatum.*

Rhizome long, stout, clothed with appressed scales. Fronds 6–18 in., simple or pinnatifid, coriaceous; segments broad .. .. 5. *P. diversifolium.*

Rhizome long, stout, clothed with spreading scales. Fronds 1–4 ft., pinnatifid or pinnate, thinly coriaceous; segments usually narrow .. .. 6. *P. novae-zealandiae.*

1. **P. Billardieri** *C. Christen. Ind. Fil.* (1906) 513.—Rhizome very short, or erect or oblique and lengthened to ½–1½ in. long, crowned with copious pale chestnut-brown scales; rootlets long, wiry, densely hairy; often several rhizomes and their rootlets are matted together in the same tuft. Fronds numerous, crowded towards the end of the rhizome, erect, 1–6 in. long, ⅙–⅓ in. broad, linear-lanceolate or narrow-oblanceolate or linear-spathulate, quite entire, obtuse at the tip, very gradually narrowed into a short winged stipes, dark-green, coriaceous, glabrous or sparingly ciliate with short whitish hairs towards the base. Veins obscure, hidden in the substance of the frond. Sori in a single row on each side of the midrib and nearer to it than to the margin, oblique to the midrib, usually numerous, rather large, oblong or linear-oblong, often confluent when old.—P. australe *Mett. Polyp.* 36; *Hook. Sp. Fil.* iv (1862) 167; *Hook. f. Handb. N.Z. Fl.* (1864) 380; *Hook. and Bak. Syn. Fil.* (1873) 322; *Benth. Fl. Austral.* vii (1878) 762; *Thoms. N.Z. Ferns* (1882) 87; *Field N.Z. Ferns* (1890) 138, t. 22, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1010. Grammitis Billardieri *Willd. Sp. Plant.* v (1810) 139. G. australis *R. Br. Prodr.* (1810) 146; *A. Cunn. Precur.* (1836) n. 172; *Raoul Choix* (1846) 37; *Homb. et Jacq. Voy. au Pôle Sud* (1852) *Crypt.* t. 2G; *Hook. f. Fl. Antarct.* i (1844) 111; *Fl. Nov. Zel.* ii (1855) 44. G. rigida *and* G. humilis *Homb. et Jacq. l.c.* (1852) t. 2, F, H.

Var. **villosum** *Hook. f. Fl. Nov. Zel.* ii (1855) 44.—Stipes, margins, and undersurface of the fronds more or less villous with long spreading rufous or whitish hairs, often partially concealing the sori.—P. paradoxum *Col. in Trans. N.Z. Inst.* xiv (1882) 336. Grammitis ciliata *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 166.

Var. **pumilum** *Cheesem.*—Small, very densely matted; rhizomes stout, creeping, sometimes 1–2 in. long. Fronds ⅛–¾ in. long, obovate or spathulate, obtuse, narrowed to the base, very thick and coriaceous, glabrous or obscurely pubescent beneath. Sori usually solitary near the tip of the frond, large, roundish.—P. crassium *Kirk in Trans. N.Z. Inst.* xvii (1885) 232. Grammitis pumila *Armstr. in Trans. N.Z. Inst.* xiii (1879) 314. P. pumilum *Cockayne Bot. Stewart Is.* (1909) 47.

North and South Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island, Macquarie Island: The typical state and var. *villosum* not uncommon throughout on rocks or trunks of trees; var. *pumilum* in mountain districts from the East Cape southwards, ascending to over 5000 ft.

A very variable little plant, also found in Australia and Tasmania, South Africa, Chile, Fuegia, Tristan d'Acunha, and Marion Island.

2. **P. grammitidis** *R. Br. Prodr.* (1810) 147.—Rhizome short, tufted, crowned with subulate-lanceolate scales; roots long, fibrous. Stipes short, wiry, naked, 1–2 in. long. Fronds tufted at the top of the rhizome, very variable in size and shape, 3–9 in. long, 1–3 in. broad, lanceolate to oblong-lanceolate or narrow-ovate, acuminate, sometimes caudate, dark-green, coriaceous, quite glabrous, pinnatifid almost to the rhachis. Pinnae often unequal, linear, decurrent on the rhachis at the base and confluent; in large states 1–3 in. long, ⅙–⅓ in. broad, deeply lobed or pinnatifid; in small forms shorter, entire or sinuate or shortly lobed; rarely the pinnae are

reduced to short triangular lobes, so that the frond is narrow-linear in outline. Veins obscure, simple or forked. Sori oblong or rounded, usually one at the base of each segment of the pinnae, more rarely 2–4 to a segment.—*A. Cunn. Precur.* (1836) n. 177; *Raoul Choix* (1846) 37; *Hook. Sp. Fil.* iv (1862) 230; *Hook. f. Fl. Antarct.* i (1844) 111; *Fl. Nov. Zel.* ii (1855) 41; *Handb. N.Z. Fl.* (1864) 380; *Hook. and Bak. Syn. Fil.* (1873) 327; *Benth. Fl. Austral.* vii (1878) 764; *Thoms. N.Z. Ferns* (1882) 88; *Field N.Z. Ferns* (1890) 139, t. 14, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1011. Grammitis heterophylla *Labill. Pl. Nov. Holl.* ii (1806) 90, t. 239.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands: From the North Cape southwards, abundant in forests on the trunks of trees, more rarely on rocks. Sea-level to 3500 ft.

Also in Tasmania and Victoria.

3. **P. dictyopteris** *Metten. in. Ann. Sci. Nat.* xv (1861) 72.—Rhizome small, short, knot-like, densely clothed with brownish lanceolate scales, emitting woolly rootlets, some of which creep and produce new tufts of fronds. Fronds tufted at the top of the rhizome, 4–12 in. long, $\frac{2}{3}$–$\frac{3}{4}$ in. broad, lanceolate or linear-lanceolate, acuminate, very gradually narrowed to the base or to a short stipes, quite entire, bright-green, rather fleshy but hardly coriaceous, quite glabrous; midrib stout, evident. Veins hidden in the substance of the frond, anastomosing, forming elongated hexagonal areoles without included free veinlets. Sori large, broadly oblong or rounded, prominent, rather far apart, in a single row on each side of the frond, nearer the midrib than the margin.—P. Cunninghamii *Hook. Sp. Fil.* v (1864) 58; *Hook. f. Handb. N.Z. Fl.* (1864) 381; *Hook. and Bak. Syn. Fil.* (1873) 354; *Thoms. N.Z. Ferns* (1882) 89; *Field N.Z. Ferns* (1890) 141, t. 15, f. 5; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 246. P. attenuatum *A. Rich. Fl. Nouv. Zel.* (1832) 62; *A. Cunn. Precur.* (1836) n. 173; *Raoul Choix* (1846) 37; *Hook. Ic. Plant.* (1842) t. 409 (*not of R. Br.*). Dictymia lanceolata *J. Smith in Bot. Mag.* 72, *Comp.* (1846) 16; *Hook. f. Fl. Nov. Zel.* ii (1855) 43. Dictyopteris lanceolata *J. Smith Gen. Ferns.*

North Island: In forests from the North Cape to Cook Strait, not uncommon, usually on the trunks of trees or on rocks. South Island: Nelson–Maitai Valley, *T. F. C.* Marlborough—*Buchanan.* Canterbury—Akaroa, *Raoul.* Sea-level to 2500 ft.

Also in the New Hebrides. I have seen no specimens from the south of Nelson. Mr. Phillips Turner sends me a curious crested form obtained near Wellington.

4. **P. pustulatum** *Forst. f. Prodr.* (1786) n. 436.—Rhizome very long, much branched, climbing up the trunks of trees or over rocks, everywhere clothed with squarrose linear-subulate dark-brown scales. Stipites scattered along the rhizome, 2–4 in. long, firm, slender, glabrous. Fronds very variable in size and outline, dark-green, thin and membranous, quite glabrous, sometimes 3–9 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, linear-lanceolate, acuminate, gradually narrowed into the stipes, quite entire; at other times 6–18 in. long, 2–6 in. broad, cut down to a broadly winged rhachis into few or many linear-lanceolate acuminate segments; segments rather distant, 1–3 in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, straight or falcate. Veins not very distinct, anastomosing, forming large irregular areoles with included free veinlets. Sori rather small, distant, broadly oblong or rounded, forming a row parallel with the margin and just within it, sunk in a shallow cavity of the frond and thus forming a pustule on the upper surface.—*A. Cunn. Precur.* (1836) n. 175;

Raoul Choix (1846) 37 ; *Hook. Sp. Fil.* v (1864) 80 ; *Hook. f. Handb. N.Z. Fl.* (1864) 382 ; *Hook. and Bak. Syn. Fil.* (1873) 363 ; *Thoms. N.Z. Ferns* (1882) 89 ; *Field N.Z. Ferns* (1890) 141, t. 17, f. 2 ; *Cheesem. Man. N.Z. Fl.* (1906) 1013. P. scandens *Forst. f. Prodr.* (1786) n. 437 ; *Benth. Fl. Austral.* vii (1878) 770. Phymatodes pustulata *Presl Tent. Pterid.* (1836) 196 ; *Hook. f. Fl. Nov. Zel.* ii (1855) 42. Pleopeltis pustulata *Moore Ind. Fil.* (1857) 78.

North and South Islands, Chatham Islands : Abundant in woods from the North Cape to Nelson, Marlborough, and Westland, from thence less common to the south of Otago. Sea-level to 2500 ft.

Found also in eastern Australia, from Queensland to Victoria, and in Norfolk Island. The fronds are fragrant when freshly dried, and were formerly used by the Maoris for scenting oil for applying to the person. Mr. Carruthers (Fl. Vitiensis, 369) considers that this is Forster's *P. scandens*, and that his *P. pustulatum* is the same as *P. diversifolium*.

5. **P. diversifolium** *Willd. Sp. Plant.* v (1810) 166.—Rhizome long, stout, creeping, often glaucous, clothed with appressed ovate-lanceolate acuminate scales, which are dark-brown or almost black with usually a pale scarious margin. Stipes jointed on to the rhizome, 2–8 in. long, stout, firm, erect, smooth and glossy, quite naked. Fronds numerous, scattered along the rhizome, bright-green, coriaceous, quite glabrous, polymorphous ; sometimes 3–9 in. long, ½–2 in. broad, lanceolate or ovate-lanceolate, entire ; at other times 6–18 in. long, 3–9 in. broad, deeply pinnatifid. Segments varying in number from 1 to 12 on a side, 1–5 in. long, ⅓–1¼ in. broad, oblong-lanceolate or linear, usually acuminate, confluent at the base with the broadly winged rhachis. Veins conspicuous, the primary ones irregular, enclosing between them several areoles with free included veinlets. Sori numerous, large, orbicular, forming a single row on each side of the midrib, medial or rather nearer the margin than the midrib.—*P. Billardieri R. Br. Prodr.* (1810) 147 ; *A. Cunn. Precur.* (1836) n. 174 ; *Raoul Choix* (1846) 37 ; *Hook. Sp. Fil.* v (1864) 82 ; *Hook. and Bak. Syn. Fil.* (1873) 364 ; *Thoms. N.Z. Ferns* (1882) 90 ; *Field N.Z. Ferns* (1890) 141, t. 2, f. 4 ; *Cheesem. Man. N.Z. Fl.* (1906) 1013. P. Phymatodes *A. Rich. Fl. Nouv. Zel.* (1832) 66 (*not of Linn.*). P. scandens *Labill. Pl. Nov. Holl.* ii (1806) 91, t. 240 (*not of Forst. f.*). Phymatodes Billardieri *Presl Tent. Pterid.* (1836) 196 ; *Hook. f. Fl. Antarct.* i (1844) 111 ; *Fl. Nov. Zel.* ii (1855) 42.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands : Abundant throughout, usually on trees or rocks, but sometimes on the ground. Sea-level to 3000 ft.

Found also in Norfolk Island, Lord Howe Island, New Caledonia, Australia, and Tasmania, and very closely allied to the tropical *P. Phymatodes* Linn.

6. **P. novae-zealandiae** *Bak. in Hook. Ic. Plant.* t. 1674.—Rhizome long, stout, woody, as thick as the finger, densely clothed with large tawny ovate-lanceolate scales. Stipes 6–12 in. long, firm, erect, pale-brown, shining, quite naked. Fronds scattered along the rhizome, large, 1–4 ft. long, 6–14 in. broad, oblong-lanceolate, acuminate, thinly coriaceous, dark-green, quite glabrous, deeply pinnatifid or almost pinnate at the base ; rhachis narrowly winged. Segments (or pinnae) 8–20 pairs, opposite or nearly so, ascending, 4–8 in. long, about ½ in. broad, linear-lanceolate, acuminate, quite entire or obscurely sinuate, the lower ones sometimes narrowed

towards the base. Veins indistinct, copiously anastomosing; areoles rather large with included free veinlets. Sori large, globose, forming a single row on each side of the midrib, rather nearer the margin than the midrib.—*Ann. Bot.* v (1891) 479; *Thoms. N.Z. Ferns* (1882) 90; *Field N.Z. Ferns* (1890) 142, t. 27, f. 3; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 247.

North Island: Te Aroha, Pirongia, and Karioi Mountains, *T. F. C.;* Lake Waikaremoana, *A. Hamilton!* Waimarino Forest, *R. Curtis! T. F. C.;* forest to the west of Ruapehu, *H. C. Field! T. F. C., Cockayne.* Usually on logs or climbing up trees, rarely on the ground. 1500–3000 ft.

Apparently confined to the forest country in the central portions of the North Island. Closely allied to *P. diversifolium*, but the rhizome is much stouter, and densely clothed with shaggy spreading scales; the fronds are larger, often 4 ft. long, and more deeply pinnatifid; the segments are more numerous, longer and narrower; the venation is not so distinct, and the texture thinner. There is also no tendency to the polymorphism of the fronds so noticeable in both *P. diversifolium* and *P. pustulatum*, and simple fronds are apparently unknown.

32. **CYCLOPHORUS** Desv.

Rhizome long and creeping, or short and tufted. Stipes jointed on to the rhizome, not continuous with it. Fronds in the majority of the species simple and entire, often dimorphous, usually covered with a densely felted tomentum composed of star-like hairs carried at the top of a jointed stalk. Veins often buried in the substance of the frond, when visible copiously anastomosing. Sori numerous, dorsal, globose or oblong, irregularly placed, often covering the whole of the under-surface of the upper part of the frond. Sporangia stalked, girt by an incomplete vertical ring, bursting transversely.

A genus of about 50 species, mostly tropical, and best developed in Indo-Malaya, Melanesia, and Polynesia. There is little to separate it from *Polypodium* except the felted tomentum of star-shaped hairs.

1. **C. serpens** *C. Christen. Ind. Fil.* (1905) 201. — Rhizome long, creeping, branched, climbing up the trunks of trees or over rocks, clothed with lanceolate long-acuminate ferruginous scales. Stipites remote, ½–3 in. long, firm, erect, jointed on the top of a scaly prolongation of the rhizome. Fronds dimorphous, simple, entire or obscurely sinuate, very thick and coriaceous, dark-green or yellow-green, glabrous or nearly so above, beneath densely clothed with whitish or buff-coloured stellate scales; sterile fronds variable in size and shape, 1–3 or even 4 in. long, ½–1 in. broad, obovate-spathulate or elliptical-spathulate to nearly orbicular, obtuse; fertile longer and narrower, 2–6 in. long, ½–¾ in. broad, linear-oblong or linear-lanceolate, obtuse or subacute, gradually tapering into the stipes. Veins quite hidden in the substance of the frond, copiously anastomosing. Sori very copious, irregularly scattered, large, prominent, often confined to the upper part of the frond, usually confluent in age.—Polypodum serpens *Forst. f. Prodr.* (1786) n. 435; *Hook. and Bak. Syn. Fil.* (1873) 349; *Benth. Fl. Austral.* vii (1878) 767; *Thoms. N.Z. Ferns* (1882) 89; *Field N.Z. Ferns* (1890) 140, t. 6, f. 9; *Cheesem. Man. N.Z. Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands : Abundant throughout. Sea-level to 3500 ft.

Plentiful in eastern Australia, also found in Norfolk Island and several of the Pacific islands.

33. **GLEICHENIA** Smith.

Rhizome long, creeping, rigid and wiry, often clothed with chaffy scales. Stipes tall, erect or scrambling, usually rather slender. Fronds once or several times dichotomously forked, usually with a terminal bud in the fork, the divisions often spreading in a horizontal plane, ultimate branches pinnately divided. Segments of the pinnae rather small and broadly ovate or suborbicular, or larger and oblong to linear-lanceolate. Veins free. Sori dorsal, placed on the fork or at the tip of an exterior veinlet, of 2–12 sporangia. Indusium wanting. Sporangia sessile, splitting vertically, completely surrounded by a broad transverse ring.

Species between 50 and 60, chiefly tropical, but one species extends as far north as Japan, and 5 are found in New Zealand. Of these, 1 is widely spread in hot countries, 3 extend to Australia and New Caledonia, the remaining 1 is endemic.

* Eugleichenia. *Segments of the pinnae small, suborbicular. Sori solitary at the apex of a veinlet.*

Segments of the pinnae flat or slightly recurved. Sporangia 2–4, near the upper inner angle .. .. 1. *G. circinata.*

Segments of the pinnae with their margins incurved almost to the rhachis, hence pouch-shaped. Sporangia usually 2 .. 2. *G. dicarpa.*

** Mertensia. *Segments of the pinnae linear or linear-oblong, much larger than in the previous section. Sori near the middle or at the fork of a veinlet.*

† No accessory pinnae at the base of the lower forks of the frond.

Fronds umbrella-shaped, rigid and coriaceous. Segments of the pinnae entire, glaucous beneath. Sporangia 2–5 .. .. 3. *G. Cunninghamii.*

Fronds fan-shaped, submembranous. Segments of the pinnae serrulate, green on both surfaces. Sporangia 3–5 .. .. 4. *G. flabellata.*

†† A pair of spreading or deflexed accessory pinnae at the base of the lower forks of the frond.

Fronds repeatedly dichotomous, the ultimate branches ending in a pair of pinnae 3–12 in. long. Pinnulēs lanceolate, obtuse, glaucous beneath. Sporangia 6–12 .. .. .. 5. *G. linearis.*

1. **G. circinata** *Swartz Syn. Fil.* (1806) 165.—Very variable in size and mode of growth, sometimes stiff, erect, 1–3 ft. high ; sometimes weak and scrambling among other vegetation and attaining a length of 3–5 ft. or more. Rhizome long, slender, wiry, often much branched, more or less clothed with reddish-brown fimbriate scales. Stipes smooth, slender, cylindrical, glabrous or more or less densely scaly and woolly. Fronds usually repeatedly dichotomous and proliferous from the lower axils ; branches zigzag, spreading, often interlaced ; rhachides generally clothed with rusty-red stellate hairs often mixed with fimbriate scales, rarely glabrous. Pinnae numerous along the branches, spreading, $\frac{1}{2}$–2 in. long, $\frac{1}{12}$–$\frac{1}{6}$ in. broad, narrow-linear, uniformly pinnatifid to the base. Segments

T.N.Z.I. Vol. 56, p. 83.

Gleichenia.

"1. G. circinata Sw. (1806), not authors. Syn. G. dicarpa R.Br. (1810).
2. G. microphylla R. Br. (1810). Syn. G. circinata of authors.

"Yours series should thus be named--

1. G. circinata with its var. hecistophylla.
2. G. microphylla (G. circinata of yours).

"May G. alpina be maintained as a distinct species?" (C.C.)

small, suborbicular, coriaceous, convex above, the margins so much recurved beneath that the segment is cucullate or pouch-shaped, usually clothed with woolly hairs beneath. Sori one to each segment, just visible in the pocket-like cavity of the segment, or concealed by woolly hairs; sporangia 1–2, rarely more.—*Hook. Sp. Fil.* i (1846) 3, t. 1c; *Hook. f. Fl. Nov. Zel.* ii (1855) 5; *Handb. N.Z. Fl.* (1864) 348; *Benth. Fl. Austral.* vii (1878) 698; *Hook. and Bak. Syn. Fil.* (1873) 12; *Thoms. N.Z. Ferns* (1882) 25; *Field N.Z. Ferns* (1890) 37, t. 3, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1018.

Var. **hecistophylla.**—Usually 1–3 ft. high. Frond much and closely dichotomously branched, usually spreading in a horizontal plane; stipes and rhachis densely woolly and scaly. Segments strongly incurved beneath, sometimes as much as in the typical form, but variable in this respect.—G. hecistophylla *A. Cunn. Precur.* (1836) n. 163; *Hook. Sp. Fil.* i (1846) 4, t. 2B. G. semi-vestita *var.* hecistophylla *Hook. f. Fl. Nov. Zel.* ii (1855) 5. G. circinata *var.* hecistophylla *Hook. f. Handb. N.Z. Fl.* (1864) 348.

Var. **alpina** *Hook. f. Fl. Tasm.* ii (1860) 131.—Smaller and more compactly tufted, 2–12 in. high; rhachis, young shoots, and under-surface of segments densely clothed with ferruginous wool mixed with scales. Fronds much smaller and more sparingly divided.—*Handb. N.Z. Fl.* (1864) 348; *Benth. Fl. Austral.* vii (1878) 698. G. alpina *R. Br. Prodr.* (1810) 161; *Hook. and Grev. Ic. Fil.* (1829) t. 58; *Hook. Sp. Fil.* i (1846) 2.

North and South Islands, Stewart Island, Chatham Islands: Var. *hecistophylla* abundant in swampy places on poor soils in the North Island, local elsewhere. Sea-level to 2000 ft. Var. *alpina:* Mountainous localities from Moehau (Cape Colville) and Rotorua southwards, ascending to 4500 ft.

See. B. Mus. occas. papers. Vol. XVII : 79–84, 1942.

numerous, closely placed, broadly ovate or orbicular, obtuse, adnate by a broad base, flat or concave beneath, not cucullate nor pouch-shaped, coriaceous or almost membranous, green or glaucous beneath, glabrous or the costa more or less woolly and chaffy. Veins pinnately branched. Sori solitary in the segments, placed at the tip of the exterior veinlet near the upper angle of the segment, of 2–4 sporangia.—*Hook. and Bak. Syn. Fil.* (1873) 11 ; *Hook. f. Handb. N.Z. Fl.* (1864) 347 (*excl. var.* hecistophylla) ; *Benth. Fl. Austral.* vii (1878) 697 ; *Thoms. N.Z. Ferns* (1882) 25 ; *Field N.Z. Ferns* (1890) 36, t. 2, f. 2 ; *Cheesem. Man. N.Z. Fl.* (1906) 1017. G. semi-vestita *Labill. Sert. Nov. Cal.* (1824) 8, t. 11 ; *Hook. Sp. Fil.* i (1846) 3, t. 2A ; *Hook. f. Fl. Nov. Zel.* ii (1855) 5 (*excl. var.* hecistophylla). G. microphylla *R. Br. Prodr.* (1910) 161. G. speluncae *R. Br. Prodr.* (1810) 160. G. punctulata *Col. in Trans. N.Z. Inst.* xvi (1884) 344. G. patens *Col. in Trans. N.Z. Inst.* xx (1888) 212.

North and South Islands, Stewart Island : From the North Cape southwards, plentiful in the North Island, but rare and local to the south of Cook Strait. Sea-level to 2000 ft. *Waewaekaka ; Waewaematuku.*

Common in Australia, also extending to New Caledonia and Malaya. Mr. Colenso's *G. patens* is an excessively proliferous state with slender almost subscandent stems, forming large masses in heated soil near hot springs at Taupo. The fronds are more membranous than usual, but that and its other peculiarities are easily accounted for by the exceptional nature of its habitat.

2. **G. dicarpa** *R. Br. Prodr.* (1810) 161.—Very similar to *G. circinata* in habit and mode of growth, but smaller, 1–2½ ft. high. Rhizome slender, wiry, usually clothed with chaffy scales. Stipes smooth, slender, glabrous or scaly-hispid. Fronds several times dichotomous, usually proliferous ; branches spreading in a horizontal plane, often interlaced ; rhachides scaly and hairy or sometimes almost glabrous. Pinnae numerous along the branches, spreading, ½–1¼ in. long, $\frac{1}{25}$–$\frac{1}{10}$ in. broad, very narrow-linear, deeply and uniformly pinnatifid. Segments numerous, closely placed, small, suborbicular, coriaceous, convex above, the margins so much recurved beneath that the segment is cucullate or pouch-shaped, usually clothed with woolly hairs beneath. Sori one to each segment, just visible in the pocket-like cavity of the segment, or concealed by woolly hairs ; sporangia 1–2, rarely more.—*Hook. Sp. Fil.* i (1846) 3, t. 1C ; *Hook. f. Fl. Nov. Zel.* ii (1855) 5 ; *Handb. N.Z. Fl.* (1864) 348 ; *Benth. Fl. Austral.* vii (1878) 698 ; *Hook. and Bak. Syn. Fil.* (1873) 12 ; *Thoms. N.Z. Ferns* (1882) 25 ; *Field N.Z. Ferns* (1890) 37, t. 3, f. 1 ; *Cheesem. Man. N.Z. Fl.* (1906) 1018.

(A. Cunn.) Hook. f.

Var. **hecistophylla.** — Usually 1–3 ft. high. Frond much and closely dichotomously branched, usually spreading in a horizontal plane ; stipes and rhachis densely woolly and scaly. Segments strongly incurved beneath, sometimes as much as in the typical form, but variable in this respect.—G. hecistophylla *A. Cunn. Precur.* (1836) n. 163 ; *Hook. Sp. Fil.* i (1846) 4, t. 2B. G. semi-vestita *var.* hecistophylla *Hook. f. Fl. Nov. Zel.* ii (1855) 5. G. circinata *var.* hecistophylla *Hook. f. Handb. N.Z. Fl.* (1864) 348.

(A. Cunn.)

Var. **alpina** *Hook. f. Fl. Tasm.* ii (1860) 131.—Smaller and more compactly tufted, 2–12 in. high ; rhachis, young shoots, and under-surface of segments densely clothed with ferruginous wool mixed with scales. Fronds much smaller and more sparingly divided.—*Handb. N.Z. Fl.* (1864) 348 ; *Benth. Fl. Austral.* vii (1878) 698. G. alpina *R. Br. Prodr.* (1810) 161 ; *Hook. and Grev. Ic. Fil.* (1829) t. 58 ; *Hook. Sp. Fil.* i (1846) 2.

North and South Islands, Stewart Island, Chatham Islands : Var. *hecistophylla* abundant in swampy places on poor soils in the North Island, local elsewhere. Sea-level to 2000 ft. Var. *alpina :* Mountainous localities from Moehau (Cape Colville) and Rotorua southwards, ascending to 4500 ft.

As a species, *G. dicarpa* stands very near to *G. circinata*, principally differing in the smaller segments of the pinnae, which have their margins incurved almost to the costa, leaving only a narrow slit open, through which the sori are visible unless masked by the ferruginous tomentum. I have followed the "Synopsis Filicum" in placing Cunningham's *G. hecistophylla* under *G. dicarpa*, but it has equal claims to be included with *G. circinata*, which was the position given to it by Sir J. D. Hooker, both in the Flora and the Handbook. The late Baron Mueller justly observed (Veg. Chath. Isl. 63) that it obliterates the limits of the two species. The typical form of *G. dicarpa* occurs in eastern Australia, New Caledonia, and Malaya, and var. *alpina* in Tasmania.

3. **G. Cunninghamii** *Heward ex Hook. Sp. Fil.* i (1846) 6, t. 6B.—Usually from 1–3 ft. high, but taller plants are sometimes seen. Rhizome long, branched, creeping, stout and woody, clothed with red-brown lanceolate scales. Stipes stout, erect, grooved down one side, in the young state densely clothed with large deciduous scales, becoming almost glabrous when old. Fronds several times dichotomously branched, the branches usually spreading all round in a horizontal plane and forming an umbrella-like top to the stipes, in large specimens proliferous from the centre, so that frequently there are 2–4 superposed tiers of branches. Ultimate branches or pinnae 3–12 in. long, $\frac{1}{2}$–$1\frac{1}{4}$ in. broad, linear-lanceolate, acuminate, deeply pectinate-pinnatifid above, pinnate below; rhachis usually clothed with deciduous scales and pilose. Segments $\frac{1}{3}$–$\frac{2}{3}$ in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, linear, straight or often falcate, acute, quite entire, coriaceous, dark-green and glabrous above, glaucous and usually pilose beneath; margins flat or recurved. Transverse veins numerous, forked near the base. Sori copious, solitary on one of the veinlets, of 2–5 sporangia.—*Hook. f. Fl. Nov. Zel.* ii (1855) 6, t. 71; *Handb. N.Z. Fl.* (1864) 348; *Hook. and Bak. Syn. Fil.* (1873) 13; *Thoms. N.Z. Ferns* (1882) 26; *Field N.Z. Ferns* (1890) 39, t. 7, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1019. G. ciliata *Col. in Trans. N.Z. Inst.* xxix (1897) 414.

North and South Islands, Stewart Island: In forests from the North Cape southwards, abundant in the North Island, local to the south of Cook Strait. Sea-level to 4000 ft. *Umbrella Fern; Tapuwaekotuku.*

Allied to *G. flabellata*, but the fronds spread in a horizontal plane, and are much more rigid and coriaceous, and the segments are shorter and narrower, quite entire, and glaucous beneath. It appears to be confined to New Zealand.

4. **G. flabellata** *R. Br. Prodr.* (1810) 161.—From 1–4 ft. high. Rhizome long, stout, branched, more or less clothed with reddish-brown laciniate scales. Stipes erect, cylindrical below, subcompressed above, slightly scaly or almost glabrous. Fronds several times dichotomously branched, ascending and fan-shaped, not spreading in a horizontal plane, often proliferous from the lower forks, so that there are sometimes 2–3 tiers of superposed branches. Ultimate branches or pinnae 4–12 in. long, 1–2 in. broad, lanceolate, acuminate or caudate, deeply pectinate-pinnatifid or pinnate towards the base. Segments close-set, ascending, $\frac{1}{2}$–1 in. long, narrow-linear, subacute, serrulate towards the tip, dilated at the base, green on both surfaces, glabrous above, often more or less scaly-pubescent beneath. Transverse veins numerous, forked near the base. Sori copious, solitary on one of the veinlets, of 3–5 sporangia.—*A. Cunn. Precur.* (1836) n. 164; *Raoul Choix* (1846) 37; *Hook. Sp. Fil.* i (1846) 6; *Fil. Exot.* (1857–59) t. 71; *Hook. f. Fl. Nov. Zel.* ii (1855) 6; *Handb. N.Z. Fl.* (1864) 348; *Hook. and Bak. Syn. Fil.* (1873) 12; *Benth. Fl. Austral.* vii (1878) 698; *Thoms. N.Z. Ferns* (1882) 26; *Field N.Z. Ferns* (1890) 41, t. 8, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1020. G. littoralis *Col. in Trans. N.Z. Inst.* xvi (1884) 344.

North Island: Auckland—Not uncommon by the side of streams, &c., from the North Cape to the Bay of Islands and Great Barrier Island, rare and local southwards to the Kauaeranga River (Thames) and the Manukau Harbour.

Also in Australia, ranging from Queensland to Tasmania, and in New Caledonia. Mr. Colenso's *G. littoralis* is certainly nothing more than a dwarf state, usually occurring near the sea.

5. **G. linearis** *C. B. Clarke in Trans. Linn. Soc.* i, 2d. series (1880) 428.—Usually from 2–4 ft. high, but sometimes dwarfed to a few inches, and occasionally reaching 6 ft. Rhizome long, slender, clothed with narrow reddish-brown bristly scales. Stipes slender, smooth and polished. Fronds repeatedly dichotomous or trichotomous, the ultimate branches ending in a pair of pinnae 3–12 in. long; a pair of smaller spreading or deflexed pinnae is also placed at the base of the lower forks. Pinnae lanceolate, acuminate, pinnatifid almost to the base. Segments close, spreading, ½–1 in. long, linear, entire, obtuse or emarginate, glaucous beneath and sometimes pubescent on the costa, firm or more or less membranous, pale-green. Veins transversely spreading from the costa, each one pinnately divided from near the base into 3–6 veinlets. Sori solitary on an exterior veinlet, of 6–12 sporangia.—*Hook. Sp. Fil.* i (1846) 12; *Hook. and Bak. Syn. Fil.* (1873) 15; *Hook. f. Handb. N.Z. Fl.* (1864) 747; *Benth. Fl. Austral.* vii (1878) 698; *Thoms. N.Z. Ferns* (1882) 27; *Field N.Z. Ferns* (1890) 39, t. 4, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1020. G. Hermanni *R. Br. Prodr.* (1810) 161. Mertensia dichotoma *Willd. in Vet. Akad. Handb.* (1804) 167. Polypodium dichotomum *Thunb. Fl. Jap.* (1784) 338, t. 37. Polypodium lineare *Burm. Fl. Ind.* (1768) 235, t. 67.

North Island: Auckland—In heated soil near hot springs; Rotomahana, *Captain G. Mair! T. Kirk!* (in this locality destroyed by the eruption of Tarawera in 1886); Otumakokori and Orakeikorako, *T. Kirk! T. F. C.;* Karapiti, *Hochstetter;* Wairakei, *Norton! Field, T. F. C.;* hot springs near Matata, *Captain G. Mair.* Sea-level to 1600 ft.

Almost universal in tropical and subtropical countries. Forster, in his "Esculent Plants" (p. 75), recorded it as a native of New Zealand, and stated that the roots were eaten by the Natives; but as he only collected in the South Island it is extremely improbable that he ever saw it in New Zealand, and there is no other record of the roots being eaten.

34. **SCHIZAEA** Smith.

Rhizome short, thick, creeping. Stipes rigid, wiry, erect. Fronds simple or forked or dichotomously branched, flat or terete, very narrow, without expanded laminae. Sori on the under-surface of fertile segments terminating the frond or its branches, each segment consisting of a number of crowded linear pinnae, those of the opposite sides being usually applied to one another so as to conceal the under-surface. Sporangia ovoid, sessile, splitting vertically, crowned by a complete transverse ring, arranged in 2 or rarely 4 rows on the under-surface of the pinnae of the fertile segments.

A small genus of about 25 species, dispersed through the tropical or warm temperate regions of both hemispheres. Two of the New Zealand species are widely distributed; the third extends to Australia alone.

Fronds smooth, terete or nearly so, undivided .. .. .. 1. *S. fistulosa.*

Fronds scabrous, terete or obscurely compressed, forked or rarely twice or three times forked .. .. 2. *S. bifida.*

Fronds smooth, compressed, repeatedly dichotomously forked, flabellate .. .. 3. *S. dichotoma.*

1. **S. fistulosa** *Labill. Pl. Nov. Holl.* ii (1806) 103, t. 250.—Rhizome short, thick, creeping, clothed with dark chestnut-brown linear scales. Fronds numerous towards the end of the rhizome, not distinct from the stipes, dark-brown below, greenish-brown above, 4–12 in. long, $\frac{1}{40}$ in. broad, filiform, erect or flexuous, rigid, wiry, terete, grooved down the face, unbranched. Fertile segment terminating the frond, $\frac{1}{2}$–1 in. long, erect or suberect, consisting of 10–20 closely placed pinnae on each side; pinnae all pointing in one direction, $\frac{1}{8}$–$\frac{1}{4}$ in. long, linear, incurved at the tip; margins denticulate or fringed. Sporangia in 2 closely placed rows, covering the whole of the under-surface.—*Hook. f. Handb. N.Z. Fl.* (1864) 749; *Hook. and Bak. Syn. Fil.* (1873) 429; *Benth. Fl. Austral* vii (1878) 693; *Thoms. N.Z. Ferns* (1882) 95; *Field N.Z. Ferns* (1890) 150, t. 14, f. 5; *Cheesem. Man. N.Z. Fl.* (1906) 1021. S. propinqua *A. Cunn. Precur.* (1836) n. 168.

Var. **australis** *Hook. f. Handb. N.Z. Fl.* (1864) 749.—Smaller, 1–3 in. high; rhizome stouter in proportion. Fertile segment $\frac{1}{4}$–$\frac{1}{3}$ in. long, of 6–8 pairs of pinnae. S. australis *Gaud. Fl. Ins. Mal.* (1825) 98; *Hook. f. Fl. Antarct.* i (1844) 111; *Hook. and Bak. Syn. Fil.* (1873) 428; *Thoms. N.Z. Ferns* (1882) 95. S. palmata *Homb. et Jacq. Voy. au Pôle Sud.* ii (1853) *Crypt.* 82, t. z.

North and South Islands, Chatham Islands, Auckland Islands: The typical form not uncommon in barren clay soils throughout the North Island, apparently rare and local to the south of Cook Strait. Var. *australis*: Cold peaty localities in mountain districts from Moehau (Cape Colville) southwards, descending to sea-level in Stewart Island and the Auckland Islands. Sea-level to 4000 ft.

Also in Australia and Tasmania, New Caledonia, Madagascar, Chile, and the Falkland Islands. *S. australis* is clearly only a depauperated form, connected with the type by transitional stages.

2. **S. bifida** *Willd. in Akad. Wiss. Erf.* i (1802) 30, t. 3.—Rhizome very short, stout, creeping. Fronds close together along the rhizome, not distinct from the stipes, 6–12 in. high or more, about $\frac{1}{30}$ in. diam., rigid, erect, wiry, more or less scabrous, somewhat flattened, with a prominent midrib and narrow thick wing on each side, usually forked at or below the middle, rarely undivided, the branches sometimes forked a second or even a third time. Fertile segments terminating the branches, $\frac{1}{2}$–$\frac{3}{4}$ in. long, erect or slightly recurved, rather broader than in *S. fistulosa*, of 10–20 closely placed pinnae on each side. Pinnae all turned to the one side, $\frac{1}{6}$–$\frac{1}{3}$ in. long, linear, fringed with long cilia. Sporangia in 2 closely placed rows, rather smaller than in *S. fistulosa*.—*A. Rich. Fl. Nouv. Zel.* (1842) 95; *A. Cunn. Precur.* (1836) n. 169; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 47; *Handb. N.Z. Fl.* (1864) 385 (*in part*); *Hook. and Bak. Syn. Fil.* (1873) 429; *Benth. Fl. Austral.* vii (1878) 693; *Thoms. N.Z. Ferns* (1882) 96; *Field N.Z. Ferns* (1890) 151, t. 12, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1022.

North Island: On sterile clay or pumiceous soils from the North Cape to Cook Strait, but often local. South Island: Nelson—Takaka and Paramahoi, *Kingsley.* Sea-level to 2000 ft.

Also in Australia and Tasmania. Unbranched specimens are best distinguished from *S. fistulosa* by the scabrous frond and broader fertile segment.

3. **S. dichotoma** *Smith in Mem. Act. Turin.* v (1793) 422, t. 9.—Rhizome short, stout, creeping. Fronds few or many, close together, 6–14 in. long, erect, rigid, wiry; lower portion or stipes angular, channelled in front; upper portion repeatedly dichotomous, forming a flabellate or

deltoid frond 2–4 in. across or more; branches flattened, $\frac{1}{20}$–$\frac{1}{12}$ in. broad; midrib stout, evident; margins sometimes minutely toothed towards the tip. Fertile segments terminating the branches, distinctly stalked, erect or inclined, $\frac{1}{4}$–$\frac{1}{3}$ in. long, consisting of 4–10 spreading pinnae on each side; pinnae $\frac{1}{8}$–$\frac{1}{4}$ in. long, linear, fringed with long hairs. Sporangia in two closely placed rows.—*Hook. and Grev. Ic. Fil.* (1829) t. 17; *A. Cunn. Precur.* (1836) n. 170; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 47; *Handb. N.Z. Fl.* (1864) 385; *Hook. and Bak. Syn. Fil.* (1873) 430; *Benth. Fl. Austral.* vii (1878) 694; *Thoms. N.Z. Ferns* (1882) 96; *Field N.Z. Ferns* (1890) 151, t. 24, f. 2; *Cheesem. Man. N.Z. Fl.* (1906) 1022.

North Island: Auckland—In kauri forests from Kaitaia and Mangonui southwards to Tairua and the Lower Waikato, not common; in heated soil near hot springs at Orakeikorako, Upper Waikato, *T. Kirk, C. J. Norton!* Sea-level to 1500 ft.

A widely spread species, found in the tropical and warm temperate regions of both hemispheres, with the exception of the Continent of Africa. It has been recorded from Madagascar and the Mascarene Islands.

35. **LYGODIUM** Swartz.

Climbing ferns, with long twining stems, often ascending trees to a considerable height. Primary pinnae distant on the common rhachis or stem, and inserted on it by a short and often almost obsolete petiole, dichotomously divided; the secondary divisions divaricate, stalked, usually again dichotomous, or in species not found in New Zealand pinnately divided. Sterile pinnules ovate to oblong-lanceolate, ligulate; fertile usually much contracted and frequently copiously divided. Sporangia ovoid, obliquely sessile, splitting vertically, crowned by a complete transverse ring, arranged in two rows on the under-surface of the contracted fertile pinnules, or forming short spikes projecting from the margins of the leafy pinnules, each sporangium in the axil of a large scalelike indusium.

A very distinct genus of about 20 species, widely distributed in the tropics of both hemispheres. The single New Zealand species is endemic.

1. **L. articulatum** *A. Rich. Fl. Nouv. Zel.* (1832) 96, t. 15.—Rhizome slender, creeping, clothed with glossy chestnut-brown linear scales. Stipites very numerous, long, slender, climbing, reaching the tops of tall forest-trees, branched, wiry, often intertwined and forming almost impenetrable screens, quite smooth and glabrous. Primary pinnae dichotomously palmate-partite; primary petiole short, $\frac{1}{6}$–$\frac{1}{2}$ in. long; two secondary petioles widely diverging, 1 in. or more long, again twice forked; pinnules 2–4 in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, jointed at the base, ligulate-oblong or oblong-lanceolate, obtuse or subacute, thinly coriaceous, often glaucous beneath. Veins free. Fertile pinnae many times dichotomous, the ultimate pinnules small, much contracted, cuneate or flabellate, deeply lobed; the lobes ending in closely placed short spikelets, each with 8–12 sporangia on the under-surface.—*A. Cunn. Precur.* (1836) n. 167; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 47; *Handb. N.Z. Fl.* (1864) 385; *Hook. and Bak. Syn. Fil.* (1873) 437; *Thoms. N.Z. Ferns* (1882) 96; *Field N.Z. Ferns* (1890) 152, t. 22, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 1023; *Ill. N.Z. Fl.* (1914) t. 248. L. gracilescens *Col. in Trans. N.Z. Inst.* xxviii (1896) 620.

North Island: Auckland—In woods from the North Cape to the Bay of Plenty and Kawhia, abundant. Sea-level to 2500 ft. *Mange-mange.*

The tough and wiry twining stems were formerly twisted into ropes by the Maoris and used for securing the thatch on the roofs of their houses; and they were also employed for making eel-traps.

36. **TODEA** Willd.

Rhizome thick, stout, erect, often forming a caudex of enormous size. Fronds numerous at the top of the rhizome, erect, 2–6 ft. high, thick and coriaceous, quite opaque, 2-pinnate. Ultimate divisions firm, entire or serrate. Veins simple or forked. Sori on the under-surface of the frond, usually of many sporangia, placed on the lateral veinlets proceeding from the costa, often confluent. Sporangia almost round, splitting to the base into two valves, ring rudimentary.

A genus of a single species confined to South Africa, Australia, Tasmania, and the northern portion of New Zealand.

1. **T. barbara** *Moore Ind. Fil.* (1857) 119.—Rhizome stout, erect, sometimes forming a trunk as much as 4 ft. high and 2 ft. diam. Stipes 1–2 ft. long or more, stout, erect, quite smooth. Fronds 2–4 ft. long, 9–12 in. broad, oblong-lanceolate, acute, dark-green, coriaceous, opaque, quite glabrous, 2-pinnate. Primary pinnae numerous, close, erecto-patent, 4–10 in. long or more, ½–2 in. broad, lanceolate. Pinnules 1–1½ in. long, ⅙–¼ in. broad, linear or linear-lanceolate, acute, serrate, the uppermost confluent. Sori towards the base of the frond, usually occupying nearly the whole of the under-surface of the lower pinnules of the lower pimnae, the remainder of the frond sterile.—*Hook. and Bak. Syn. Fil.* (1873) 427; *Bot. Mag.* t. 5954; *Benth. Fl. Austral.* vii (1878) 699; *Thoms. N.Z. Ferns* (1882) 93; *Field N.Z. Ferns* (1890) 148, t. 26, f. 1; *Cheesem. Man. N.Z. Fl.* (1906) 1024. T. africana *Willd. in Schrift. Akad. Erf.* (1802) 14, t. 3, f. 1; *Hook. f. Fl. Nov. Zel.* ii (1855) 48 *and* 338; *Fl. Tasm.* ii (1860) 153, t. 178; *Handb. N.Z. Fl.* (1864) 384. Osmunda barbara *Thunb. Fl. Cap.* (1800) 171. Aerostichum barbarum *Linn. Sp. Plant.* ii (1753) 1072.

North Island: Auckland—Abundant in open gullies from the North Cape to Mangonui, and from thence more sparingly southwards to Whangaroa.

Also in Australia, from Queensland to Tasmania, and in South Africa. In Australia the rhizome is often enlarged into a short and massive trunk sometimes weighing as much as a ton and a half, but I have seen no New Zealand specimens as large.

37. **LEPTOPTERIS** Presl.

Rhizome stout, erect, sometimes forming a caudex of considerable size. Fronds tufted at the top of the rhizome, numerous, erect, 2–5 ft. high, always membranous and pellucid, dark-green, 2–3-pinnate; ultimate divisions small, cut into numerous linear lobes. Veins simple or forked, not anastomosing. Sori on the under-surface of the frond, usually of many sporangia, placed on the lateral veinlets proceeding from the costa. Sporangia short-stalked, splitting vertically; ring rudimentary, transverse.

A genus of 7 species, all very closely allied, ranging from New Zealand and Australia northwards to Fiji, New Caledonia, and New Guinea. It only differs from *Todea* in the delicately membranous texture of the frond, and in being much more finely divided. Both the New Zealand species are endemic.

Fronds 1–2 ft. long, truncate at the base, the lower pinnae not reduced in size .. .. 1. *L. hymenophylloides.*

Fronds 1½–4 ft. long, narrowed at the base, the lower pinnae gradually reduced in size .. .. 2. *L. superba.*

1. **L. hymenophylloides** *Presl Suppl. Tent. Pterid.* (1845) 71.—Rhizome stout, erect, often produced into a short thick caudex. Stipes 6–12 in. long, slender, wiry, erect, brownish-green, smooth and glabrous or more or less clothed with floccose tomentum. Fronds forming a crown at the top of the rhizome, 1–2½ ft. long, 6–12 in. broad, ovate-deltoid to lanceolate-deltoid, acuminate, truncate at the base, very thin and membranous, pellucid, dark-green, 3-pinnatifid; rhachis and costae more or less clothed with reddish-brown floccose hairs or nearly glabrous. Primary pinnae rather close, 3–6 in. long, ¾–1½ in. broad, lanceolate or oblong-lanceolate, acuminate, the lower ones not gradually reduced in size and becoming very small. Pinnules close-set, ½–¾ in. long, about ¼ in. broad, linear-oblong, deeply pinnatifid. Segments linear, erecto-patent, acute, entire or forked or sometimes trifid. Sporangia on the midrib of the segments, usually confined to the lower half.—*Hook. f. Fl. Nov. Zel.* ii (1855) 48; *Handb. N.Z. Fl.* (1864) 384. Todea hymenophylloides *A. Rich. Fl. Nouv. Zel.* (1832) 97, t. 16; *Hook. Gen. Fil.* (1842) t. 46B; *Garden Ferns* (1862) t. 54; *Hook. and Bak. Syn. Fil.* (1873) 427; *Thoms. N.Z. Ferns* (1882) 93; *Field N.Z. Ferns* (1890) 148, t. 4, f. 3; *Cheesem. Man. N.Z. Fl.* (1906) 1025. T. pellucida *Hook. and Grev. in Bot. Misc.* iii (1833) 232. T. marginata *Col. in Trans. N.Z. Inst.* xxix (1897) 419.

North and South Islands, Stewart Island: From the North Cape southwards, not uncommon in forest districts. Sea-level to 3000 ft.

Confined to New Zealand. A state with the pinnae rather more closely placed, and with the lower ones more or less reduced in size, approaches *T. superba*, and is often distinguished as var. *intermedia* by fern-collectors.

2. **L. superba** *Presl in Abh. Bohm.* v (1848) 326.—Rhizome stout, forming a thick erect caudex 1–3 ft. high, coated with densely matted fibrous rootlets. Stipes 1–4 in. long, stout, erect, more or less densely tomentose. Fronds forming a handsome spreading crown at the top of the rhizome, 1½–4 ft. long, 6–10 in. broad, lanceolate, acuminate, very gradually narrowed to the base, dark-green, thin and membranous, pellucid, 3-pinnatifid; rhachis stout, densely woolly-tomentose, as are the secondary rhachises. Primary pinnae very numerous, close-set, the longest ones about the middle of the frond, 3–6 in. long, ½–¾ in. broad, linear or linear-lanceolate, acuminate; the lower ones gradually diminishing in size, the lowermost minute. Pinnules very close, much overlapping, ¼–½ in. long, linear-oblong, pinnatifid almost to the base. Segments narrow-linear, simple or forked. Sporangia much as in *T. hymenophylloides.*—*Hook. Ic. Plant.* (1854) t. 910; *Hook. f. Fl. Nov. Zel.* ii (1855) 48; *Handb. N.Z. Fl.* (1864) 384. Todea superba *Col. in Tasm. Journ. Nat. Sci.* ii (1846) 138; *Hook. and Bak. Syn. Fil.* (1873) 428; *Thoms. N.Z. Ferns* (1882) 94; *Field N.Z. Ferns* (1890) 149, t. 21, f. 4; *Cheesem. Man. N.Z. Fl.* (1906) 1025, *and Ill. N.Z. Fl.* (1914) t. 249.

North and South Islands, Stewart Island: In dense moist forests from Te Aroha and Pirongia southwards, not uncommon, except in Marlborough, Canterbury, and the north of Otago, where it is rare and local. *Crape-fern; Prince of Wales's Feather.* Sea-level to 3500 ft.

Probably the most beautiful fern in New Zealand. It is closely allied to the preceding, and is connected with it by intermediate forms. Usually, however, it is readily distinguished by the larger and narrower frond, which tapers very gradually to the base, and by the closer and denser pinnules, which overlap considerably, the segments often turning up towards the upper side of the frond.

38. **MARATTIA** Smith.

Rhizome large, thick and swollen. Fronds numerous, large, 2–3-pinnate ; stipes stout, articulated at the base, and furnished with two adnate auricles. Veins all free. Sori oblong, placed at or near the tip of the veins, close to the margin of the pinnules, each sorus consisting of two parallel rows containing 4–12 sporangia, the sporangia of each row completely united into a boat-shaped mass called a synangium. Synangia coriaceous, the outer face smooth and convex, the inner flat and pierced by the narrow transverse slits of the dehiscent sporangia. Spores globose-tetrahedral.

A small genus of about 20 species, widely scattered through the tropical regions of both hemispheres and the warmer part of the South Temperate Zone. The single New Zealand species is found in Australia and Polynesia, South Africa, Malaya, Philippines, and India.

1. **M. fraxinea** *Smith Ic. Ined.* (1790) t. 48.—Rhizome a large irregularly shaped tuberous mass. Stipes stout, 1–2 ft. long or more, brownish-green, jointed at the base and furnished with large clasping auricles which are persistent on the rhizome. Fronds large, in fully grown specimens 6–12 ft. long, 2–5 ft. broad, ovate-deltoid, dark-green and glossy, coriaceous, 2-pinnate or rarely 3-pinnate. Primary pinnae 9 in. to 3 ft. long, often more than 1 ft. broad ; pinnules shortly stalked, 3–6 in. long, $\frac{1}{2}$–1 in. broad, lanceolate or oblong-lanceolate, acuminate, obliquely cuneate or rounded at the base ; margins minutely serrulate ; costa slightly scaly. Veins rather close, parallel, simple or sparingly forked. Sori oblong, brownish, $\frac{1}{10}$–$\frac{1}{8}$ in. long, on the veins just within the margin of the pinnules ; sporangia 8–12 to each synangium.—*Hook. and Bak. Syn. Fil.* (1873) 440 ; *Benth. Fl. Austral.* vii (1878) 695 ; *Thoms. N.Z. Ferns* (1882) 97 ; *Field N.Z. Ferns* (1890) 153, t. 25, f. 5 ; *Cheesem. Man. N.Z. Fl.* (1906) 1026. M. salicina *Smith in Rees Cyclop.* xxii (1802–20) 89 ; *Hook. f. Fl. Nov. Zel.* ii (1855) 49 ; *Handb. N.Z. Fl.* (1864) 386.

North Island : Lowland forests from Mangonui southwards to Cape Egmont and Waitotara, not common, usually in rich damp soils. *Para ; Parareka.* Sea-level to 1000 ft.

The large starchy rhizome was formerly eaten by the Maoris, and hence the plant was occasionally cultivated near their villages. It is now fast becoming rare.

39. **OPHIOGLOSSUM** Linn.

Rhizome usually short and suberect, sometimes slightly tuberous or nodose ; roots thick and fleshy, simple, sometimes giving rise to adventitious buds. Fronds solitary or 2–3 at the top of the rhizome, not circinate, stipitate, fleshy, composed of two portions ; one a leafy more or less expanded sterile lamina, with reticulated venation ; the other a narrow and much-contracted spike-like fertile part, which is inserted on the petiole or lamina of the sterile portion by a peduncle of variable length. Sporangia closely packed in 2 rows on the fertile spike and partly embedded in its tissue, globose, not annulate, dehiscing by a transverse slit ; spores numerous, tetrahedral.

A small genus, widely spread in both temperate and tropical regions. There is much uncertainty as to the limits of the species, which are estimated by some authors at 8–10 and by others (C. Christensen, for instance) at as many as 40. In the present work I have largely followed Prantl's latest arrangement, as far as the want of material allows me to do so.

1. **O. coriaceum** *A. Cunn. Precur.* (1836) n. 161.—Rhizome cylindric, suberect, slightly tuberous, roots fleshy. Fronds 1–2 (or rarely 3) from the rhizome, 1–3 in. long including the petiole and fertile spike; sterile lamina usually placed below the middle, $\frac{1}{4}$–2 in. long, $\frac{1}{6}$–$\frac{1}{3}$ in. broad, lanceolate to ovate-lanceolate, acute or obtuse or shortly apiculate, narrowed into a long cuneate base, fleshy or almost coriaceous; veins indistinct, reticulated in narrow areoles. Fertile spike $\frac{1}{4}$–$\frac{3}{4}$ in. long, on a slender peduncle which usually much exceeds the sterile lamina when mature. Sporangia 7–15 in each row.—*Presl Suppl.* (1845) 49; *Prantl Beit. Syst. Ophiog.* (1884) 314, t. 7, f. 9, 10, 11. O. gramineum *R. Br. Prodr.* (1810) 163 (*but not of Willd.*). O. lusitanicum *Hook. and Bak. Syn. Fil.* (1874) 445; *Thoms. N.Z. Ferns* (1882) 98; *Field N.Z. Ferns* (1890) 155, t. 21, f. 7 (*but not of Linn.*). O. vulgatum *vars.* gramineum, lusitanicum, *and* minimum *Hook. f. Fl. Nov. Zel.* i (1855) ii, 50; *Handb. N.Z. Fl.* (1864) 386. O. minimum *Col. ex Hook. and Bak.* (1874) 445. O. minimum *Armstr. in Trans. N.Z. Inst.* xiii (1881) 342.

Kermadec Islands, North and South Islands: Not uncommon in grassy places throughout, ascending to 3500 ft.

This, so far as New Zealand is concerned, consists of the varieties *gramineum*, *lusitanicum*, and *minimum* of the Flora and the Handbook. The two first are now considered to form a distinct species under Cunningham's name of *O. coriaceum*, of which Armstrong's *O. minimum* is probably a depauperated state. *O. coriaceum* is also known from Australia, Tasmania, Easter Island (Skottsberg), and Bolivia.

2. **O. pedunculosum** *Desv. in Berl. Mag.* v (1811) 306.—Rhizome short,

Ophioglossum Linn.

1. Rhizome slender, slightly tuberous, Blade slender; 1-2" long, $\frac{1}{8}$-$\frac{1}{2}$" wide. Spike $\frac{1}{4}$-$\frac{3}{4}$" long, no more. O. coriaceum.

2. Rhizome stouter. Blade often wide 1-$2\frac{1}{2}$" long, $\frac{1}{2}$-$1\frac{1}{2}$" wide. Spike $\frac{3}{4}$-$1\frac{1}{2}$" long. O. pedunculosum.

38. **MARATTIA** Smith.

Rhizome large, thick and swollen. Fronds numerous, large, 2–3-pinnate ; stipes stout, articulated at the base, and furnished with two adnate auricles. Veins all free. Sori oblong, placed at or near the tip of the veins, close to the margin of the pinnules, each sorus consisting of two parallel rows containing 4–12 sporangia, the sporangia of each row completely united into a boat-shaped mass called a synangium. Synangia coriaceous, the outer face smooth and convex, the inner flat and pierced by the narrow transverse slits of the dehiscent sporangia. Spores globose-tetrahedral.

A small genus of about 20 species, widely scattered through the tropical regions of both hemispheres and the warmer part of the South Temperate Zone. The single New Zealand species is found in Australia and Polynesia, South Africa, Malaya, Philippines, and India.

1. **M. fraxinea** *Smith Ic. Ined.* (1790) t. 48.—Rhizome a large irregularly shaped tuberous mass. Stipes stout, 1–2 ft. long or more, brownish-green, jointed at the base and furnished with large clasping auricles which are persistent on the rhizome. Fronds large, in fully grown specimens 6–12 ft. long, 2–5 ft. broad, ovate-deltoid, dark-green and glossy, coriaceous, 2-pinnate or rarely 3-pinnate. Primary pinnae 9 in. to 3 ft. long, often more than 1 ft. broad ; pinnules shortly stalked, 3–6 in. long, $\frac{1}{2}$–1 in. broad, lanceolate or oblong-lanceolate, acuminate, obliquely cuneate or rounded at the base ; margins minutely serrulate ; costa slightly scaly. Veins rather close, parallel, simple or sparingly forked. Sori oblong, brownish, $\frac{1}{1}$

1. **O. coriaceum** *A. Cunn. Precur.* (1836) n. 161.—Rhizome cylindric, suberect, slightly tuberous, roots fleshy. Fronds 1–2 (or rarely 3) from the rhizome, 1–3 in. long including the petiole and fertile spike; sterile lamina usually placed below the middle, $\frac{1}{4}$–2 in. long, $\frac{1}{6}$–$\frac{1}{3}$ in. broad, lanceolate to ovate-lanceolate, acute or obtuse or shortly apiculate, narrowed into a long cuneate base, fleshy or almost coriaceous; veins indistinct, reticulated in narrow areoles. Fertile spike $\frac{1}{4}$–$\frac{3}{4}$ in. long, on a slender peduncle which usually much exceeds the sterile lamina when mature. Sporangia 7–15 in each row.—*Presl Suppl.* (1845) 49; *Prantl Beit. Syst. Ophiog.* (1884) 314, t. 7, f. 9, 10, 11. O. gramineum *R. Br. Prodr.* (1810) 163 (*but not of Willd.*). O. lusitanicum *Hook. and Bak. Syn. Fil.* (1874) 445; *Thoms. N.Z. Ferns* (1882) 98; *Field N.Z. Ferns* (1890) 155, t. 21, f. 7 (*but not of Linn.*). O. vulgatum *vars.* gramineum, lusitanicum, *and* minimum *Hook. f. Fl. Nov. Zel.* i (1855) ii, 50; *Handb. N.Z. Fl.* (1864) 386. O. minimum *Col. ex Hook. and Bak.* (1874) 445. O. minimum *Armstr. in Trans. N.Z. Inst.* xiii (1881) 342.

Kermadec Islands, North and South Islands: Not uncommon in grassy places throughout, ascending to 3500 ft.

This, so far as New Zealand is concerned, consists of the varieties *gramineum*, *lusitanicum*, and *minimum* of the Flora and the Handbook. The two first are now considered to form a distinct species under Cunningham's name of *O. coriaceum*, of which Armstrong's *O. minimum* is probably a depauperated state. *O. coriaceum* is also known from Australia, Tasmania, Easter Island (Skottsberg), and Bolivia.

2. **O. pedunculosum** *Desv. in Berl. Mag.* v (1811) 306.—Rhizome short, cylindrical; roots long, fleshy. Fronds 1–2 from the rhizome, rarely more. Petiole above the ground; peduncle arising from the petiole; total length of frond, including the petiole and fertile spike, 4–12 in. Sterile lamina placed near the middle or slightly below it, $\frac{3}{4}$–3 in. long, $\frac{1}{2}$–1 in. broad, ovate or ovate-lanceolate or ovate-rhomboid, obtuse or subacute, truncate or broadly cuneate at the base, never cordate, rather fleshy, venation reticulated. Fertile spike $\frac{3}{4}$–$1\frac{1}{2}$ in. long on a slender peduncle inserted just below the sterile lamina and much overtopping it. Sporangia very variable in number, 15–40 in each row.—*Presl Suppl.* (1845) 54. O. elongatum *R. Cunn. in A. Cunn. Precur.* (1836) n. 161. O. vulgatum *Hook. f. Fl. Nov. Zel.* ii (1855) 50 (*not of Linn.*); *Handb. N.Z. Fl.* (1864) 386; *Hook. and Bak. Syn. Fil.* (1874) 445; *Thoms. N.Z. Ferns* (1882) 98; *Field N.Z. Ferns* (1890) 155, t. 21, f. 6. R. costatum *R. Br. Prodr.* (1810) 163.

North and South Islands, Chatham Islands: From the North Cape to Foveaux Strait, plentiful in moist grassy places, by the margins of swamps, &c. Sea-level to 2000 ft.

In the first edition of this work I followed Hooker and Baker in treating this plant as a form of the well-known *O. vulgatum;* but now most pteridologists split up that species into a considerable number of others with more restricted ranges. Most of the New Zealand forms agree with Cunningham's *O. elongatum*, which is now kept up as a distinct species by Christensen under the much older name of *O. pedunculosum* Desv., and which ranges from New Zealand and Australia northwards to Malaya, Ceylon, India, Philippines, and Japan.

40. **BOTRYCHIUM** Swartz.

Rhizome short, suberect, emitting numerous long fleshy branching roots. Fronds solitary or rarely two at the top of the rhizome, not circinate, stipitate, thick and fleshy, composed of two divisions: the posterior sterile,

pinnate or 2–3-pinnate or decompound; the anterior fertile, of numerous branched spikes forming a pedunculate panicle, the peduncle usually long, inserted on the petiole below the sterile lamina. Sporangia closely packed and sessile in two rows along the branches of the panicle, free, globose, not annulate, dehiscing by a transverse slit; spores numerous, tetrahedral.

Species variously estimated at from 10 to 30, according to the different views of authors. Found in most temperate or extratropical regions, rare in very hot climates. Both the New Zealand species are widely distributed.

Sterile segment of the frond simply pinnate; fertile bipinnate ..	1. *B. lunaria.*
Sterile and fertile segments both decompound	2. *B. australe.*

1. **B. lunaria** *Swartz Syn. Fil.* (1806) 110.—Rhizome short, tuberous. Fronds solitary at the top of the rhizome or rarely 2 together, 3–6 in. high; stipes stout, terete, glabrous, with 1 or 2 brownish sheathing scales at the base. Sterile lamina at about the middle of the frond, ¾–3 in. long, ½–1 in. broad, oblong or linear-oblong, rather fleshy, simply pinnate; pinnae 3–6 pairs, close-set, lunate or flabellate, entire or more or less deeply crenate-toothed. Veins flabellate, radiating from the base. Fertile segment equalling or exceeding the sterile, pedunculate, ½–3 in. long, lanceolate-deltoid, 2-pinnate; the divisions all turned to one side, narrow, thickly covered with the yellowish sporangia.—*Hook. f. Fl. Tasm.* ii (1860) 154; *Hook. and Bak. Syn. Fil.* (1873) 447; *Benth. Fl. Austral.* vii (1878) 690; *Enys in Trans. N.Z. Inst.* xvi (1884) 363; *T. Kirk l.c.* 366; *Field N.Z. Ferns* (1890) 166, t. 21, f. 8; *Cheesem. Man. N.Z. Fl.* (1906) 1028.

South Island: Canterbury—South-western slopes of Mount Torlesse, alt. 2700 ft., *J. D. Enys!*

Not uncommon in the temperate and cool mountainous portions of the Northern Hemisphere, and in Patagonia and Australia in the Southern. The few New Zealand specimens that I have seen are much under the average size of the species in Europe or North America, but I can see no other difference.

2. **B. australe** *R. Br. Prodr.* (1810) 164.—Rhizome short, stout, emitting numerous long and fleshy almost tuberous roots. Fronds solitary, 6–18 in. long or more. Stipes 1–3 in. long from the rhizome to the forking of the sterile and fertile segments, stout, thick and fleshy, terete. Sterile segment long-peduncled, variable in size, usually from 3–6 in. broad and long, but large specimens sometimes reach 9–12 in., and small ones are often dwarfed to less than 2 in., broadly deltoid, tripartite at the base, the divisions usually petiolate, 2–4-pinnate; the ultimate pinnules oblong or ovate, toothed or crenate or almost entire; texture thick and fleshy. Fertile segment on a stout or slender peduncle 4–12 in. long or more, usually overtopping the sterile segment; panicle 1½–6 in. long, nearly as broad at the base, much branched, 3–4-pinnate. Sporangia very numerous.—*A. Cunn. Precur.* (1836) n. 160; *Raoul Choix* (1846) 37; *Prantl Syst. Ophiogl.* (1883) 340. B. ternatum *Hook. and Bak. Syn. Fil.* (1873) 448; *Benth. Fl. Austral.* vii (1878) 690; *Thoms. N.Z. Ferns* (1882) 99; *Field N.Z. Ferns* (1890) 157, t. 20, f. 5, 5a; *Cheesem. Man. N.Z. Fl.* (1906) 1029 (*not of Thunb.*). B. virginianum *Hook. f. Fl. Nov. Zel.* ii (1855) 50 (*not of Swartz*). B. cicutarium *Hook. f. Handb. N.Z. Fl.* (1864) 387 (*not of Swartz*).

Var. **millefolium** *Prantl Syst. Ophiogl.* (1883) 341. — Frond more slender; sterile segment much more finely divided, the ultimate pinnules laciniately cut into narrow lobes and teeth. — B. biforme *Col. in Trans. N.Z. Inst.* xviii (1886) 223. B. cicutarium *var.* dissectum *Hook. f. Handb. N.Z. Fl.* (1864) (*not of Muhl.*).

North and South Islands, Chatham Islands: The ordinary form abundant from the North Cape to the south of Otago; var. *millefolium* often local. Sea-level to 3500 ft.

Also in Australia, Tasmania, and extratropical South America, and very closely allied to the northern *B. ternatum*, with which it was united by Hooker and Baker in the "Synopsis Filicum."

Family II. **MARSILEACEAE.**

Perennial plants, usually of small size, growing in marshes or in damp soil. Rhizome slender, creeping, rooting at the nodes. Leaves solitary or in tufts at the nodes of the rhizome, either filiform or of 4 leaflets borne at the top of a slender petiole. Sporocarps or conceptacles globose or oblong, on short peduncles which rise from the petioles or near their bases, each sporocarp containing numerous (*Marsilea*) or few (*Pilularia*) cavities or cells, and each cell containing a group or sorus composed of macrosporangia and microsporangia. Macrosporangia containing a single macrospore; microsporangia containing numerous microspores.

A small order of 2 genera and 50 or 60 species, found in most temperate and tropical countries. In germination a small female prothallium is developed within the macrospore, which eventually bursts, the prothallium protruding from the opening. A single archegonium is then formed on the prothallium, which is fertilized by spermatozoids set free by the bursting of the microspores, within which a rudimentary male prothallium bearing a single antheridium has been developed.

1. **PILULARIA** Linn.

Rhizome long, filiform, creeping and rooting. Leaves solitary at the nodes of the rhizome, circinate in vernation, filiform, erect. Sporocarps on short peduncles, globose, 2–4-celled, splitting at the top into as many valves as cells; each cell with a longitudinal parietal placenta bearing in the upper portion microsporangia containing numerous microspores, and below these few or many macrosporangia containing a solitary macrospore.

A small genus of 6 species, found in the temperate or subtropical regions of both hemispheres. The New Zealand species is endemic.

1. **P. novae-zealandiae** *T. Kirk in Trans. N.Z. Inst.* ix (1877) 547, t. 29.—Very slender. Leaves distant, $\frac{3}{4}$–2 in. long. Peduncle about $\frac{1}{4}$ in. long, erect. Sporocarp $\frac{1}{6}$ in. diam., globose, densely hairy, 2-celled and 2-valved. Macrosporangia 10–12 to each cell, subglobose, not constricted at the middle.—*Thoms. N.Z. Ferns* (1882) 100; *Bak. Fern Allies* (1887) 148; *Cheesem. Man. N.Z. Fl.* (1906) 1030.

North Island: Auckland—Lake Whangape, *T. Kirk.* South Island: Canterbury—Lake Lyndon, Lake Pearson, and other lakes in the Waimakariri district, *T. Kirk! Enys! Berggren, T. F. C.*

Probably not an uncommon plant, but very easily overlooked.

Family III. **SALVINIACEAE.**

Fugacious annuals, of small size, floating in quiet waters. Stems simple or branched. Leaves small, often minute, apparently distichous, sessile or shortly petiolate, simple or lobed. Sporocarps or conceptacles on the under-surface of the stem, either clustered on the divisions of an altered submerged leaf, or in pairs in the axils of the leaves, globose or ovoid, membranous, indehiscent, of two kinds, both borne on the same plant; one kind containing a single or many macrosporangia, the other enclosing numerous microsporangia. Macrosporangia containing a single macrospore; microsporangia with numerous microspores.

Genera 2; species about 18, mainly tropical or subtropical. In germination the macrospore produces a rather large prothallium, which remains attached to it, and which bears one or more archegonia. The microspores each develop a rudimentary prothallium bearing a single antheridium containing spermatozoids, fertilization taking place in the same way as in ferns. In the genus *Salvinia*, which is not found in New Zealand, the antheridia are formed while the microspores are contained within the microsporangium; but in *Azolla* the microspores escape in groups called massulae, each with its proper membrane, and the antheridia are developed within the massulae.

1. **AZOLLA** Linn.

Floating water-plants. Stems copiously pinnately branched, emitting on the under-side numerous rootlets. Leaves densely imbricating, very minute, sessile, deeply and unequally 2-lobed. Sporocarps or conceptacles in pairs in the axils of the leaves on the under-surface of the stem, of two kinds: one kind larger, globose, enclosing numerous microsporangia, each of which contains numerous microspores arranged in separate groups or massulae furnished with a membranous envelope; the other smaller, ovoid, containing a single macrosporangium within which is a solitary macrospore. Macrospores each crowned with few or many swimming-floats; massulae of the microspores armed with simple or hooked bristles.

A small genus of 4 or 5 species, found in most tropical or warm temperate regions.

1. **A. rubra** *R. B. Prodr.* (1810) 167.—Floating, red or reddish-green, often gregarious and covering large sheets of water; the separate plants ½–1 in. long, orbicular or ovate or somewhat deltoid, copiously bipinnate. Leaves densely imbricating, about $\frac{1}{20}$ in. long, 2-lobed, the lobes ovate, obtuse. Larger sporocarps globose, about $\frac{1}{20}$ in. diam.; the massulae of the microspores armed with copious hooked bristles. Smaller sporocarps hardly more than half the size, oblong; the solitary macrospore crowned with 3 swimming-floats.—*Hook. f. Fl. Nov. Zel.* ii (1855) 56; *Handb. N.Z. Fl.* (1864) 392; *Benth. Fl. Austral.* vii (1878) 680; *Bak. Fern Allies* (1887) 137; *Cheesem. Man. N.Z. Fl.* (1906) 1031.

North and South Islands, Stewart Island: Abundant in still waters throughout.

Also found in Australia and Tasmania, and very closely allied to the South American *A. filiculoides* Lam., of which some authors consider it to be a variety.

Family IV. **LYCOPODIACEAE.**

Perennials, from a few inches to a few feet high. Stems erect or pendulous, or prostrate or creeping, simple or more usually dichotomously branched, often hard and wiry, usually leafy throughout. Leaves small, simple, entire or serrulate, more or less decurrent at the base, indistinctly

1-nerved, either spreading all round the axis and of the same shape and size, or dimorphous with the larger ones distichously spreading. Sporangia all of one kind, coriaceous, 1-celled in the typical genera, 2–3–4-celled in *Tmesipteris* and *Psilotum*, borne singly on the upper base of fertile leaves or sporophylls. Sporophylls either similar to the foliage-leaves and placed all down the stem, or more or less reduced in size and bract-like and aggregated into terminal spikes or cones, in *Tmesipteris* and *Psilotum* deeply bifid with the sporangia attached below the fork. Spores all of one kind, numerous, tetrahedral, marked with 3 radiating lines at the tip.

A family containing 4 genera and over 125 species, quite cosmopolitan in its distribution, and without any important economical properties or uses. The germination of the spores has so far been observed in only a comparatively small proportion of the species. The prothallium is monoecious, as in ferns, producing both archegonia and antheridia, but the species which have been examined exhibit great diversities in the shape and mode of growth of the prothallium and in its duration; and considerable variety also exists in the development of the embryonic plant. For particulars reference must be made to special text-books or memoirs. As a matter of convenience, I have retained *Tmesipteris* and *Psilotum* in the order, but the structure of the sporangia and form of the sporophylls are so distinct that there can be little doubt that Pritzel and other authors are right in placing them in a distinct family.

A. Lycopodiineae. *Fertile leaves or sporophylls (bracts) simple, not forked. Sporangia reniform, compressed, 1-celled, dehiscing by a longitudinal slit.*

Minute. Stem reduced to a small tuber crowned by subulate leaves. Sporangia forming a cone-like spike at the top of a naked peduncle .. .. 1. PHYLLOGLOSSUM.

Larger. Stem conspicuous, branched, leafy throughout. Sporangia collected into terminal or lateral spikes, rarely scattered along the branches. .. .. 2. LYCOPODIUM.

B. Psilotineae. *Fertile leaves or sporophylls forked. Sporangia (synangia) 2–3–4-celled and valved, attached to the sporophylls below the fork.*

Stems simple or rarely forked. Leaves conspicuous, vertical. Synangia boat-shaped, 2-celled .. .. 3. TMESIPTERIS.

Stems many times dichotomous. Leaves minute, scale-like. Synangia subglobose, usually 3-celled .. .. .. 4. PSILOTUM.

The life-history of the *Lycopodiaceae* of New Zealand has been fully and ably investigated by the Rev. J. E. Holloway in a series of memoirs contributed to the *Transactions of the New Zealand Institute*, as follows: "Studies in the New Zealand Species of *Lycopodium*," Part I, vol. xlviii, 1916; Part II, "Methods of Vegetative Reproduction," vol. xlix, 1917; Part III, "The Plasticity of the Species," vol. li, 1919; "The Prothallus and Young Plant of Tmesipteris," vol. l, 1918; Part IV, "The Structure of the Prothallus in Five Species," vol. lii, 1920; and "Further Studies on the Prothallus of Tmesipteris," vol. liii, 1921. No student of the family can afford to neglect these important contributions. I have also to tender my acknowledgments to Mr. Holloway for valuable assistance rendered in the preparation of this work.

1. **PHYLLOGLOSSUM** Kunze.

A small stemless plant, consisting of an oblong tuber (protocorm) which is annually reproduced, and which bears at its apex a tuft of terete subulate leaves. Roots few, simple, springing from above the tuber directly below the leaves. Peduncle arising from the apex of the tuber and surrounded at its base by the leaves, short, erect, simple or very rarely forked, ending in a short fertile spike or cone. Bracts several, imbricated, broadly ovate, cuspidate, each supporting a single reniform 1-celled sporangium, which dehisces by a longitudinal slit. Spores small, numerous, with three lines radiating from the apex.

A genus of a single species, found in New Zealand, Tasmania, Victoria, and West Australia.

1. **P. Drummondii** *Kunze in Bot. Zeit.* (1843) 721.—Whole plant 1–2½ in. high, green, perfectly glabrous. Tuber small, oblong, producing another (rarely two more) during the growing season, the new tuber remaining dormant during the summer and reproducing the plant the following winter, the original tuber and its leaves shrivelling after the ripening of the sporangia. Leaves usually from 4–10, but varying in number from 1 or 2 to 15 or even 20, ⅛–¾ in. long, linear-subulate, acute, fleshy, cylindrical. Peduncle 2 or 3 times as long as the leaves, stout, erect. Spike ⅙–⅓ in. long, oblong-ovoid, terete; bracts 10–30, broad, the erect cusp overtopping the sporangium.—*Hook. Ic. Plant.* (1854) t. 908; *Hook. f. Fl. Nov. Zel.* ii (1855) 51; *Fl. Tasm.* ii (1860) 154; *Handb. N.Z. Fl.* (1864) 388; *Bak. Fern Allies* (1887) 7; *Thoms. N.Z. Ferns* (1882) 102; *Cheesem. Man. N.Z. Fl.* (1906) 1033. Lycopodium sanguisorba *Spring. Monog. Lycop.* ii (1848) 36.

North Island: Barren clay hills from the North Cape to the Thames Valley and the Middle Waikato (Lake Waikare), not uncommon. South Island: Said to have been gathered near Picton by *Helms*, and on Banks Peninsula by *Armstrong*, but I have seen no specimens.

A remarkable little plant, differing from all other Lycopods in its vegetative characters, but with the spike and sporangia of *Lycopodium*. The tuber and its leaves are so similar in appearance and mode of development to the embryonic plant of some species of *Lycopodium*, and notably to that of *L. cernuum*, with its protocorm or embryonic tubercle, and protophylls or primordial leaves, that both Bower and Treub have expressed the opinion that *Phylloglossum* should be regarded as a permanently embryonic form of Lycopod. The important discovery made by Thomas that the prothallium and development of the embryo is of the same type as that of *Lycopodium cernuum* may be regarded as a satisfactory proof of the correctness of this view; and it seems in every way probable that Thomas is correct in considering *Phylloglossum* to be the most primitive of existing *Lycopodiaceae*. For information on the subject the student should consult Professor Bower's two memoirs "On the Development and Morphology of *Phylloglossum Drummondii*" and "On the Morphology of the Spore-producing Members" (Trans. Roy. Soc. 1886, p. 665, and 1894, p. 508–10); also Treub's paper in the Annals of the Bot. Garden of Buitenzorg, vol. viii, p. 1 *et seq.*; and Professor Thomas's "Preliminary Account of the Prothallium of *Phylloglossum*" (Proc. Roy. Soc., vol. lxix, p. 285–91, reprinted in Trans. N.Z. Inst. xxxiv, 402–8). Other papers on the subject will be found in the "Annals of Botany" and the *Botanical Gazette*.

2. **LYCOPODIUM** Linn.

Stems erect or pendulous, or prostrate and creeping, copiously branched, rarely simple, often hard and wiry, usually leafy throughout. Leaves small, crowded or imbricate, 1-nerved, entire or denticulate, generally uniform in size and multifarious, but in a few species dimorphous and distichous. Sporangia 1-celled, reniform, compressed, coriaceous, dehiscing by a longitudinal slit, placed singly on the upper surface of the leaves near their base, or more generally at the upper base of imbricated bracts aggregated into terminal spikes, which are either sessile or pedunculated. Spores small, numerous, with three lines radiating from the apex.

A large genus of about 100 species, found in all parts of the world. Of the 11 species indigenous in New Zealand, 3 are widely distributed in both hemispheres, 6 extend to Australia, 2 of them reaching the Pacific islands as well, the remaining 1 or 2 are endemic.

A. Selago. *Leaves multifarious. Sporangia at the upper base of unaltered leaves at intervals all down the stem.*

Stems 3–12 in., tufted, erect, dichotomously forked. Leaves crowded, erect, subulate-lanceolate, ⅙–¼ in. long .. .. 1. *L. Selago.*

B. Lepidotis. *Leaves multifarious. Sporangia aggregated into distinct terminal spikes, at the upper base of bracts differing in shape and size from the leaves.*

* Epiphytic or rupestral, rarely terrestrial. Stems often pendulous, dichotomously forked from the base. Spikes slender, tetragonous.

Stems 6–24 in., usually erect, stout, rigid. Spikes 2–6 in., stout, curved; bracts about $\frac{1}{8}$ in., the upper decidedly longer than the sporangia .. .. 2. *L. varium.*
Stems 1–5 ft., pendulous, very slender. Spikes 1–4 in.; bracts $\frac{1}{20}$–$\frac{1}{12}$ in., the upper scarcely longer than the sporangia .. 3. *L. Billardieri.*

** Stems erect, rigid, dendroid, simple below, copiously branched above. Spikes terminal, sessile, cylindrical.

Stems 1–3 ft.; branches ascending, dense, fastigiate. Spikes $\frac{1}{2}$–1 in., erect; bracts broadly ovate, acute but not cuspidate 4. *L. densum.*
Stems $\frac{3}{4}$–2 ft.; branches spreading. Spikes $\frac{1}{4}$–$\frac{1}{2}$ in., incurved or pendulous; bracts broadly ovate with a long cuspidate point 5. *L. cernuum.*

*** Stems slender, erect or procumbent, sparingly or diffusely branched. Spikes lateral or terminal on short lateral branchlets.

Stems 4–18 in., erect, simple or dichotomously forked; branches erect. Spikes lateral, sessile, $\frac{1}{2}$–$\frac{2}{3}$ in. long .. .. .. 6. *L. laterale.*
Stems 2–9 in., procumbent or prostrate, much branched, often with the branches interlaced. Spikes terminating short lateral branchlets .. .. 7. *L. ramulosum.*

**** Main stem creeping, with erect or ascending branches. Spikes terminal, on long peduncles.

Stems 2–6 in., creeping and rooting, leafy; fertile branches or peduncles simple, strict, erect, 2–6 in. long. Spikes $\frac{1}{3}$–$\frac{1}{2}$ in. .. 8. *L. Drummondii.*
Stems 6–24 in., creeping; branches 3–14 in., erect or ascending, fastigiately branched. Spikes $\frac{3}{4}$–2 in. long, on peduncles terminating the upper branchlets.. .. .. .. 9. *L. fastigiatum.*

C. Diphasium. *Leaves distichous and dimorphous. Sporangia aggregated into distinct terminal spikes; bracts small.*

Stems 1–3 ft., creeping; branches 3–12 in., ascending or erect, flattened. Spikes 1–2 in., solitary, terminal; bracts with spreading tips .. .. 10. *L. scariosum.*
Stems 2–8 ft., scrambling or climbing; branches flabellately divided, flattened. Spikes 1–4 in., in large panicles at the ends of the branches; bracts with small appressed tips .. 11. *L. volubile.*

1. **L. Selago** *Linn. Sp. Plant.* (1753) 1565.—Stems 3–12 in. long, usually shortly decumbent and rooting at the base, erect above, several times dichotomously forked, densely leafy throughout; branches 2–9 in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. diam. including the leaves, stout, rigid, erect, cylindric, often uniform in height and forming dense level-topped tufts. Leaves crowded, ascending or rarely spreading, $\frac{1}{6}$–$\frac{1}{4}$ in. long, subulate-lanceolate, acuminate, sometimes almost pungent, quite entire or minutely denticulate, firm, dark-green and glossy, sometimes with pedicelled leafy bulbils in the axils. Sporangia solitary on the upper surface of the unaltered leaves near their base, often at intervals all down the stem, but usually most abundant in the upper part, not forming a distinct spike.—*Hook. f. Fl. Nov. Zel.* ii (1855) 52; *Fl. Tasm.* ii (1860) 155, t. 170A; *Handb. N.Z. Fl.* (1864) 389; *Benth. Fl. Austral.* vii (1878) 674; *Bak. Fern Allies* (1887) 9; *Thoms. N.Z. Ferns* (1882) 108; *Cheesem. Man. N.Z. Fl.* (1906) 1035.

North Island: Mountainous districts from Mount Tauhara (near Lake Taupo) southwards to the Tararua Range, apparently local. South Island, Stewart Island: Abundant in mountain districts, usually between 1500 and 5000 ft., but descends almost to sea-level in Stewart Island.

An abundant plant on moors and heaths in cool or damp mountainous localities throughout the world.

2. **L. varium** *R. Br. Prodr.* (1810) 165.—Stems tufted, much branched from the base, ½–2 ft. long, stout, rigid, erect or more rarely pendulous, sparingly or much dichotomously branched, leafy throughout; branches stout, often curved. Leaves crowded all round the branches, ascending or spreading, the lower ones the longest, ⅓–⅔ in. long, lanceolate, obtuse or subacute, coriaceous, dark-green and glossy, midrib usually obscure; upper leaves smaller and more appressed. Spikes terminal, usually numerous, simple or branched, curved or drooping, tetragonous, 2–6 in. long, ⅛–⅙ in. diam. Bracts densely imbricating, about ⅛ in. long, broadly ovate, acute or obtuse, keeled; the lower ones rather longer and more foliaceous, gradually passing into the upper leaves, the upper decidedly longer than the reniform sporangia.—*Hook. and Grev. Ic. Fil.* (1829) t. 112; *Hook. f. Fl. Antarct.* i (1844) 115; *Fl. Nov. Zel.* ii (1855) 52; *Fl. Tasm.* ii (1860) 155, t. 170B; *Handb. N.Z. Fl.* (1864) 389; *Benth. Fl. Austral.* vii (1878) 674; *Bak. Fern Allies* (1887) 21; *Thoms. N.Z. Ferns* (1882) 104; *Cheesem. Man. N.Z. Fl.* (1906) 1035.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands, Antipodes Island, Macquarie Island: Mountainous districts from the Great Barrier Island and Cape Colville southwards, not uncommon. Sea-level to 4500 ft.

Also in Australia and Tasmania. Possibly only an extreme form of *L. Billardieri*, into which it passes by imperceptible gradations, but in its usual state distinguished without much difficulty by the stout rigid habit, stouter curved spikes, and larger bracts. It is usually terrestrial or rupestral, rarely epiphytic. In Stewart Island it occasionally forms large patches sometimes 10 or 12 ft. across.

3. **L. Billardieri** *Spring. Monog. Lycop.* i (1841) 56.—Stems tufted, pendulous from the branches of trees or from rocks, more rarely growing on peaty soil or on humus, 1–5 ft. long, excessively dichotomously branched from the base upwards, slender, cylindric, dark-green, leafy throughout; upper branches almost flaccid. Lower leaves laxly placed, spreading or ascending from an erect decurrent base, ½–¾ in. long, linear or linear-ligulate, obtuse or acute, coriaceous, usually with a distinct midrib; upper shorter and more closely placed, more erect, often appressed and imbricating, ¼ in. long, linear-subulate, acute, more or less keeled. Spikes terminating the branches, very numerous, slender, dichotomously forked, tetragonous, 1–4 in. long, $\frac{1}{12}$–$\frac{1}{10}$ in. diam. Bracts densely imbricating, short, $\frac{1}{25}$–$\frac{1}{15}$ in. long, broadly ovate, acute or apiculate, keeled, the upper ones sometimes no longer than the reniform sporangia.—*Hook. f. Fl. Nov. Zel.* ii (1855) 53; *Handb. N.Z. Fl.* (1864) 389; *Bak. Fern Allies* (1887) 20; *Thoms. N.Z. Ferns* (1882) 104; *Cheesem. Man. N.Z. Fl.* (1906) 1036. L. varium *var.* Billardieri *T. Kirk in Trans. N.Z. Inst.* xvi (1884) 377. L. flagellaria *A. Rich. Fl. Nouv. Zel.* (1832) 60 (*not of Bory*); *A. Cunn. Precur.* (1836) n. 155; *Raoul Choix* (1846) 37. L. Phlegmaria *A. Cunn. Precur.* (1836) n. 157 (*not of Linn.*).

Var. **gracile** *T. Kirk in Trans. N.Z. Inst.* xvi (1884) 377.—Stems tufted, usually pendulous, 6–12 in. long, slender, pale-green, flaccid. Leaves spreading, about ½ in. long, narrow-linear, acute or obtuse. Spikes lax, slender, often ill-defined, 3–6 in. long, simple or forked. Bracts about ¼ in. long, linear, spreading or ascending, 3 or 4 times as long as the sporangia.—(?) L. novae-zealandicum *Col. in Trans. N.Z. Inst.* xix (1887) 275.

Kermadec Islands, North and South Islands, Stewart Island: The typical form abundant in woods throughout. Var. *gracile:* Mount Egmont, *T. F. C.;* Wairarapa Valley, *J. S. Sandager!* Maitai Valley, *Dr. Boor* and *T. Kirk;* Westport,

Dr. Gaze! Otira Gorge, *T. F. C.* Very abundant in Westland, especially on the trunks of *Dicksonia squarrosa, Holloway!* Sea-level to 2000 ft.

A very variable plant, which cannot be separated by any positive characters from *L. varium*. Var. *gracile* is more distinct, and might almost be distinguished as a separate species.

4. **L. densum** *Labill. Pl. Nov. Holl.* ii (1806) 104, t. 251.—Rhizome long, stout, subterranean, frequently 4–6 ft. in length. Stems rigidly erect, woody, dendroid, 1–4 ft. high, or even more when drawn up by surrounding vegetation, simple below, much and densely fastigiately branched above; branches repeatedly divided; branchlets slender, ascending, $\frac{1}{16}$–$\frac{1}{8}$ in. diam. Leaves inserted all round the stem and branches, distant towards the base of the stem, much closer together above. There are three distinct types of foliage, usually confined to separate branches, that most generally seen being erect, densely imbricating and closely appressed to the branch, $\frac{1}{20}$–$\frac{1}{12}$ in. long, subulate-lanceolate and shortly aristate. In the other types the foliage is larger, and erecto-patent or squarrose. Spikes solitary and terminal on the branchlets, very numerous, erect, $\frac{1}{2}$–1 in. long, about $\frac{1}{8}$ in. diam., cylindric, obtuse. Bracts close-set, broadly ovate, acute but not cuspidate, spreading when mature; margins scarious, jagged. Spores echinate—*A. Cunn. Precur.* (1836) n. 153; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 53; *Handb. N.Z. Fl.* (1864) 389; *Benth. Fl. Austral.* vii (1878) 676; *Bak. Fern Allies* (1887) 24; *Cheesem. Man. N.Z. Fl.* (1906) 1036.

North Island: Abundant from the North Cape to Poverty Bay and Kawhia, usually in light scrub on clay soils. South Island: Marlborough, *Buchanan.* Nelson—Lower Takaka, Denniston (near Westport), *J. E. Holloway!* Chatham Islands: *Dieffenbach.* Sea-level to 3000 ft.

Also in Norfolk Island, Australia and Tasmania, and New Caledonia. I had supposed that the differences in foliage represented sterile or juvenile branches, but Mr. Holloway informs me that such differences do not depend upon whether the plant is young or old, sterile or fertile.

5. **L. cernuum** *Linn. Sp. Plant.* (1753) 1566.—Stems stout, creeping by successive loops which root at the nodes, 1–10 ft. long, leafy throughout; primary branches rigidly erect, 9–18 in. long or more, much branched in the upper portion, usually simple below; lower branchlets copiously divided, short, spreading or ascending, pendulous towards the tips. Leaves inserted all round the stems and branches, crowded, squarrose or incurved towards the tips, $\frac{1}{10}$–$\frac{1}{8}$ in. long, narrow linear-subulate, decurrent at the base, pale soft-green, keeled by the prominent midrib beneath. Spikes numerous, solitary and sessile on the incurved or pendulous tips of the branchlets, $\frac{1}{4}$–$\frac{1}{2}$ in. long, oblong, obtuse, cylindric. Bracts imbricating all round, broadly ovate, narrowed into a long cuspidate point; margins denticulate.—*A. Cunn. Precur.* (1836) n. 154; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 54; *Handb. N.Z. Fl.* (1864) 390; *Benth. Fl. Austral.* vii (1878) 676; *Bak. Fern Allies* (1887) 23; *Thoms. N.Z. Ferns* (1882) 105; *Cheesem. Man. N.Z. Fl.* (1906) 1037. (?) L. polycephalum *Col. in Trans. N.Z. Inst.* xvii (1885) 401.

Kermadec Islands: Sunday Island, in the large crater-basin, not common, *T. F. C., W. R. B. Oliver!* North Island: From the North Cape to the East Cape and Taupo, abundant to the north of the Thames and Waikato Rivers, and in great profusion in heated soil in the thermal-springs district, from Rotorua to Taupo. Sea-level to 2500 ft. South Island: West Wanganui, *B. C. Aston!*

A common tropical plant all round the world. Frequently luxuriating in the neighbourhood of hot springs.

6. **L. laterale** *R. Br. Prodr.* (1810) 165.—Rhizome long, stout, white, creeping, much branched. Stems numerous, erect or decumbent at the base, 4–24 in. high, stout or slender, simple or sparingly branched, the branches erect, cylindric, pale-green, sometimes tinged with reddish-brown, leafy from the base. Leaves close-set, spreading all round or the upper ascending, $\frac{1}{8}$–$\frac{1}{4}$ in. long, subulate-lanceolate, acuminate, decurrent at the base, firm but hardly coriaceous; midrib evident; margins revolute. Spikes 2–8 to a branch, lateral or sometimes terminal on very short leafy shoots, sessile, simple, erect, $\frac{1}{3}$–$\frac{2}{3}$ in. long, oblong, obtuse, often brown or reddish-brown. Bracts imbricated, spreading at maturity, broadly ovate, suddenly narrowed into a rather long acuminate point; margins jagged.—*A. Cunn. Precur.* (1836) n. 156; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 53; *Handb. N.Z. Fl.* (1864) 389; *Benth. Fl. Austral.* vii (1878) 675; *Bak. Fern Allies* (1887) 28; *Thoms. N.Z. Ferns* (1882) 106; *Cheesem. Man. N.Z. Fl.* (1906) 1037. L. consimile *Col. in Trans. N.Z. Inst.* xvi (1884) 348.

North and South Islands, Chatham Islands: Abundant in swampy or peaty ground throughout. Sea-level to 2500 ft.

Also found in Australia, from Queensland to Victoria, and in New Caledonia.

7. **L. ramulosum** *T. Kirk in Trans. N.Z. Inst.* xi (1879) 456, t. 19B.—Rhizome creeping, branched. Stems 2–9 in. long, prostrate or procumbent, usually much branched and densely intermatted, but sometimes lax and open; branches ascending at the tips, pale-green, often tinged with reddish, leafy throughout. Leaves rather close, spreading or ascending, about $\frac{1}{6}$ in. long, subulate-lanceolate, mucronate, decurrent at the base, keeled, firm but scarcely coriaceous, quite entire. Spikes solitary and sessile at the end of short leafy branchlets, sometimes terminating the main branches; occasionally the branches are so much reduced that the spike becomes lateral as in *L. laterale*, $\frac{1}{4}$–$\frac{1}{2}$ in. long, oblong, obtuse, brown or reddish-brown. Bracts imbricated, ascending, broadly ovate, abruptly acuminate or cuspidate, coriaceous; margins entire or slightly toothed.—*Bak. Fern Allies* (1887) 25; *Thoms. N.Z. Ferns* (1882) 105; *Cheesem. Man. N.Z. Fl.* (1906) 1038; *Ill. N.Z. Fl.* ii (1914) t. 250.

South Island: Nelson—Vicinity of Westport, *W. Townson!* Westland—Very abundant in sphagnum bogs, *J. E. Holloway!* near Hokitika, *W. Tipler;* Kumara, *J. W. Brame!* Okarito, *A. Hamilton!* Stewart Island: Paterson's Inlet, *T. Kirk!* plentiful, *Cockayne!* Usually in open peaty land or in swampy woods. Sea-level to 3000 ft.

More closely allied to the Australian *L. diffusum* than to any other species, principally differing, as Mr. Baker has remarked, in its entirely terminal spikes, whereas in *L. diffusum* they are frequently lateral. In its usual state it is easily separated from *L. laterale* by its densely branched habit of growth and by the procumbent or prostrate stems.

8. **L. Drummondii** *Spring. Monog. Lycop.* ii (1848) 35.—Main stem creeping over the surface of the ground and producing copious roots, more or less branched, 3–6 in. long or even more, putting up here and there distant rigidly erect fertile branches 4–8 in. high. Leaves of the main stem uniform, crowded, dark-green, ascending, imbricate, linear-lanceolate, acuminate, quite entire, $\frac{1}{8}$ in. long; midrib faint; texture firm. Leaves of the fertile branches not so closely placed, erecto-patent. Spikes variable in length, 1–3 in. or even more. Bracts deltoid with a long cuspidate point, erecto-patent or the lower spreading, greenish-yellow.—*Bak. Fern Allies* (1887) 25; *Cheesem. Man. N.Z. Fl.* (1906) 1038. L. caroli-

nianum *Hook. f. Fl. Nov. Zel.* ii (1855) 54; *Handb. N.Z. Fl.* (1864) 390; *Benth. Fl. Austral.* vii (1878) 675; *Thoms. N.Z. Ferns* (1882) 106 (*not of Linn.*). L. serpentinum *Kunze in Pl. Preiss.* ii 108.

North Island: Auckland—Peaty swamp near the outlet of Lake Tongonge, near Kaitaia, North Cape district, *R. H. Matthews! H. B. Matthews! H. Carse!* The only locality known for the species in New Zealand, and no doubt the one in which it was originally discovered by Mr. Colenso in 1839. It is also a native of Australia, and is very closely allied to the tropical *L. carolinianum* Linn., principally differing in the stem-leaves being all similar, and not dimorphic.

9. **L. fastigiatum** *R. Br. Prodr.* (1810) 165.—Main stem or rhizome stout, creeping, subterranean, 6–24 in. long or more; primary branches rather distant, 3–14 in. long, stout, erect, rigid, often naked below, copiously fastigiately branched above; branchlets crowded. Leaves imbricated all round the branches, crowded, spreading and then incurved at the tips, $\frac{1}{8}$–$\frac{1}{6}$ in. long, linear or linear-lanceolate, acute or shortly mucronate, not hair-pointed, entire, firm, midrib indistinct. Spikes peduncled, often two together, terminating the upper branchlets or several in a central panicle, $\frac{3}{4}$–2 in. long, rarely more, about $\frac{1}{6}$ in. diam., erect, cylindric. Bracts closely imbricate, broadly ovate at the base, narrowed upwards into a long spreading or recurved cuspidate point.—*Bak. Fern Allies* (1887) 27; *Cheesem. Man. N.Z. Fl.* (1906) 1039. L. clavatum *var.* magellanicum *Hook. f. Fl. Antarct.* i (1844) 113; *Fl. Nov. Zel.* ii (1855) 54; *Handb. N.Z. Fl.* (1864) 390; *Thoms. N.Z. Ferns* (1882) 106 (*but not of Swartz*). L. clavatum *var.* fastigiatum *Benth. Fl. Austral.* vii (1878) 675. L. curvifolium *and* L. scopulosum *Col. in Trans. N.Z. Inst.* xx (1888) 234 *and* 235. L. decurrens *Col. l.c.* xxviii (1896) 617.

North Island: Hilly and mountainous localities from Cape Colville to Cook Strait, but local to the north of the East Cape. South Island, Chatham Islands, Stewart Island, Auckland and Campbell Islands, Antipodes Island: Abundant throughout. Sea-level to 5000 ft.

Also in Victoria and Tasmania, and very close to some forms of the widely distributed *L. clavatum* Linn., from which it is chiefly distinguished by the absence of hair-points to the leaves and their entire margins.

10. **L. scariosum** *Forst. f. Prodr.* (1786) n. 484.—Main stems prostrate or creeping, stout, branched, 1–3 ft. long; branches numerous, rigid, erect or ascending, copiously divided, 3–12 in. long; branchlets flattened, $\frac{1}{8}$–$\frac{1}{6}$ in. broad including the leaves. Leaves of the main stem inserted all round, appressed, lanceolate or subulate-lanceolate, with acute scarious tips; of the branchlets dimorphous, the larger distichously spreading and flattened, about $\frac{1}{8}$ in. long, ascending, much decurrent at the base, lanceolate or ovate-lanceolate, acute or acuminate, falcate, coriaceous, dark-green or yellow-green; smaller leaves on one side of the branchlets subulate-lanceolate, appressed, usually with scarious tips. Spikes solitary at the end of the branchlets, 1–2 in. long, about $\frac{1}{6}$ in. diam., on long or short peduncles clothed with appressed imbricate leaves. Bracts closely imbricated, broadly ovate at the base, narrowed upwards into a long spreading or recurved scarious tip; margins often toothed.—*Hook. Ic. Plant.* (1854) t. 966; *Raoul Choix* (1846) 37; *Hook. f. Fl. Antarct.* i (1844) 112; *Fl. Nov. Zel.* ii (1855) 55; *Handb. N.Z. Fl.* (1864) 390; *Benth. Fl. Austral.* vii (1878) 676; *Bak. Fern Allies* (1887) 29; *Thoms. N.Z. Ferns* (1882) 107; *Cheesem. Man. N.Z. Fl.* (1906) 1039. L. Lessonianum *A. Rich. Fl. Nouv. Zel.* (1832) 59; *A. Cunn. Precur.* (1836) n. 152. L. distans *Col. in Trans. N.Z. Inst.* xx (1888) 236.

North and South Islands, Chatham Islands, Stewart Island, Auckland Islands: From the Great Barrier Island and the Manukau Harbour southwards, but often local. Sea-level to 5000 ft.

A handsome and distinct species, a slightly different form of which is found in Victoria and Tasmania. It is also very closely allied to the South American *L. Jussiaei* Desv.

11. **L. volubile** *Forst. f. Prodr.* (1786) n. 482.—Stems 2–12 ft. long or more, branched, scrambling over bushes or rocks, slender, wiry, flexuose, with distant minute linear-subulate appressed leaves. Branches numerous, leafy, compressed, pinnately or flabellately decompound; branchlets forked, the ultimate ones $\frac{1}{2}$–3 in. long, $\frac{1}{6}$–$\frac{1}{4}$ in. broad including the leaves. Leaves dimorphous, the larger distichously spreading, $\frac{1}{8}$–$\frac{1}{6}$ in. long, with a broad adnate decurrent base, ascending, lanceolate, strongly falcate, acuminate, midrib evident, oblique, texture firm; smaller leaves much reduced in size, linear, appressed. Spikes very numerous, 1–4 in. long, $\frac{1}{12}$ in. broad, cylindrical, pendulous, arranged in large terminal much-branched panicles 6–24 in. long. Bracts imbricating, small, not much longer than the sporangia, broadly ovate or almost orbicular, suddenly narrowed into an erect subulate point.—*A. Cunn. Precur.* (1836) n. 158; *Raoul Choix* (1846) 37; *Hook. and Grev. Ic. Fil.* (1829) t. 170; *Hook. f. Fl. Nov. Zel.* ii (1855) 55; *Handb. N.Z. Fl.* (1864) 391; *Benth. Fl. Austral.* vii (1878) 677; *Bak. Fern Allies* (1887) 29; *Thoms. N.Z. Ferns* (1882) 107; *Cheesem. Man. N.Z. Fl.* (1906) 1040. L. D'Urvillei *A. Rich. Fl. Nouv. Zel.* (1832) 60 (*not of Bory*).

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant throughout, usually forming entangled masses among low scrub. Sea-level to 3000 ft. *Waewaekoukou.*

By far the most beautiful species of the genus. It extends to Polynesia, New Caledonia, North Australia, the mountains of New Guinea, Java, Borneo, and the Malay Peninsula.

3. **TMESIPTERIS** Bernh.

Rhizome long, creeping, much branched; true roots wanting. Stems simple or rarely forked, pendulous or ascending, leafy. Leaves vertically placed, of two kinds: the foliage-leaves sessile and decurrent, simple and entire; the fertile leaves or sporophylls mixed with the foliage-leaves and about the same size, shortly petiolate, bipartite. Sporangia (or synangia) attached to the petiole of the fertile leaf just below the lobes, boat-shaped or spindle-shaped, coriaceous, pointed at both ends, slightly constricted about the middle, 2-celled with the septum across the narrow diameter, dehiscing longitudinally; rarely the sporangia are 3-celled or 1-celled. Spores minute, oblong.

A genus consisting of one highly variable species, found in New Zealand, Australia and Tasmania, and some of the Pacific islands. By some authors it is split up into 3 or 4, distinguished mainly by the shape of the apex of the leaf (which I find to be variable even in the same individual) and by certain histological details, the constancy of which has yet to be established.

1. **T. tannensis** *Bernh. in Schrad. Journ. Bot.* ii (1800) 131, t. 2.—Stems 4–18 in. long or more, simple or rarely once or twice forked, usually pendulous, slender, naked towards the base. Foliage-leaves rather closely placed, $\frac{1}{3}$–1 in. long, obliquely oblong or oblong-lanceolate, sessile and strongly decurrent at the base, obtuse or truncate or acute at the tip, the

midrib usually produced into a mucro of variable length, coriaceous, dark dull-green. Fertile leaves rather shorter than the foliage-leaves and replacing them at intervals down the stem, on short petioles sometimes $\frac{1}{4}$ in. long, deeply 2-partite, the divisions usually similar to the foliage-leaves but smaller. Synangia sessile or very shortly stalked, $\frac{1}{6}$–$\frac{1}{4}$ in. long, parallel to the petiole, brown, coriaceous.—*Benth. Fl. Austral.* vii (1878) 680; *Bak. Fern Allies* (1887) 30; *Cheesem. Man. N.Z. Fl.* (1906) 1041. T. Forsteri *Endl. Prodr. Fl. Norfolk.* (1833) 6; *A. Cunn. Precur.* (1836) n. 151; *Raoul Choix* (1846) 37; *Hook. f. Fl. Nov. Zel.* ii (1855) 51; *Handb. N.Z. Fl.* (1864) 391; *Thoms. N.Z. Ferns* (1882) 108. T. truncata *Desv. in Ann. Soc. Linn. Par.* vi, 192; *Hook. Gen. Fil.* (1842) t. 86.

KERMADEC ISLANDS, NORTH AND SOUTH ISLANDS, CHATHAM ISLANDS, STEWART ISLAND, AUCKLAND ISLANDS: Common in forests throughout, particularly on the western sides of the islands, usually epiphytic on the stems of tree-ferns, more rarely on rocks. Sea-level to 3000 ft.

For a discussion on the morphology and systematic position of this plant see Professor Bower's memoir "On the Morphology of the Spore-producing Members" (Trans. Roy. Soc. 1894, p. 541–48) and the more recently published paper by Professor Thomas entitled "The Affinity of *Tmesipteris* with the *Sphenophyllales*" (Proc. Roy. Soc. vol. lxix, p. 343–50). Reference should also be made to Mr. Holloway's paper on "The Prothallus and Young Plant of *Tmesipteris*" (Trans. N.Z. Inst. vol. 1 (1918) 1.)

4. **PSILOTUM** Swartz.

Rhizome short, creeping, branched; true roots wanting. Stem erect or pendulous, simple below, repeatedly dichotomously branched above; branches angled or flat. Leaves very minute, scale-like, laxly placed, trifarious or distichous. Sporangia (or synangia), coriaceous, almost globular, usually 3-lobed and 3-celled, rarely 2- or 4-celled, in the axil or attached below the fork of a minute bifid scale-like fertile leaf or sporophyll, which is either sessile or raised on a short petiole. Spores minute, oblong, curved.

A small genus of two species, widely distributed in the tropical and subtropical regions of both hemispheres. The New Zealand species has the range of the genus.

1. **P. triquetrum** *Swartz Syn. Fil.* (1806) 117.—Stems 4–18 in. long, erect or pendulous when growing on trees, stout or slender, simple below, many times dichotomously branched in the upper part; branchlets triquetrous, the ultimate ones $\frac{1}{35}$–$\frac{1}{20}$ in. diam. Leaves placed on the angles of the stems and branches, distant, minute, scale-like, ovate-subulate, $\frac{1}{12}$–$\frac{1}{8}$ in. long. Fertile leaves bifid, rather smaller than the foliage-leaves, sessile or shortly petiolate. Synangia $\frac{1}{10}$–$\frac{1}{15}$ in. diam., globose or broader than long.—*Hook. Gen. Fil.* (1843) t. 87; *Fil. Exot.* (1857–59) t. 63; *Hook. f. Fl. Nov. Zel.* ii (1855) 56; *Handb. N.Z. Fl.* (1864) 391; *Benth. Fl. Austral.* vii (1878) 681; *Bak. Fern Allies* (1887) 30; *Thoms. N.Z. Ferns* (1882) 108; *Cheesem. Man. N.Z. Fl.* (1906) 1041. P. heterocarpum *Col. in Trans. N.Z. Inst.* xx (1888) 237.

KERMADEC ISLANDS: Not uncommon, *T. F. C.*, *W. R. B. Oliver!* NORTH ISLAND: Rangaunu Harbour, *R. H. Matthews!* Rangitoto Island, *Colenso!* and many others; Auckland Isthmus, very rare, *T. F. C.;* Motuhora Island (Bay of Plenty), *Joliffe;* near Maketu, *T. Kirk;* soil heated by hot springs at Orakeikorako, *T. Kirk!* Wairakei, *C. J. Norton!* and Tokaanu, *T. F. C.;* Karangahake Cliffs, Taupo, *H. Hill!* Sea-level to 1800 ft.

In all tropical and subtropical regions as far north as Japan and Florida.

Family V. **ISOETACEAE.**

Aquatic or amphibious perennials, often entirely submerged, rarely terrestrial. Stem (corm) short and tuberous, of firm texture, 2–3-lobed; roots numerous, rather fleshy, dichotomously forked, springing from the furrows of the stem. Leaves many, forming a dense tuft at the top of the stem, linear or filiform, flat in front, rounded at the back, dilated and sheathing at the base, always furnished with 4 longitudinal air-channels divided by transverse partitions, and with a single central vascular bundle; stomata present, or absent in those species which are permanently submerged. Sporangia large, membranous, placed in a hollow (fovea) of the dilated base of the leaf and sometimes partly concealed by the membranous margin (velum or indusium) of the fovea, 1-celled, but often imperfectly divided by rods or plates of tissue (trabeculae), those of the outer leaves containing macrospores, those of the inner leaves microspores. Immediately above the fovea is a flattened membranous plate called the ligule. Macrospores large, globose, usually chalky-white, with three ribs radiating from the apex. Microspores very minute, trigonous.

A very isolated family, consisting of the single genus *Isoetes*, allied on the one hand to the Lycopods and on the other to ferns. In germination a male prothallium with a single antheridium containing spermatozoids is developed within the microspore, the spermatozoids being set free by the bursting of the coats of the microspores. The macrospores in a similar manner each produce a female prothallium bearing 2 or 3 archegonia, which are ultimately exposed by the splitting of the macrospore along the three ridges. Fertilization then takes place in the same way as in ferns.

1. **ISOETES** Linn.

Characters of the order.

Widely distributed in most temperate and tropical regions. Over 60 species are admitted in the most recent enumeration, but many of them are very imperfectly known. The two found in New Zealand are endemic.

Macrospores tubercled .. .. 1. *I. Kirkii.*
Macrospores smooth .. .. 2. *I. alpinus.*

1. **I. Kirkii** *A. Braun in Berl. Monatber., July*, 1869.—Permanently submerged. Stem short, tuberous, deeply 3-lobed; roots numerous. Leaves 10–30, very slender, 3–12 in. long, about $\frac{1}{20}$ in. diam., tapering to a fine point, pale-green, diaphanous, usually with a few stomata, but with no accessory bast-bundles. Sporangia rather small, broadly oblong or almost globose, about $\frac{1}{8}$ in. long; indusium complete. Macrospores rather small, chalky-white, beset all over with small unequal tubercles. Microspores very minute, trigonous, most minutely punctate.—*T. Kirk in Trans. N.Z. Inst.* ii (1870) 107, t. 7; *Bak. Fern Allies* (1887) 127; *Thoms. N.Z. Ferns* (1882) 109; *Cheesem. Man. N.Z. Fl.* (1906) 1043.

North Island: Wairua River, *A. Thompson!* lakes in the Middle Waikato basin, abundant, *T. Kirk! T. F. C.;* Lake Rotokakahi, *T. Kirk!* Lake Taupo, *C. J. Norton!* South Island: Small lakes near Lake Tekapo, *T. F. C.* Sea-level to 2500 ft.

Best distinguished from the following species by its smaller size and more slender habit, fewer leaves, and particularly by the conspicuously tubercled macrospores.

2. **I. alpinus** *T. Kirk in Trans. N.Z. Inst.* vii (1875) 377, t. 25.—Permanently submerged; much larger and stouter than *I. Kirkii*. Stem stout, deeply 3-lobed. Leaves very numerous, 30–70, 6–18 in. long or even

more, $\frac{1}{15}$–$\frac{1}{10}$ in. broad at the middle, much dilated at the base, gradually tapering to the apex, dark-green, diaphanous, usually with a few stomata, but with no accessory bast-bundles. Sporangia oblong, $\frac{1}{6}$–$\frac{1}{5}$ in. long; indusium complete. Macrospores greyish-white, smooth or very indistinctly tubercled.—*Bak. Fern Allies* (1887) 127; *Thoms. N.Z. Ferns* (1882) 109; *Cheesem. Man. N.Z. Fl.* (1906) 1043. (?) I. multiangularis *Col. in Trans. N.Z. Inst.* xxii (1890) 449.

North Island: Lake Taupo, *C. J. Norton.* South Island: Not uncommon in lakes in mountain districts, from Nelson to the south of Otago. 1200–3000 ft.

Family VI. **PINACEAE.**

Resinous trees or shrubs, mostly evergreen, and always so in the New Zealand species. Leaves opposite or whorled or alternate, solitary or fascicled within membranous sheaths, usually narrow-linear or scale-like, rarely broad and flat (as in *Agathis*). Flowers mostly monoecious; perianth wanting in both sexes. Male flowers a cone or catkin of stamens placed on a central axis, each stamen in the axil of a scale. Anther-cells 2 or more, variously dehiscent. Female flowers consisting of ovules borne singly or several together on the surface of a scale which is usually placed in the axil of a bract. Fruit a cone with few or many woody or fleshy scales, sometimes berry-like. Seeds with or without a wing. Cotyledons two or many.

A large and important family, almost world-wide in its distribution, but most abundant in the temperate part of the Northern Hemisphere; rare in the tropics, except on high mountains; fairly well represented in the South Temperate Zone. Genera 31; species about 280. Many of the species yield valuable timber. Pines, firs, larches, cedars, cypresses in the Northern Hemisphere; the kauri, *Araucaria*, *Libocedrus*, &c., in the Southern, are well-known timber-trees of great economic and commercial value. The resinous products of the family are also of considerable importance. The most valuable are tar, turpentine, pitch, and kauri-gum. Of the two genera found in New Zealand, *Agathis* extends to Polynesia, Australia, and Malaya; while *Libocedrus* stretches as far north as Japan and California.

Leaves large, flat, oblong. Cones large, 2–3 in. diam.; scales and seeds many	1. Agathis.
Leaves small, scale-like. Cones small; scales 4–6; seeds 2–4 ..	2. Libocedrus.

ARAUCARIACEAE

See Trans. Linn. Soc. 8: 1807.

1. **AGATHIS** Salisb.

Evergreen monoecious or dioecious trees, often of great size. Leaves subopposite or alternate, broad, flat, coriaceous; nerves parallel. Male flowers solitary, axillary, peduncled; peduncle furnished with imbricate scales at the top. Anthers densely spirally arranged on a cylindrical column; cells 5–15, pendulous from the top of a rigid stipes. Female cones terminating short branchlets, broadly ovoid or globose; scales densely spirally arranged, tips broad. Ovules solitary or rarely 2 at the base of each scale and adnate to it, reversed. Mature cone globose or nearly so; scales closely imbricating and appressed, broad, flattened, hard but scarcely woody. Seeds 1 to each scale, very rarely 2, reversed, compressed, ovate or oblong; testa thin, produced into a membranous wing; albumen fleshy; cotyledons 2.

The genus *Agathis* contains seven or eight well-defined species, ranging from the Philippine Islands and Borneo to north-east Australia, western Polynesia, and New Zealand. Its present centre of distribution is evidently Polynesian, for there are 2 or possibly 3 species in New Caledonia, 1 in the New Hebrides, 1 in the Santa Cruz Group, and 1 in the Fiji Islands. It is somewhat remarkable that no species has yet been recorded from New Guinea or the Solomon Islands, but future explorations may remove this apparent anomaly. The single New Zealand species is purely endemic, although stated by Parlatore (D.C. Prodr. xvi, 2, 376) and Eichler (Naturl. Pflanzenf. ii, 1 abt. 67) to occur in Australia.

Students interested in the phylogeny, distribution, and morphology of *Agathis* and its close relative *Araucaria* should consult Seward and Ford's "Araucarieae, Recent and Extinct" (Trans. Roy. Soc. B. vol. 198 (1906) pp. 305–411).

1. **A. australis** *Salisb. in Trans. Linn. Soc.* viii (1807) 312.—A lofty forest-tree, with a straight columnar trunk and rounded somewhat bushy head, highly resiniferous in all its parts, usually ranging from 80–100 ft. high, with a trunk 4–10 ft. diam., but attaining an extreme height of 200 ft., with a trunk 15–22 ft. diam.; bark glaucous-grey, deciduous, falling off in large flat flakes. Leaves subopposite or alternate, sessile, very thick and coriaceous; of young trees lanceolate, 2–4 in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, gradually passing into those of mature trees, which are $\frac{3}{4}$–$1\frac{1}{2}$ in. long, linear-oblong or narrow obovate-oblong, obtuse. Flowers monoecious; males $\frac{3}{4}$–$1\frac{1}{2}$ in. long, cylindrical. Female cones obovoid in the flowering stage, becoming almost spherical when ripe, erect, 2–3 in. diam.; scales broad, flat, rather thin, falling away from the axis at maturity. Seeds 1 to each scale, ovate, compressed, winged.—*T. Kirk Forest Fl.* (1889) tt. 79–81; *Cheesem. Man. N.Z. Fl.* (1906) 645; *Ill. N.Z. Fl.* ii (1914) t. 184; *Cockayne Veg. N.Z.* (1921) tt. 30, 33. Dammara australis *Lamb. Pin.* ed. 2 (1828) 73; *A. Cunn. Precur.* (1838) n. 325; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 231; *Handb. N.Z. Fl.* (1864) 256. Podocarpus zamiaefolius *A. Rich. Fl. Nouv. Zel.* (1832) 360.

North Island: In forests from the North Cape southwards, attaining its extreme limit on the east coast inland from Maketu, in the Bay of Plenty; on the western side of the island in the vicinity of Kawhia Harbour. Sea-level to 2000 ft. *Kauri*, of the resin *kapia*.

The kauri-pine has given rise to an extensive literature. The first reliable popular account is that of Hochstetter ("New Zealand," pp. 140–50). For more strictly scientific information reference should be made to Mr. Kirk's "Forest Flora," and to Dr. Cockayne's "Botanical Survey of the Waipoua Kauri Forest." In my "Age and Growth of the Kauri" (Trans. N.Z. Inst. xlvi (1914) pp. 9–19) I have endeavoured to dispel the erroneous ideas entertained by previous writers as to the supposed slow rate of growth of the kauri; and in the "Illustrations of the New Zealand Flora," published in 1914, I have given a compendium of its history, and an account of its physiognomy and economic value. Lastly, Sir David Hutchins's recent publications on New Zealand forestry fully and clearly show the position of the kauri-pine as a timber-tree, and its suitability for planting in the future State forests of New Zealand.

2. **LIBOCEDRUS** Endl.

CUPRESSACEAE Syn. Con. 1907-52

Usually tall trees. Leaves opposite, small and scale-like, quadrifariously imbricate, either all equal and decussate or flattened on the branchlets, the lateral larger and keeled, those on the upper and lower faces of the branchlets smaller and flat. Flowers monoecious or dioecious; males terminal, solitary, oblong or ovoid or almost globose, consisting of a staminal column sessile within the uppermost leaves and bearing several or many decussately placed anthers; connective scale-like, ovate, subpeltate; anther-

cells usually 4, pendulous. Female cones oblong or ovoid, terminating short branchlets; scales 4 or 6, decussately opposite, the lowest pair smallest and sterile, the second pair with 2 erect collateral ovules at the base of each scale, the third pair when present sterile and connate. Scales of the mature cones persistent, gaping, indurated, mucronate or horned at the back towards the tip. Seeds solitary or rarely 2 at the base of each fertile scale, compressed, unequally winged.

A small genus of 9 species, with a very singular distribution, 1 being found in California, 2 in Chile, 2 in New Zealand, and 1 each in New Caledonia, New Guinea, China, and Japan.

Branchlets of mature trees more or less compressed, not tetragonous.
Cones ½ in. long .. .. 1. *L. Doniana.*

Branchlets of mature trees always tetragonous. Cones ¼–⅓ in. long .. 2. *L. Bidwillii.*

also

1. **L. Doniana** *Endl. Syn. Conif.* (1847) 43.—A tall forest-tree 30–70 ft. high or more, with a narrow tapering head; trunk 2–4 ft. diam.; bark stringy, falling off in long ribbons. Branchlets distichous; of young trees vertical, much flattened and compressed, $\frac{1}{5}$–$\frac{1}{4}$ in. broad; of old trees horizontal, less compressed, but not obviously tetragonous, $\frac{1}{10}$–$\frac{1}{8}$ in. broad. Leaves quadrifarious, the lateral larger, especially on young trees, where they are often ⅕ in. long, sheathing and connate at the base, spreading, acute; those on the upper and lower faces of the branchlets $\frac{1}{25}$–$\frac{1}{12}$ in. long, triangular, appressed to the branch. Male flowers about ¼ in. long, hardly broader than the branch; anthers 8–12; connective thin, ovate, subpeltate. Female cones ovoid, about ½ in. long, woody; scales 4, spreading, each with a sharp curved spine at the back. Seeds 2 to each cone.—*Hook. f. Handb. N.Z. Fl.* (1864) 256; *T. Kirk Forest Fl.* (1889) t. 82; *Cheesem. Man. N.Z. Fl.* (1906) 646. Thuja Doniana *Hook. in Lond. Journ. Bot.* i (1842) 571; *Hook. f. Fl. Nov. Zel.* i (1853) 231. Dacrydium plumosum *D. Don in Lamb. Pin.* ed ii, App. 143; *A. Cunn. Precur.* (1836) n. 330.

North Island: In forests from Mangonui southwards to Hawke's Bay and Taranaki, but often rare and local. South Island: Between Collingwood and West Wanganui, *H. J. Matthews* ex *Cockayne.* Sea-level to 2000 ft. *Kawaka; New Zealand Arbor-vitae.*

Wood dark-red, beautifully grained, said to be durable, but on account of its scarcity little used. Very young seedlings have narrow linear-subulate leaves spreading on all sides, but these soon pass into the quadrifarious stage.

2. **L. Bidwillii** *Hook. f. Handb. N.Z. Fl.* 257.—Very similar to *L. Doniana*, but usually smaller, seldom more than 50 ft. high, with a trunk 1½–3 ft. diam., in subalpine or cool peaty localities often reduced to a fastigiate bush or small tree 10–20 ft. high. Branchlets of young trees closely resembling those of *L. Doniana*, but rather narrower; of mature trees tetragonous, $\frac{1}{15}$–$\frac{1}{12}$ in. diam., densely clothed with almost uniform triangular acute closely appressed leaves. Female cones like those of *L. Doniana*, but smaller, ¼–⅓ in. long.—*T. Kirk Forest Fl.* (1889) t. 83; *Cheesem. Man. N.Z. Fl.* (1906) 647.

North and South Islands: From Te Aroha Mountain and Mount Egmont southwards to Foveaux Strait, not uncommon in hilly or mountain forests. 800–4000 ft. *Pahautea; Cedar.*

Often confounded with the previous species, but the obviously tetragonous branchlets of the mature tree, with almost uniform leaves, are characteristic and readily distinguish it. Wood soft, red, straight in the grain, easily split, and apparently of great durability, but of low specific gravity and somewhat brittle.

Family VII. **TAXACEAE.** PODOCARPACEAE

Trees or shrubs, usually resinous, mostly evergreen, and always so in the New Zealand species. Leaves linear or scale-like, or in some exotic genera broad and fan-like; in *Phyllocladus* replaced by broad flattened branchlets which are toothed or lobed. Flowers usually dioecious; perianth wanting in both sexes. Male flowers a small cone or catkin of stamens placed on a central axis, each stamen in the axil of a scale. Anther-cells usually two. Female flowers consisting of one or few ovules borne on the upper face of a scale, axillary or terminal, not associated into a cone. Fruit nut-like, often with an aril at the base, or the axis below the ovule with the scales upon it often becoming coloured and succulent when the fruit is ripe.

A well-known family, comprising 10 genera and 100 species. It is more plentiful in the Southern Hemisphere than in the Northern, although the common yew (*Taxus baccata*) and a few other species are found therein. The three genera native to New Zealand have a wide geographical range, and contain several important timber-trees.

Leaves small, linear and flat or scale-like. Peduncle of fruit, together with the bracts, usually fleshy and enlarged. Ovule reversed	1. PODOCARPUS.
Leaves usually dimorphic, of mature trees small and scale-like. Peduncle of fruit dry or fleshy. Ovule at first reversed but ultimately erect. Seed seated in a membranous or fleshy aril ..	2. DACRYDIUM.
Branchlets expanded into broad and flat coriaceous leaf-like cladodes. True leaves reduced to minute scales. Ovule erect ..	3. PHYLLOCLADUS.

1. **PODOCARPUS** L'Herit. L.Hér. Sert. Syncp. 350.

Trees or shrubs. Leaves alternate or opposite, scattered or imbricate or distichous, very diverse in size and shape. Flowers dioecious or rarely monoecious; males solitary or in fascicles of 2–5, or laxly spicate along an elongated rhachis, usually stipitate, the stipes furnished with imbricate bracts. Staminal column elongate, cylindric; anthers sessile, densely spirally crowded; cells 2, parallel, dehiscing longitudinally; connective usually prolonged into a short claw. Female flowers solitary or occasionally geminate, very rarely spicate; bracts or scales few, adnate with the rhachis into a swollen fleshy or succulent peduncle or "receptacle"; ovuliferous scale springing from the receptacle, ovoid, fleshy, bearing a single reversed ovule. Seeds globose or ovoid, seated on the enlarged receptacle, drupaceous or nut-like. Cotyledons 2.

About 60 species are known, scattered through the tropical and subtropical regions of the Old World, from Japan and China southwards to New Zealand and South Africa, also in most parts of South America; wanting in Europe, North America, North Africa, and western Asia. The New Zealand species are all endemic.

A. Flowers axillary.

* Male flowers solitary or 2–4 at the tip of a common peduncle.

Tree 40–100 ft.; bark thick. Leaves ½–1 in., linear, rigid and coriaceous, pungent. Male flowers subsessile. Nut small, obtuse	1. *P. totara.*
Tree 25–60 ft.; bark thin, papery. Leaves ¾–1½ in., linear, rigid and coriaceous, pungent. Male flowers evidently stalked. Nut acute	2. *P. Hallii.*
Erect shrub 3–10 ft.; branches slender. Leaves lax, ½–1 in. long, narrow-linear, pungent, thin	3. *P. acutifolius.*
Diffuse or prostrate shrub 2–8 ft.; branches stout. Leaves close-set, ¼–⅔ in., linear-oblong, obtuse, thick and coriaceous	4. *P. nivalis.*

Tree 50–80 ft. Leaves distichous, $\frac{1}{2}$–$\frac{3}{4}$ in., linear, acute, falcate. Fruit large, broadly oblong, succulent, $\frac{3}{4}$ in. long .. .. 5. *P. ferrugineus.*

** Male flowers numerous, spiked.

Tree 40–80 ft. Leaves distichous, $\frac{1}{3}$–$\frac{1}{2}$ in., linear, obtuse. Fruit globose, succulent, $\frac{1}{4}$–$\frac{1}{3}$ in. diam. .. .. 6. *P. spicatus.*

B. Flowers terminating the branchlets.

Tree 80–120 ft. Leaves of young trees distichous, $\frac{1}{4}$ in.; of mature plants imbricate all round, $\frac{1}{12}$–$\frac{1}{8}$ in., subulate-lanceolate, acuminate 7. *P. dacrydioides.*

1. **P. totara** *D. Don in Lamb. Pin.* ed. ii (1832) 189.—A lofty forest-tree 40–80 ft. or even 100 ft. high; trunk 2–6 ft. diam.; bark thick, furrowed, stringy and papery, capable of removal in large sheets. Leaves dull brownish-green, spreading on all sides or obscurely distichous, $\frac{1}{2}$–1 in. long, linear, straight or slightly falcate, acute, pungent, rigid and coriaceous, midrib obscure. Flowers dioecious. Males $\frac{1}{2}$–$\frac{3}{4}$ in. long, stout, obtuse, axillary, solitary or 2–3 together at the top of a very short stout peduncle or almost sessile; each flower with 4 bracts at the base. Anthers numerous, crowded; connective toothed at the tip. Female flowers axillary, solitary or geminate at the top of a short swollen peduncle. Fruit ovoid-oblong, rounded at the tip; peduncle usually much enlarged, red, succulent; but occasionally dry and shrivelled.—*A. Cunn. Precur.* (1836) n. 328; *Raoul Choix* (1846) 41; *Hook. Lond. Journ. Bot.* i (1842) 572, t. 19; *Hook. f. Fl. Nov. Zel.* i (1853) 233; *Handb. N.Z. Fl.* (1864) 258; *T. Kirk Forest Fl.* (1889) t. 115; *Pilger in Pflanzenr.* iv, 5 (1903) 84; *Cheesem. Man. N.Z. Fl.* (1906) 648; *Ill. N.Z. Fl.* ii (1914) t. 185; *Cockayne Veg. N.Z.* (1921) t. 28. P. Bidwillii *Hoibrenk in Endl. Con.* (1847) 213. P. Cunninghamii *Col. Visit to Ruahine Range* (1844) 58.

North and South Islands: Common in forests from the North Cape to the south-east of Otago. Sea-level to 2000 ft. *Totara.*

A magnificent tree, scarcely less valuable than the kauri; but, unlike it, generally distributed throughout the colony. Wood red, straight-grained, compact, extremely durable, much used for all kinds of building purposes and constructive works. From its power of resisting the attacks of the teredo it is particularly valuable for the piles of wharves, &c. The huge war-canoes of the Maoris, which were often over 80 ft. in length, were carved from the trunks of totara-trees, and it was also the favourite timber for their carved houses.

2. **P. Hallii** *T. Kirk Forest Fl.* (1889) t. 9, 9A.—Very closely allied to *P. totara*, and perhaps a mere variety, but smaller, 25–60 ft. high; trunk rarely exceeding 3 ft. diam.; bark thin, papery; branches of young trees weak, slender. Leaves of young plants usually distichous, spreading, 1–1$\frac{1}{2}$ in. long, narrow linear-lanceolate; of mature trees inserted all round the branches, close-set, $\frac{3}{4}$–1 in. long, linear or linear-lanceolate, acute, pungent, rigid and coriaceous, midrib somewhat prominent beneath. Flowers dioecious. Male flowers as in *P. totara*, but usually solitary and distinctly peduncled. Female flowers frequently geminate on the short peduncle. Fruit narrow-ovoid, pointed; peduncle usually enlarged and succulent.—*Cheesem. Man. N.Z. Fl.* (1906) 648. P. totara *var.* Hallii *Pilger in Pflanzenr.* iv, 5 (1903) 84.

North and South Islands, Stewart Island: In forests from Kaitaia and Mangonui southwards, not uncommon. Sea-level to 3500 ft.

I am very doubtful as to this being more than a variety of *P. totara*, which is the view held by Dr. Pilger. Young plants are easily distinguished by the weak and often flexuous branches and larger leaves; but it must be confessed that the mature

foliage so closely resembles that of *P. totara* that it is often difficult to separate the two plants by that character alone. The thin papery bark is, however, unmistakable. I fear that the shape of the fruit and the length of the peduncle of the male flower are subject to variation. The wood is similar to that of *P. totara*, but is said to be inferior in durability. Mr. Kirk suggests that Colenso's *P. Cunninghamii* may be identical with *P. Hallii;* but the type specimen in Mr. Colenso's herbarium appears to be *P. totara.*

3. **P. acutifolius** *T. Kirk in Trans. N.Z. Inst.* xvi (1884) 370, t. 26.—An erect much-branched shrub 5–30 ft. high; branches slender, erect. Leaves usually rather lax, spreading $\frac{1}{3}$–1 in. long, linear, straight, acuminate and pungent, sessile or nearly so, green, coriaceous; midrib indistinct; margins slightly recurved. Flowers dioecious. Males $\frac{1}{3}$–$\frac{1}{2}$ in. long, solitary or in fascicles of 2–4 at the top of an erect peduncle about $\frac{1}{2}$ in. long, each flower with 4 scarious acuminate bracts at its base, forming a quasi-involucre at the top of the peduncle. Anthers numerous, closely packed; connective obtuse. Female flowers minute, axillary, solitary or very rarely geminate at the top of a short swollen peduncle. Fruit small, ovoid, seated on the enlarged and fleshy bright-red peduncle.—*T. Kirk Forest Fl.* (1889) t. 39; *Pilger in Pflanzenr.* iv, 5 (1903) 84; *Cheesem. Man. N.Z. Fl.* (1906) 649.

South Island: Marlborough—*J. Rutland!* Mount Duppa, *J. H. Macmahon!* Nelson—Lake Rotoiti and upper part of the Buller Valley, *T. Kirk! T. F. C.;* Hope Valley, *T. F. C.* Westland—Lake Brunner and Franz Josef Glacier, and common southwards to the Cook River, *Cockayne!*

Allied to *P. nivalis,* but at once recognized by the erect slender habit and narrow pungent leaves. From *P. totara* it is separated by the small size, much more slender habit, and narrower thinner leaves.

4. **P. nivalis** *Hook. Ic. Plant.* (1843) t. 582.—A much-branched erect or prostrate shrub 2–8 ft. high; branches wide-spreading, often rooting at the base. Leaves close-set, sessile, not distichous, spreading or recurved, $\frac{1}{3}$–$\frac{2}{3}$ in. long, linear to linear-oblong or narrow linear-obovate, obtuse, apiculate, narrowed to the base, very thick and coriaceous, midrib prominent beneath, margins thickened. Flowers dioecious. Males axillary, solitary or 2–4 at the top of a slender peduncle, variable in length, very slender, $\frac{1}{4}$–1 in. long. Anthers very numerous, often laxly placed; connective obtuse. Female flowers solitary, axillary, seated on the top of a short swollen peduncle. Fruit a small oblong-ovoid nut; peduncle much enlarged, fleshy and succulent, bright-red, usually with 2 acute projections at the top (adnate bracts), 1 on each side of the nut.—*Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 232; *Handb. N.Z. Fl.* (1864) 257; *T. Kirk Forest Fl.* (1889) t. 40; *Pilger in Pflanzenr.* iv, 5 (1903) 85; *Cheesem. Man. N.Z. Fl.* (1906) 649; *Ill. N.Z. Fl.* (1914) t. 186. P. montanus *Col. in Trans. N.Z. Inst.* xxvii (1895) 395.

Var. **erectus** *Cockayne in Trans. N.Z. Inst.* xlviii (1916) 199.—Erect, 4–7 ft. high, not prostrate. Leaves larger, sometimes nearly 1 in. in length.

North and South Islands: Abundant in subalpine localities from the summit of Moehau (Cape Colville) and Tongariro southwards to Foveaux Strait. Usually from 2000 to 5500 ft., but descends almost to sea-level near Okarito and elsewhere in Westland. Var. *erectus:* Nelson—Mount Owen and Mount Percival, 3000 ft., *T. F. C.* Canterbury—Cass River, *Cockayne.*

A distinct little plant. Mr. Kirk has well pointed out that it is serviceable from its spreading and rooting habit, which helps to bind the loose surface of steep mountain-slopes.

5. **P. ferrugineus** *D. Don in Lamb. Gen. Pinet.* ed. ii (1832) 189.—A tall forest-tree 50–80 ft. high with a rather narrow round-topped head; trunk 1–3 ft. diam.; bark greyish-brown or almost black, scaling off in large flakes. Leaves distichous, close-set, spreading, $\frac{1}{2}$–$\frac{3}{4}$ in. long, linear, falcate, acute or subacute, 1-nerved, margins recurved, red-brown when dry; those of young plants longer, narrower, and more acute. Flowers dioecious. Males axillary, solitary, sessile, cylindric, equalling or rather longer than the leaves. Anthers numerous, closely packed; connective obtuse. Female flowers solitary or very rarely geminate at the top of a curved peduncle clothed with minute scale-like bracts. Fruit large, broadly oblong, drupaceous, $\frac{3}{4}$ in. long, reddish-purple with a glaucous bloom, top of the peduncle not enlarged nor succulent.—*A. Cunn. Precur.* (1836) n. 327; *Raoul Choix* (1846) 41; *Hook. Ic. Plant.* (1843) t. 543; *Hook. f. Fl. Nov. Zel.* i (1853) 232; *Handb. N.Z. Fl.* (1864) 257; *T. Kirk Forest Fl.* (1889) t. 84; *Pilger in Pflanzenr.* iv, 5 (1903) 66; *Cheesem. Man. N.Z. Fl.* (1906) 650.

North and South Islands, Stewart Island: Abundant in forests throughout. Sea-level to 3000 ft. *Miro; Toromiro; Black-pine.*

Wood strong, hard and compact, straight-grained, not durable in exposed situations. The fleshy drupes form the chief food of the wood-pigeon during the winter months.

6. **P. spicatus** *R. Br. in Benn. Pl. Jav. Rar.* (1838) 40.—A tall round-headed forest-tree 40–80 ft. high; branches numerous, crowded, erect; trunk 2–4 ft. diam.; bark black or bluish-black, scaling off in large flakes. Young plants with long slender flexuous and pendulous branches, clothed towards the tips with reddish-brown leaves. Leaves of mature plants distichous, $\frac{1}{3}$–$\frac{1}{2}$ in. long, linear, straight or slightly falcate, obtuse or apiculate, coriaceous, green above, glaucous beneath. Flowers dioecious. Males numerous, $\frac{1}{5}$–$\frac{1}{3}$ in. long, linear, obtuse, horizontal, arranged in axillary spikes. Anthers closely packed; connective ovate, acute. Female flowers in 3–8-flowered spikes. Fruit black or nearly so, globose, succulent, $\frac{1}{4}$–$\frac{1}{3}$ in. diam.; fleshy receptacle wanting.—*Hook. Ic. Plant.* (1843) t. 543; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 232; *Handb. N.Z. Fl.* (1864) 258; *T. Kirk Forest Fl.* (1889) t. 4, 5; *Pilger in Pflanzenr.* iv, 5 (1903) 65; *Cheesem. Man. N.Z. Fl.* (1906) 650. P. matai *Lamb. ex Hook. f. Handb. N.Z. Fl.* (1864) 741. Dacrydium taxifolium *Banks and Soland. ex Lamb. Pin.* ed. 2 (1824) 119. D. Mai *A. Cunn. Precur.* (1836) n. 329. Prumnopitys spicata *Kent in Veitch Man. Con.* ed. 2 (1900) 157.

North and South Islands, Stewart Island: Not uncommon in forests from the North Cape southwards. Sea-level to 2000 ft. *Matai; Mai; Black-pine.*

A very distinct species, at once recognized by the spicate flowers and globose fruit. Wood brownish, hard, heavy, close-grained, of great strength and durability. This and the preceding differ from the remaining New Zealand species in wanting the succulent receptacle to the fruit.

7. **P. dacrydioides** *A. Rich. Fl. Nouv. Zel.* (1832) 358, t. 39.—A lofty tree 80–100 ft. or 120 ft. high, in swampy localities often growing gregariously and forming dense forests; trunk 2–5 ft. diam. Leaves of two forms: those of young trees distichous, $\frac{1}{6}$–$\frac{1}{4}$ in. long, linear, falcate, upturned and acuminate at the tip, decurrent at the base, flat, nerveless; of mature trees inserted all round the branch and appressed to it, imbricated, $\frac{1}{12}$–$\frac{1}{8}$ in. long, subulate-lanceolate, acuminate, keeled. Flowers dioecious. Males solitary, terminal, $\frac{1}{6}$–$\frac{1}{4}$ in. long; anthers crowded; connective ovate, acute. Female flowers minute, solitary, terminating the branchlets; peduncle and bracts

swollen. Fruit a black ovoid nut about $\frac{1}{6}$ in. long, seated on the greatly enlarged bright-red succulent peduncle.—*Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 233; *Handb. N.Z. Fl.* (1864) 258; *T. Kirk Forest Fl.* (1889) t. 31, 32; *Pilger in Pflanzenr.* iv, 5 (1903) 57; *Cheesem. Man. N.Z. Fl.* (1906) 651; *Cockayne Veg. N.Z.* (1921) t. 27. P. thuyoides *R. Br. in Benn. Pl. Jav. Rar.* (1838) 41. Dacrydium excelsum *A. Cunn. Precur.* (1838) n. 214. D. ferrugineum *Van Houtte ex Gord. Pin.* (1858) 590.

North and South Islands, Stewart Island: In lowland forests from the North Cape southwards, abundant. Sea-level to 2000 ft. *Kahikatea; Kahika; White-pine,*

The kahikatea, or white-pine, as it is usually called in the south of New Zealand, is probably the tallest tree in the Dominion. Two specimens measured by Sir David Hutchins in the forests of Westland had heights of 210 ft. and 184 ft. respectively, each having a diameter of about 5 ft. Another example noticed at Kakahi, a little to the south of Taumarunui, on measurement by Mr. Phillips Turner proved to be 195 ft. high. No doubt taller trees will yet be observed. The wood is white or pale-yellow, tough and compact, straight-grained and easily worked, but unfortunately not durable when in contact with the ground or where regularly exposed to damp. It is very suitable for inside work of all kinds, but is liable to the attacks of a small boring-beetle.

2. **DACRYDIUM** Soland.

Trees or shrubs. Leaves usually dimorphic; of old trees small and scale-like, closely imbricate; of young trees or of the lower branches of old ones longer and narrower, spreading, linear or linear-subulate. Flowers dioecious or more rarely monoecious. Males solitary at the tips of the branchlets and sessile amongst the uppermost leaves. Staminal column oblong or cylindrical; anthers sessile, spirally imbricate; cells 2, globose, contiguous, deflexed; connective prolonged into a terminal claw or spur. Female flowers at or near the tips of the branchlets, the bracts hardly differing from the foliage-leaves. Ovuliferous scale free, at length exceeding the bract; ovule solitary, at first more or less reversed, at length erect. Seeds ovoid, nut-like, seated within a membranous or fleshy cup-shaped aril. Cotyledons 2.

About 16 species are known, natives of the Malay Peninsula, Borneo, Australia and Tasmania, New Caledonia, New Zealand, and Chile. All the species found in New Zealand are endemic.

A. Leaves of young plants spreading, linear, flat, abruptly passing into the smaller mature scale-like leaves. Nuts 1–5 together.

Height 50–80 ft. Leaves of young trees 1–1½ in., shortly petiolate. Mature branchlets nearly terete. Nuts 1–5, usually 3–4 .. 1. *D. Kirkii.*

Height 15–30 ft. Leaves of young trees $\frac{1}{2}$–$\frac{3}{4}$ in., shortly petiolate. Mature branchlets tetragonous, stout. Nuts 1–2 .. .. 2. *D. biforme.*

Height 2–10 ft. Leaves of young trees $\frac{1}{4}$–$\frac{1}{3}$ in., sessile. Mature branchlets tetragonous. Nuts 1–2 .. .. .. 3. *D. Bidwillii.*

B. Leaves of very young plants spreading, linear, terete, passing by gradual transitions into the mature scale-like imbricating leaves. Nuts usually solitary.

Height 60–100 ft.; branchlets pendulous. Leaves of mature plants $\frac{1}{12}$–$\frac{1}{8}$ in., subulate, trigonous. Receptacle below the female flower often fleshy .. .. 4. *D. cupressinum.*

Height 20–40 ft.; branchlets not pendulous. Leaves of young trees (second stage) trigonous, not distichous. Mature branchlets $\frac{1}{12}$ in. diam.; leaves $\frac{1}{15}$–$\frac{1}{10}$ in. long, obtuse. Nuts solitary; aril short .. .. 5. *D. intermedium.*

Height 20–50 ft., branchlets not pendulous. Leaves of young trees (second stage) flat, triangular, decurrent, often distichous. Mature branchlets $\frac{1}{20}$–$\frac{1}{15}$ in. diam.; leaves $\frac{1}{20}$–$\frac{1}{12}$ in. long, subacute. Nuts often 2; aril large, sometimes reaching the middle of the nut .. .. 6. *D. Colensoi.*

Prostrate, 3–18 in. long; branches straggling. Leaves of mature plants either spreading, $\frac{1}{8}$–$\frac{1}{12}$ in. long, or imbricating, $\frac{1}{20}$–$\frac{1}{4}$ in... 7. *D. laxifolium.*

D. excelsum A. Rich. Fl. N.Z. 358 t 39. acc. to. P. excelsa A. Donin Lamb. Pin. Ed. ii, app. 1828. A. Cunn. as. Dacrydium Druce Rep. :640.

1. **D. Kirkii** *F. Muell. ex Parl. in D.C. Prodr.* xvi, ii (1868) 495.—A tall tree 50–80 ft. high; trunk 2–3 ft. diam.; bark greyish-brown; lower branches spreading, upper more erect. Leaves of two forms: those of young trees and on the lower branches of old ones large, erecto-patent, 1–1½ in. long, linear, subacute, narrowed into a very short twisted petiole, flat, pale-green, coriaceous; midrib distinct; margins slightly cartilaginous. Leaves of the upper and fertile branches small and scale-like, densely quadrifariously imbricate and appressed to the almost terete branchlets, $\frac{1}{12}$–$\frac{1}{8}$ in. long, ovate-rhomboid, obtuse, thick and coriaceous, obtusely keeled on the back; margins thin, membranous. Flowers dioecious. Males solitary, terminal, sessile, $\frac{1}{8}$–$\frac{1}{4}$ in. long. Females at the tips of the branchlets, forming a short oblong head $\frac{1}{4}$–$\frac{1}{2}$ in. long. Nuts 1–5 (usually 3–4), oblong, obtuse, compressed, striate, about $\frac{1}{8}$ in. long.—*Hook. f. Ic. Plant.* (1877) t. 1219; *T. Kirk in Trans. N.Z. Inst.* x (1878) 390, t. 19; *Forest Fl.* (1889) t. 97; *Pilger in Pflanzenr.* iv, 5 (1903) 46; *Cheesem. Man. N.Z. Fl.* (1906) 652.

North Island: In forests from Hokianga to the Manukau Harbour, rare and local. Whangaroa, *Hector* and *Buchanan!* between Hokianga and the Northern Wairoa, *Petrie! Cockayne;* between the Bay of Islands and Whangarei, *R. Mair! T. F. C.;* Great Barrier Island, *T. Kirk!* Titirangi (near Auckland), *T. F. C.* Sea-level to 2000 ft. *Monoao.*

A handsome tree, distinguished from its immediate allies by the large size, the large leaves of the young trees and lower branches of the old ones, the almost terete fertile branchlets, and the usually numerous nuts. The transition from the long linear leaves of the young state to the small scale-like leaves of the old plant is most abrupt, Both forms can often be found on the same branch. The wood is pale brownish-red. strong and compact, and exceedingly durable.

(Hook.)

2. **D. biforme** *Pilger in Pflanzenr.* iv, 5 (1903) 45.—A small tree 15–30 ft. or 40 ft. high, in alpine localities often dwarfed to a few feet; trunk short, 1–2 ft. diam.; bark dark-brown; branches stout, clothed with the persistent and indurated leaves; mature branchlets tetragonous. Leaves of two forms: those of young plants and on the lower branches of old ones spreading, $\frac{1}{3}$–$\frac{3}{4}$ in. long, $\frac{1}{15}$–$\frac{1}{12}$ in. broad, linear, acute, narrowed into a very short broad often twisted petiole, flat, coriaceous; midrib distinct. Leaves of old or fertile branchlets small and scale-like, densely quadrifariously imbricate and closely appressed, $\frac{1}{20}$–$\frac{1}{12}$ in. long, triangular or rhomboid-triangular, obtuse, very thick and coriaceous, stoutly and prominently keeled on the back. Flowers dioecious. Males solitary, terminal, sessile, about $\frac{1}{8}$ in. long; anthers 4–6; connective ovate, obtuse. Female flowers near the tips of the branchlets. Nuts 1–2 (usually solitary), oblong, obtuse, striate, compressed, about $\frac{1}{10}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 653. D. Colensoi *Hook. f. Fl. Nov. Zel.* i (1853) 234, *and Handb. N.Z. Fl.* (1864) 259 (*not of Hook. Ic. Plant.* t. 548); *T. Kirk in Trans. N.Z. Inst.* x (1878) 390; *Forest Fl.* (1889) t. 96. Podocarpus(?) biformis *Hook. Ic. Plant.* (1843) t. 544.

North Island: Mountain districts from Tongariro and the Ruahine Mountains southwards, not common. South Island, Stewart Island: Not uncommon in mountain forests throughout. Usually from 2000 to 4500 ft., but descends to sea-level in the south-west of Otago and on Stewart Island. *Yellow-pine; Tar-wood.*

This is for the most part the *D. Colensoi* of the Flora and the Handbook; but, as shown elsewhere, not the plant originally described under that name by Sir W. J. Hooker.

3. **D. Bidwillii** *Hook. f. ex T. Kirk in Trans. N.Z. Inst.* x (1878) 388.—A closely branched erect or prostrate shrub 2–10 ft. high; lower branches spreading, sometimes reclinate and rooting; upper more erect,

frequently giving a pyramidal form to the plant; trunk short, 3–9 in. diam. Leaves of two forms: those of young plants and on the lower branches of old ones spreading, crowded, $\frac{1}{4}$–$\frac{1}{3}$ in. long, linear, obtuse, sessile by a comparatively broad base, flat, coriaceous; midrib usually distinct. Leaves on the upper and fertile branches small and scale-like, densely quadrifariously appressed, $\frac{1}{25}$–$\frac{1}{12}$ in. long, triangular, obtuse, very thick and coriaceous. Flowers dioecious. Males solitary, terminal, sessile, $\frac{1}{10}$–$\frac{1}{8}$ in. long. Female flowers near the tips of the branchlets. Nuts 1 or 2, small, striate, compressed, obtuse, about $\frac{1}{12}$ in. long.—*T. Kirk Forest Fl.* (1889) t. 37; *Pilger in Pflanzenr.* iv, 5 (1903) 46; *Cheesem. Man. N.Z. Fl.* (1906) 653; *Ill. N.Z. Fl.* ii (1914) t. 187.

Var. *a*, **erecta** *T. Kirk.*—Main branches ascending or erect, giving the plant a pyramidal or almost fastigiate outline.

Var. *b*, **reclinata** *T. Kirk.*—Main branches prostrate or horizontal.

North Island: Summit of Moehau (Cape Colville), *Adams!* Tiroa (near Mangapeehi), *A. Wilson* and *J. C. Rolleston!* Tongariro and neighbouring mountains, *Spencer! T. F. C., Cockayne;* Lake Rotoaira, *Tryon!* Ruahine Mountains, *Colenso! B. C. Aston!* Kaimanawa Mountains, *B. C. Aston!* South Island, Stewart Island: Not uncommon in subalpine localities throughout. Usually from 2000 to 4500 ft., but descending to sea-level in Stewart Island.

A near ally of *D. biforme*, principally differing in the smaller size and remarkably distinct habit, in the smaller linear leaves, which are sessile by a broad base, and in the more slender branchlets and smaller nut. When seen growing it is distinguished without any difficulty, but dried specimens not showing the linear leaves are easily confounded with slender states of *D. biforme*.

also Rudr (1786) 92. n. 561.

4. **D. cupressinum** *Soland. ex Forst. f. Pl. Escul.* (1786) 80.—A tall forest-tree 60–80 ft. or even 100 ft. high, with a comparatively small round-topped head when mature, but pyramidal when young, with very long pale-green pendulous branches; trunk 2–5 ft. diam.; bark dark-brown, scaling off in large flakes. Leaves imbricating all round the branch; of young trees lax, ascending, $\frac{1}{6}$–$\frac{1}{4}$ in. long, linear-subulate, acute, almost acerose, decurrent at the base; gradually passing into those of the mature trees, which are much smaller and more closely set and more appressed to the branch, $\frac{1}{12}$–$\frac{1}{8}$ in. long, linear, acute, trigonous, keeled at the back. Flowers dioecious. Males solitary or rarely 2 together at the tips of the branchlets, oblong; connective broadly ovate, acuminate. Female flowers solitary on the curved tips of the branchlets. Nut ovoid, barely compressed, about $\frac{1}{8}$ in. long, seated within a cup-shaped aril; receptacle and bracts sometimes enlarged, fleshy and coloured, at other times remaining dry and unaltered.—*A. Rich. Fl. Nouv. Zel.* (1832) 361; *A. Cunn. Precur.* (1838) n. 332; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 233; *Handb. N.Z. Fl.* (1864) 258; *T. Kirk Forest Fl.* (1889) t. 18, 22; *Pilger in Pflanzenr.* iv, 5 (1903) 63; *Cheesem. Man. N.Z. Fl.* (1906) 654; *Cockayne Veg. N.Z.* (1921) t. 15. Thalamia cupressina *Spreng. Syst.* (1826) 890.

North and South Islands, Stewart Island: Abundant in forests throughout. Sea-level to 2500 ft. *Rimu; Red-pine.*

A well-known tree, the young state of which, with its graceful shape and pale-green pendent branches, is perhaps as beautiful and attractive as any tree in New Zealand. The wood is deep-red, strong, hard, and heavy, but often twisted in the grain. It is largely used for building purposes of all kinds and for the manufacture of furniture, but is not nearly as durable as either kauri or totara. In height *D. cupressinum* is but little inferior to the kauri or kahikatea. Two examples measured by Sir David Hutchins in the Westland forests reached heights of 198 ft. and 168 ft. respectively.

5. **D. intermedium** *T. Kirk in Trans. N.Z. Inst.* x (1878) 386, t. 20.—A small tree 20–40 ft. high or more; branches spreading; trunk 1–2 ft. diam., rarely more; bark brownish-grey. Leaves of very young plants lax, spreading, $\frac{1}{3}$–$\frac{1}{2}$ in. long, narrow linear-subulate, acute, curved, terete; gradually passing into the leaves of young trees, which are closer-set, squarrose or erecto-patent, $\frac{1}{8}$–$\frac{1}{4}$ in. long, broadly subulate, trigonous, acute. These again pass by imperceptible transitions into those of mature trees, which are densely quadrifariously imbricate and appressed to the branch, $\frac{1}{15}$–$\frac{1}{10}$ in. long, ovate-triangular or rhomboid, obtuse, keeled, very thick and coriaceous. Flowers dioecious or rarely monoecious. Males usually abundantly produced, solitary, terminal, sessile, about $\frac{1}{4}$ in. long; anthers numerous; connective broadly triangular, acute. Female flowers solitary at the tips of the branchlets. Nut oblong, obtuse or apiculate, faintly striate, not compressed, $\frac{1}{8}$–$\frac{1}{6}$ in. long, enclosed at the base in a short cup-shaped aril.—*T. Kirk Forest Fl.* (1889) t. 86; *Pilger in Pflanzenr.* iv, 5 (1903) 51; *Cheesem. Man. N.Z. Fl.* (1906) 655; *Ill. N.Z. Fl.* (1914) t. 188.

North Island: Between the Bay of Islands and Whangarei, *R. Mair!* Great Barrier Island, *T. Kirk!* from Cape Colville to the Thames goldfields and Te Aroha, *T. Kirk! Adams! T. F. C.;* from Lake Taupo to the Ruahine Mountains and the Tararua Range, *Colenso! T. F. C., Tryon! R. Mair! Cockayne! A. Hamilton! B. C. Aston.* South Island, Stewart Island: Not uncommon in mountain forests, chiefly on the western side of the island. Sea-level to 4000 ft. *Mountain-pine; Yellow Silver-pine.*

Wood reddish-yellow, highly resinous and very inflammable, of great strength and durability; largely used in Westland (together with *D. Colensoi*) for railway sleepers, telegraph-poles, &c.

6. **D. Colensoi** *Hook. Ic. Plant.* (1843) t. 548 (*not of Hook. f.*).—A small tree 20–40 ft. high or more, very similar in mode of growth to *D. intermedium*, but rather taller and more conical, with a straighter and cleaner trunk; branchlets more slender, often flexuous, $\frac{1}{20}$–$\frac{1}{15}$ in. diam. Leaves of very young plants lax, spreading, $\frac{1}{4}$–$\frac{1}{2}$ in. long, narrow linear-subulate, terete, decurrent at the base; gradually passing into the leaves of young trees, which are more closely set, $\frac{1}{8}$–$\frac{1}{6}$ in. long, lanceolate or narrow-triangular, acute, falcate, flat, decurrent at the base, often more or less spreading in one plane, giving the branchlets a distichous appearance. These pass by insensible gradations into those of mature trees, which are small and scale-like, densely quadrifariously imbricate and appressed to the branch, $\frac{1}{20}$–$\frac{1}{12}$ in. long, rhomboid, obtuse or subacute, thick and coriaceous, keeled, apex often incurved. Flowers dioecious. Males solitary, terminal, sessile, $\frac{1}{8}$–$\frac{1}{6}$ in. long; anthers numerous; connective broad, triangular, acute. Female flowers at the tips of the branchlets. Nuts 1 or 2, oblong, obtuse, not compressed, about $\frac{1}{12}$ in. long, enclosed for $\frac{1}{3}$ of their length or more in a lax cup-shaped aril.—*Pilger in Pflanzenr.* iv, 5 (1903) 51; *Cheesem. Man. N.Z. Fl.* (1906) 655. D. Westlandicum *T. Kirk in Trans. N.Z. Inst.* x (1878) 387, t. 18; *Forest Fl.* (1889) t. 85; *Hook. f. Ic. Plant.* (1877) t. 1218.

North Island: Between Mangonui and Kaitaia, *H. Carse!* Waipoua Forest, *Cockayne;* Whangaroa, *Hector!* between the Bay of Islands and Whangarei, *Colenso;* Great Barrier Island, *T. Kirk!* Waimarino Forest, *T. Kirk, T. F. C.;* forests round the base of Ruapehu and adjoining mountains, *T. F. C., E. Phillips Turner, Cockayne.* South Island: Not uncommon along the West Coast from Collingwood to Martin's Bay, *T. Kirk! Spencer! W. Townson! J. W. Brame! Helms!* &c. Sea-level to 3000 ft. *Silver-pine.*

Very close to the preceding; but the leaves of the young trees are much flatter, more decurrent, and often distichous; the mature leaves are smaller and the branchlets more slender; and the nuts are smaller, often 2 together, and are enclosed sometimes almost as far as the middle in the unusually well-developed aril. The wood is yellowish-white, straight-grained, strong and compact, very durable. It is exported from Westland to all parts of the colony for railway-sleepers, and has been used with good results for the framework of bridges, wharves, &c.

D. Colensoi is a species which has been much misunderstood. By nearly all writers the name has been applied to the mountain-plant originally described by Sir W. J. Hooker in the "Icones Plantarum" (t. 544) as *Podocarpus*(?) *biformis*, the *Dacrydium biforme* of this work, although the two species are in reality totally different. The mistake appears to have originated in the "Flora Novæ Zelandiæ," where Sir J. D. Hooker quoted *Podocarpus*(?) *biformis* as a synonym of *D. Colensoi*. His description is based entirely on *D. biforme*, and the localities given (Dusky Bay, *Menzies;* Tongariro and Ruahine Mountains, *Colenso;* mountains near Nelson, *Bidwill*) all unquestionably refer to the same plant. It is curious that, although the original plate of *D. Colensoi* is cited in the Flora, no reference is given to the locality in which the species was first discovered. From a letter of Mr. Colenso's sent with the type specimens, and published in the *London Journal of Botany* (vol. i, p. 301), this appears to have been the rough forest country between Whangarei and the Bay of Islands—a station quite 250 miles to the north of the northern limit of *D. biforme*. Early in the preparation of this work a comparison of the original descriptions and figures convinced me that, although the plate of *Podocarpus*(?) *biformis* was a very faithful representation of the plant to which all New Zealand botanists, following the example of Sir J. D. Hooker, at that time assigned the name of *Colensoi*, it by no means corresponded with the original plate of *D. Colensoi*. Not only did the two plants differ in a marked degree in habit and foliage, but the figures given of the fruit of *D. Colensoi* were so unlike that of *D. biforme* as to make their specific distinctness beyond all doubt. It therefore became necessary to restore *Podocarpus*(?) *biformis* to the rank of a species under the name of *D. biforme*. Further study of the original plate of *D. Colensoi* made it clear that two subsequently described species—*D. intermedium* and *D. Westlandicum*—were evidently close allies, *intermedium* so far as the foliage was concerned, *Westlandicum* with respect to the fruit. Under these circumstances I applied to Kew with the object of having these two plants compared with the type specimens, but, unfortunately, it was found that the latter were no longer in the herbarium. About this time Dr. Pilger, of Berlin, took up the study of the *Taxaceae* for "Das Pflanzenreich." Fortunately, he found one of Colenso's original specimens in the Imperial Herbarium at Vienna. He has thus been able to compare it with the other New Zealand species, and has satisfied himself that it is identical with *D. Westlandicum*. I willingly accept this determination, although *D. Westlandicum* usually has much more slender branches than those figured in the original plate. I am also glad to take this opportunity of referring New Zealand students to Dr. Pilger's memoir, which contains carefully prepared descriptions of the whole of the New Zealand Taxads, and much valuable information respecting them.

7. **D. laxifolium** *Hook. f. in Hook. Lond. Journ. Bot.* iv (1845) 143.—A small prostrate shrub with very slender trailing branches 3–24 in. long; rarely suberect, and reaching a height of 2 ft. Leaves of young plants lax, spreading, $\frac{1}{5}$–$\frac{1}{3}$ in. long, narrow-linear, acute, flat, curved; with the growth of the plant gradually becoming shorter, broader and thicker, and more closely set. Leaves of mature plants varying from $\frac{1}{8}$ in. long, linear-oblong, obtuse or subacute, spreading, $\frac{1}{25}$–$\frac{1}{20}$ in. long, broadly ovate or oblong, obtuse, keeled or rounded on the back, closely imbricate. Flowers dioecious or monoecious. Males solitary, terminal, sessile, $\frac{1}{5}$–$\frac{1}{4}$ in. long. Female flowers solitary and terminal. Nut small, erect, oblong, obtuse with a small curved apiculus, about $\frac{1}{8}$ in. long; receptacle sometimes dry, sometimes swollen and succulent.—*Hook. f. Ic. Plant.* (1852) t. 825; *Fl. Nov. Zel.* i (1853) 234; *Handb. N.Z. Fl.* (1864) 269; *T. Kirk in Trans. N.Z. Inst.* x (1878) 388; *Forest Fl.* (1889) t. 87; *Pilger in Pflanzenr.* (1903) 50; *Cheesem. Man. N.Z. Fl.* (1906) 657; *Ill. N.Z. Fl.* (1914) t. 189; *Cockayne Veg. N.Z.* (1921) t. 41.

NORTH ISLAND: Tongariro, *Bidwill, Hector! T. F. C.;* Ruapehu, *Spencer! T. F. C.;* Ruahine Mountains, *Colenso! H. Hill! A. Hamilton! B. C. Aston!* SOUTH ISLAND, STEWART ISLAND: Common in mountain districts throughout. Usually between 2500 and 4000 ft., but descends to sea-level in Stewart Island.

A very remarkable little species, probably the smallest known pine. Fruiting specimens can often be seen barely 3 in. in diameter, although the usual size of the plant is much more. The minute imbricated leaves are often entirely wanting, even in old plants; at other times both imbricated and spreading leaves occur on the same branch.

3. **PHYLLOCLADUS** L. C. Rich. 1826.

Trees or shrubs; branches often whorled; branchlets flattened and expanded into rigid and coriaceous toothed or lobed leaf-like cladodia. True leaves reduced to linear scales. Flowers monoecious or dioecious. Males fascicled at the tips of the branchlets, catkin-like, peduncled; each peduncle arising from the axil of a leafy bract. Staminal column oblong or cylindrical; anthers numerous, densely spirally imbricate, 2-celled; connective prolonged into an acute claw. Female flowers sessile on the margins of the cladodia or on peduncle-like divisions of the cladodia. Ovuliferous scales 1 or several, thick and fleshy, free. Ovule solitary, erect. Seeds erect, ovoid or oblong, compressed, protruding from the enlarged and fleshy scales, each seated within a cup-shaped aril Cotyledons 2.

Besides the 3 species found in New Zealand, there is one in Tasmania, another in Borneo, and a sixth in New Guinea and the Philippine Islands. The genus is remarkable for the flattened cladodes or leaf-like branchlets, which take the place of the true leaves, these last being reduced to linear deciduous scales. The New Zealand species have been excellently described and figured by Mr. Kirk in vol. x of the "Transactions of the New Zealand Institute" and in his "Forest Flora."

* Cladodes pinnately arranged.

Tree 50–70 ft. Cladodes ½–1 in. Female flowers on the margins of the cladodes	1. *P. trichomanoides.*
Tree 25–40 ft. Cladodes 1–2½ in. Female flowers peduncled on the rhachis below the cladodes	2. *P. glaucus.*

** Cladodes simple.

Shrub or tree 5–25 ft. Cladodes ½–1 in. Female flowers on the margins of the cladodes near the base	3. *P. alpinus.*

1. **P. trichomanoides** *D. Don in Lamb. Pin.* ed. ii, App.—A tall graceful tree 50–70 ft. high; trunk 1–3 ft. diam.; branches whorled, slender, spreading. Cladodes or flattened leaf-like branchlets alternate and distichous on whorled rhachises 1–3 in. long, each rhachis and its cladodes resembling a pinnate leaf; each cladode ½–1 in. long, obliquely cuneate or rhomboid, thick and coriaceous, lobed or pinnatifid, the lobes truncate or erose; veins spreading. Leaves of seedling plants ½–¾ in. long, narrow-linear, soon deciduous; of older plants reduced to minute subulate scales at the base of the rhachises of the cladodes or of the cladodes themselves. Flowers monoecious. Males in fascicles of 5–10 at the tips of the branchlets, ⅓–½ in. long. Females on the margins of modified cladodes at the tips of the branchlets, cladodes much reduced in size, often little more than a peduncle, each flower in the axil of a minute subulate bract. Nuts solitary, compressed, half exserted beyond the thickened and fleshy scales; aril cupular, with an irregularly crenulate margin.—*A. Cunn. Precur.* (1836) n. 326; *Raoul Choix* (1846) 41; *Hook. Ic. Plant.*

Hook Ic. Plant. tab. 549–551 Rich.
P. trichomanoides – Rich. Conif. p. 23
d129, K.S.

(1843) t. 549, 550, 551 ; *Hook f. Fl. Nov. Zel.* i (1853) 235 ; *Handb. N.Z. Fl.* (1864) 259 ; *T. Kirk in Trans. N.Z. Inst.* x (1878) 381 ; *Forest Fl.* (1889) t. 6, 7 ; *Pilger in Pflanzenr.* iv, 5 (1903) 97 ; *Cheesem. Man. N.Z. Fl.* (1906) 658 ; *Ill. N.Z. Fl.* ii (1914) 190. P. rhomboidalis *A. Rich. Fl. Nouv. Zel.* (1832) 363 (*not of L. C. Rich.*).

North Island : In forests from the North Cape to Taranaki and Hawke's Bay, not uncommon. South Island : Northern portions of Nelson and Marlborough, advancing along the West Coast as far south as Westport. Sea-level to 2500 ft. *Tanekaha ; Toatoa ; Celery-leaved Pine.*

Wood white, close-grained, free from knots and other defects, very serviceable for sleepers, piles, the timbers of bridges, and probably for general building purposes. Bark often used for tanning, and by the Maoris for the preparation of a red dye.

2. **P. glaucus** *Carr. Trait. Gen. Conif.* (1855) 502.—A small handsome tapering tree 25–40 ft. high ; branches stout, whorled ; trunk 12–18 in. diam., rarely more. Cladodes or flattened leaf-like branchlets alternate and distichous on a rhachis 4–12 in. long, glaucous when young, 1–2½ in. long, rhomboid or obliquely ovate-cuneate, extremely coriaceous, deeply or coarsely toothed or lobed, lobes obtuse or acute. True leaves on seedling plants ½–1 in. long, linear, obtuse, membranous ; on mature plants chiefly developed at the base of the young rhachises and falling away very early. Flowers dioecious or monoecious. Males very numerous, in fascicles of 10–20 at the tips of the branches, ¾–1 in. long, on stout peduncles of equal length. Female flowers forming globose heads terminating short stout distichous peduncles (modified cladodes) springing from the rhachis below the cladodes ; fully ripe heads ½ in. long. Nuts 8–20, compressed, about ⅛ in. long, half exserted beyond the thickened scales ; aril cupular.—*T. Kirk in Trans. N.Z. Inst.* i (1868) 149, *and* x (1878) 380 ; *Forest Fl.* (1889) t. 98, 99 ; *Pilger in Pflanzenr.* iv, 5 (1903) 95 ; *Cheesem. Man. N.Z. Fl.* (1906) 658.

North Island : Mongonui County, *H. Carse !* between Whangape and Hokianga, *T. Kirk !* between Hokianga and the Northern Wairoa, *Petrie !* Puhipuhi Forest, *R. Mair !* Great Barrier Island, Omaha, *T. Kirk !* Waitakerei Ranges and Birkdale (near Auckland), *T. F. C. ;* from Cape Colville to the Thames goldfields and Te Aroha, *T. Kirk ! Adams ! T. F. C. ;* Wairoa South, *T. Kirk !* near Titiraupenga, *T. F. C. ;* Rainbow Mountain (near Waiotapu), *E. Phillips Turner !* Sea-level to 2000 ft. *Toatoa.*

A very distinct species, quite the most handsome of the New Zealand Taxads, and easily recognized by the robust branches, very large cladodes, and large female flowers. Carrière's description, founded on garden specimens of doubtful origin cultivated in France, hardly agrees with wild specimens, but probably refers to the same species.

3. **P. alpinus** *Hook. f. Fl. Nov. Zel.* i (1853) 235, t. 53.—A shrub or small tree, usually from 8–25 ft. high, but in exposed alpine localities often reduced to a bush of 3–6 ft. ; branches numerous, short, stout, spreading ; trunk short, 6–14 in. diam. Cladodes simple, crowded, spreading, ½–1½ in. long, variable in shape, linear-oblong to oblong-rhomboid, obtuse or acute, very coriaceous, glaucous, lobed or pinnatifid, lobes usually obtuse. True leaves on seedling plants linear, ¼–½ in. long. Flowers monoecious. Males in fascicles of 2–5 at the tips of the branchlets, ¼–⅓ in. long ; peduncles short, sometimes almost wanting. Females forming globose heads towards the base of the cladodes or on the margins of modified ones. Fully ripe heads about ¼ in. diam. ; scales fleshy, bright-red. Nuts small, compressed, exserted beyond the scales ; aril cupular, margin irregularly lobulate. — *Handb. N.Z. Fl.* (1864) 260 ; *T. Kirk in*

Trans. N.Z. Inst. x (1878) 382 ; *Forest Fl.* (1889) t. 100 ; *Pilger in Pflanzenr.* iv, 5 (1903) 98 ; *Cheesem. Man. N.Z. Fl.* (1906) 659. P. trichomanoides *var.* alpinus *Parl. in D.C. Prodr.* xvi, 2 (1868) 498.

North and South Islands : In subalpine and mountain forests from Cape Colville and Te Aroha to Foveaux Strait, abundant. Usually from 1500 to 5000 ft., but descends to sea-level in Westland and in the south of Otago. *Mountain Toatoa.*

Very closely allied to the Tasmanian *P. rhomboidalis* L. C. Rich. (*P. aspleniifolius* Hook. f.), principally differing in the position of the female flowers. It is a very important constituent of the subalpine forests of the South Island, particularly at high altitudes.

Family VIII. **TYPHACEAE.**

Marsh or water plants, with creeping rhizomes, solid cylindrical stems, and long linear leaves sheathing at the base. Flowers minute, monoecious, densely crowded in cylindric spikes or spadices, male spadices always uppermost. Perianth either wanting or of minute scales or hairs. Male flowers : Stamens 1–7 ; filaments slender, distinct or connate ; anthers basifixed, erect, linear or oblong. Female flowers : Ovary superior, sessile or stalked, 1- or rarely 2-celled ; styles as many as the cells, linear, persistent ; stigma unilateral, papillose ; ovules solitary. Fruit dry or spongy, indehiscent. Seed solitary, pendulous ; albumen copious, fleshy or farinaceous ; embryo terete, axile.

Consists of the single genus *Typha*, which is distributed over most parts of the world in marshy districts.

1. **TYPHA** Linn. Syst. I. 1755.

Tall reed-like marsh or aquatic herbs. Leaves all radical, long, linear, erect, spongy. Flowers monoecious, densely crowded in a terminal cylindrical spike furnished with a few deciduous spathaceous bracts ; spikes either continuous or separated into two distinct parts by a broad or narrow interval, the upper portion male, the lower female. Male flowers of 1–7 stamens intermixed with capillary membranous scales ; filaments short or long, distinct or connate ; anthers linear-oblong, basifixed, 4-celled, longitudinally dehiscent ; connective produced at the tip. Female flowers with or without a linear-spathulate bracteole at the base. Ovary long-stalked, the stalk furnished with numerous silky hairs, 1-celled, narrowed into a slender style ; stigma unilateral, linguiform or spathulate ; ovule solitary, pendulous. Fruit very minute, fusiform or narrow-ovoid ; pericarp membranous or coriaceous, at length laterally dehiscent. Seed the same shape as the pericarp ; albumen farinaceous ; embryo axile.

Species 10 to 12, spread over most temperate and tropical regions.

1. **T. angustifolia** *Linn. Sp. Plant.* (1753) 971.—Very variable in stature, 3–8 ft. high or more. Leaves as long as the flowering-stems or sometimes exceeding them, rather narrow, $\frac{1}{5}$–$\frac{1}{2}$ in. broad, rarely more, expanded at the base into a broad sheath often more than a foot in length, plano-convex or convex on both sides. Spike variable in length ; male portion usually from 2 to 6 in. long, in some varieties contiguous to the female part, in others separated from it by an interval sometimes as much as 1 in. long, axis of the spike furnished with reddish-brown hairs mixed with the flowers ; female portion 3–8 in. long, $\frac{1}{3}$–$\frac{3}{4}$ in. broad. Female flowers furnished at the base with a linear spathulate bracteole, the hairs on the pedicel of the

ovary shorter than the stigma.—*A. Rich. Fl. Nouv. Zel.* (1832) 99; *A. Cunn. Precur.* (1836) n. 319; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 238; *Handb. N.Z. Fl.* (1864) 276; *Cheesem. Man. N.Z. Fl.* (1906) 743. T. latifolia *Forst. f. Prodr.* (1786) n. 336 (*not of Linn.*); *Hook. f. Handb. N.Z. Fl.* (1864) 772.

Kermadec Islands, North and South Islands: Abundant in marshy places throughout. Sea-level to 2000 ft. *Bulrush; Raupo.* December–March.

Almost cosmopolitan. The Australian and New Zealand forms are placed by Graebner (Das Pflanzenreich, Heft 2) under var. *Brownii* (*T. Brownii* Kunth) and var. *Muelleri* (*T. Muelleri* Rohrb.). The first of these includes the larger and coarser states, with much of the habit of *T. latifolia*, and, like it, with the male and female spikes contiguous. It differs, however, from *T. latifolia* in the female flowers being bracteolate at the base. Var. *Muelleri* is smaller, and usually has the male and female spikes separated by a distinct interval.

The pollen was formerly collected by the Maoris, made into cakes with water, and then baked and eaten; the starchy rhizome was also used for food in times of scarcity. The leaves were employed for constructing the walls of their houses, or whares, and are still used for the same purpose.

Family IX. **PANDANACEAE.**

Trees or shrubs or climbers, frequently with aerial roots. Leaves usually long and narrow, acuminate, sheathing at the base, coriaceous, keeled, margins and keel spinulose-serrate. Flowers dioecious, both sexes densely crowded on simple or branched spadices protected by leafy spathes. Perianth wanting. Male flowers: Stamens numerous; filaments all distinct or connate in clusters; anthers erect, basifixed, 2-celled. Rudimentary ovary present or absent. Female flowers: Staminodia small or wanting. Ovary 1-celled, free or connate with those of adjoining flowers; stigma nearly sessile, papillose; ovules either solitary and basal, or numerous and attached to parietal placentas. Fruit an oblong or globose mass of densely compacted free or connate tough or fleshy drupes. Seeds solitary or many in each drupe; testa striated; albumen hard and fleshy; embryo minute.

A small order of 3 genera and about 220 species; most abundant in the islands of eastern tropical Africa and the Malay Archipelago, extending southwards to Australia, the Pacific islands, and New Zealand; not known in a native state in America. The leaves of most of the species are used for mat-making, thatching, &c., and would probably be useful for the manufacture of paper. The New Zealand genus extends as far north as Malacca.

Seem Bull

1. **FREYCINETIA** Gaud. 1824. 2:1926:92.

Climbing or scrambling shrubs. Stems often very long, branched, rooting. Leaves long, linear, sheathing at the base, keeled, entire or more usually serrulate. Spadices terminal, fascicled, sessile or pedunculate, enclosed within foliaceous bracts with fleshy and often coloured bases. Male flowers numerous, each one consisting of several stamens surrounding a rudimentary ovary; filaments short; anthers oblong. Female flowers of many 1-celled ovaries densely packed on the rhachis of the spadix, cohering at their bases, each ovary surrounded by minute staminodia, apex broad, truncate, c enulate; placentas 2 or more; ovules numerous, in 2 series on each placenta. Fruit an oblong mass of more or less fleshy or almost woody berries. Seeds numerous, fusiform or ellipsoid; testa crustaceous or membranous; albumen copious; embryo basilar.

A genus of over 50 species, scattered through Malaya, the Pacific islands, and Australia, with one species in New Zealand.

1. **F. Banksii** *A. Cunn. Precur.* (1836) n. 320.—A lofty climber, often reaching the tops of tall trees, or scrambling over rocks or prostrate trunks; branches many, stout, rooting. Leaves numerous towards the tips of the branches, 1½–3 ft. long, ½–1 in. broad, linear-elongate, finely acuminate, broadly sheathing at the base, concave, coriaceous, nerved, margins and midrib minutely spinulose-serrate. Spadices fascicled at the tips of the branches, cylindrical, peduncled, 3–6 in. long, dioecious; bracts numerous, leafy, the innermost with white or pale-lilac thick and succulent bases. Filaments rather long, filiform. Ovaries very densely packed, about ⅓ in. long, rather fleshy in fruit. Seeds small, linear-oblong; testa cellular.—*Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 237, t. 54, 55; *Handb. N.Z. Fl.* (1864) 275; *Bot. Mag.* t. 6028; *Cheesem. Man. N.Z. Fl.* (1906) 741.

North Island: Abundant in forests from the North Cape to the East Cape and Taranaki, less plentiful from thence southwards to Wellington. South Island: Lowland districts in Nelson and Marlborough, and along the West Coast from Collingwood to Okarito and Milford Sound, not common. Sea-level to 2500 ft. *Kiekie; Tawhara* (the edible bracts); *Ureure* (the fruit). September–November; ripe fruit in May.

The leaves are occasionally plaited into kits or baskets by the Maoris. The white fleshy bracts surrounding the spadices are sweet and sugary, with an aromatic flavour, and are often eaten; the fruit less commonly so. I have seen no description of *F. inclinans* Benn. Pl. Jav. Rar. i, 32, said to be found in New Zealand. It is not generally known that when growing near a plentiful supply of water *Freycinetia* puts out numerous "floating roots." These are sometimes several feet in length, and are excessively branched, the ultimate divisions being filiform. They are regularly girdled with conspicuous spongy or corky whitish rings, which give the roots a very remarkable appearance. It is hoped that their structure and use will shortly be investigated.

Family X. SPARGANIACEAE.

Marsh or water plants with creeping rhizomes. Stems simple or branched, erect or floating. Leaves usually crowded at the base of the stems, linear, sheathing at the base. Flowers monoecious, crowded in distant globose heads towards the summit of the stem and its branches, the lower heads female, the upper male. Perianth of 3–8 irregular chaffy scales. Male flowers: Stamens 3–4, rarely more; their filaments distinct; anthers oblong, dehiscing longitudinally. Female flowers: Ovary ovoid or oblong, sessile or nearly so, 1–2-celled, produced into 1–2 long or short styles; stigma unilateral; ovule solitary, pendulous. Fruit obovoid, spongy, tipped by the persistent style; endocarp bony. Seed with a membranous testa; albumen farinaceous; embryo axile.

A small family, consisting of the single genus *Sparganium* Linn., which comprises sixteen or eighteen well-defined species. All these are confined to the North Temperate Zone, with the exception of the New Zealand species, which is also found in Australia.

1. SPARGANIUM Linn.

Characters of the family, as above.

1. **S. antipodum** *Graebner in Allg. Bot. Zeitschr.* iv (1899) 33.—Stems slender, erect, 1–2 ft. high. Leaves very long, the lower radical ones usually far surpassing the inflorescence, $\frac{1}{10}$–$\frac{1}{5}$ in. broad, flattish above, acutely and prominently keeled beneath, tip acute, lower portion expanded

S. subglobosum Morong Bull. Torr. Bot. Club. 15:(5) 1888 73–81. t. 1x12.

into a long but rather narrow sheath. Inflorescence simple in small specimens, but usually with 1–3 slender flexuous branches bearing male heads alone or very rarely with a single female below the males; main rhachis with 2–4 distant female heads below, and 3–12 more closely placed male ones above; the lower portion of the inflorescence with long leafy bracts. Filaments of the male flowers long, considerably more than twice the length of the scales. Stigma narrow, elongate. Ripe fruit about $\frac{1}{6}$ in. long, broadly obovoid, mucronate with the short thick persistent style.—*Cheesem. Man. N.Z. Fl.* (1906) 744; *Ill. N.Z. Fl.* ii (1914) t. 205. S. angustifolium *R. Br. Prodr.* (1810) 338 (*not of Michx.*); *Benth. Fl. Austral.* vii (1878) 160; *Col. in Trans. N.Z. Inst.* xvi (1884) 339. S. simplex *Hook. f. Fl. Nov. Zel.* i (1853) 238; *Handb. N.Z. Fl.* (1864) 277 (*not of Huds.*).

North Island: Watery places from the North Cape to Wellington, not uncommon. South Island: Near Picton, *J. Rutland!* swamps at Methven, Canterbury, *Dr. Gaze Maru.* December–March.

Also in Australia, from Queensland to Victoria. *S. subglobosum* Morong in Bull. Torrey Club, xv (1888) 76, t. 79, f. 1, said to have been collected at the Bay of Islands by the American Exploring Expedition, is probably the same, and, if so, Morong's name will take precedence.

see Hutch. 1934: 39 Syn class.

Family XI. NAIADACEAE.

Submerged or floating fresh-water or marine aquatic plants, or marsh herbs. Stems often elongated, slender, branched, jointed; sometimes short and almost wanting. Leaves very various, altogether submerged and translucent, or floating and opaque, or all radical, sheathing at the base; stipules wanting or interpetiolar, connate and sheathing. Flowers small and inconspicuous, usually green, hermaphrodite or unisexual, variously arranged. Perianth either wanting, or of 3–6 inferior segments valvate in bud. Stamens 1–6, hypogynous; anthers basifixed, erect, 1–2-celled. Ovary superior, of 1–6 distinct or more or less connate carpels, each 1-celled with usually a single erect or pendulous ovule; style long or short, stigma various. Fruit of 1–6 indehiscent nutlets or utricles, rarely drupaceous. Seed solitary, testa membranous; albumen wanting; embryo straight or curved, radicle unusually large.

A small family, dispersed over the whole world in marshy places, ponds, lakes, rivers, &c., also including some widely spread marine plants. Genera 16, species estimated at 120. The order cannot be said to have any important properties or uses. With the exception of *Lepilaena*, which is found elsewhere in Australia alone, all the New Zealand genera have a wide range in both temperate and tropical climates. The *Naiadaceae* are now frequently broken up into three or four families, but in a small flora like that of New Zealand it seems undesirable to multiply such divisions.

A. Flowers hermaphrodite. Perianth of 4–6 herbaceous segments.

Marsh plants with linear radical leaves. Flowers on erect scapes. Perianth-segments 6 .. .. 1. Triglochin.

Aquatic plants with submerged or floating stems and leaves. Flowers in axillary or terminal spikes. Perianth-segments 4.. 2. Potamogeton.

B. Flowers unisexual (except in Ruppia). *Perianth wanting or minute and hyaline.*

* Stems and leaves filiform, submerged.

Flowers hermaphrodite, 2 or 3 on a peduncle greatly elongating in fruit. Perianth wanting. Stamens 2; anthers almost sessile.. .. .. 3. Ruppia.

Flowers unisexual, axillary, nearly sessile. Perianth wanting or female small and hyaline. Stamen 1, filament slender .. 4. Zannichellia.

Flowers unisexual, axillary, nearly sessile. Perianth of 3 hyaline scales. Stamens 3; anthers sessile, cohering by their backs into a columnar mass .. .. 5. LEPILAENA.

** Stems creeping in sand or mud in salt water. Leaves ribbon-like, flat, nerved.

Flowers unisexual, enclosed in the membranous sheathing base of a floral leaf .. .. 6. ZOSTERA.

1. **TRIGLOCHIN** Linn.

Perennial marsh herbs. Roots fibrous. Leaves all radical, filiform or rush-like, flat or terete. Scapes slender, naked, erect, bearing a raceme or spike of small green hermaphrodite flowers. Perianth-segments 3 or 6, herbaceous, concave, deciduous. Stamens 6, inserted on the base of the perianth-segments; filaments very short; anthers didymous, extrorse. Carpels 6, distinct or more or less connate; stigmas penicillate; ovules solitary in each carpel, basilar, erect, anatropous. Fruit of 3 or 6 free or connate coriaceous nutlets separating from a central axis. Seeds erect, cylindric or ovoid, terete or compressed; testa membranous; embryo straight.

About 12 species are known, spread through most temperate or subtropical regions, but especially plentiful in Australia. Both the New Zealand species are widely distributed.

Triglochin is often regarded as forming (with 3 other small genera) a distinct order (*Juncaginaceae*), but for the purposes of this work it appears most convenient to merge it with the *Naiadaceae*.

Scape 3–10 in. high. Fruit subglobose .. .. .. 1. *T. striata.*

Scape 6–24 in. high. Fruit clavate .. .. 2. *T. palustre.*

1. **T. striata** *Ruiz and Pav. Fl. Per.* iii, 72; *var.* **filifolium** *Buch. Index Crit.* (1868) 59.—Rhizome short, stoloniferous. Leaves numerous, very narrow-linear or almost filiform, semi-terete, variable in length, shorter or rather longer than the scape. Scape 3–10 in. high; raceme usually occupying about $\frac{1}{2}$ the length. Flowers numerous, shortly pedicelled, minute, about $\frac{1}{12}$ in. diam. Outer perianth-segments broadly ovate; inner smaller and narrower. Perfect stamens 3, at the base of the outer segments; three inner abortive, without pollen, sometimes altogether wanting. Fruit globose, $\frac{1}{10}$ in. diam., of 3 perfect carpels separating from a central axis and leaving 3 scale-like barren ones attached to it.—*Buchenau in Pflanzenr.* iv (1903) 10; *Cheesem. Man. N.Z. Fl.* (1906) 747. T. striata *Benth. Fl. Austral.* vii (1878) 166. T. triandra *Michx. Fl. Bor. Am.* i (1803) 208; *Hook. f. Fl. Nov. Zel.* i (1853) 236; *Handb. N.Z. Fl.* (1864) 278. T. flaccida *A. Cunn. Precur.* (1836) n. 231; *Raoul Choix* (1846) 41. T. filifolium *Sieb. ex Spreng. Syst.* iv (1825) 142; *Hook. Ic. Plant.* (1843) t. 579.

NORTH AND SOUTH ISLANDS, STEWART ISLAND, CHATHAM ISLANDS: Abundant throughout in marshes near the sea; also inland in various localities in the thermal-springs district from Te Aroha and Rotorua to Taupo and Tokaanu. October–January.

The New Zealand variety is also found in Australia, Tasmania, and Chile; the typical state ranges throughout almost the whole of North and South America, and also occurs in South Africa.

2. **T. palustris** *Linn. Sp. Plant.* (1753) 338.—Rhizome short, stoloniferous. Leaves all radical, much shorter than the scape, narrow-linear or filiform, semiterete, upper surface faintly grooved. Scape slender, 6–24 in.

high; raceme elongating after flowering. Flowers numerous, shortly pedicelled, minute, green or greenish-purple. Perianth-segments ovate, all equal. Stamens 6, all fertile; anthers purple. Fruit appressed to the rhachis, linear-clavate, $\frac{1}{4}$ in. long; carpels 3, very slender, almost awned at the base, attached to the axis by the tip.—*Cheesem. in Trans. N.Z. Inst.* xiv (1882) 300; *Man. N.Z. Fl.* (1906) 747.

South Island: Canterbury—Broken River, *J. D. Enys* and *T. F. C.*; Rangitata Valley, *Haast!* Lake Tekapo and Tasman Valley, *T. F. C.* Otago—Ophir, Black's, *Petrie!* 2000–3000 ft. December–January.

A plant with a wide distribution in the Northern Hemisphere, also found in extratropical South America, but not yet detected in Australia.

2. **POTAMOGETON** Linn.

Perennial aquatic herbs. Stems slender, simple or branched. Leaves wholly submerged and translucent, or floating and opaque, alternate or opposite, entire or toothed; stipules intrafoliar, free, or adnate to the petiole or base of the leaf. Flowers small, green, hermaphrodite, ebracteate, sessile in a dense spike on an axillary peduncle arising from a membranous spathe. Perianth-segments 4, small, herbaceous, concave, valvate. Stamens 4, inserted at the base of the segments; anthers sessile, 2-celled, extrorse. Carpels 4, sessile, distinct, 1-celled; stigma oblique, decurrent; ovules solitary, affixed to the inner angle of the cell, campylotropous. Ripe carpels or drupelets 4, small, coriaceous or spongy, ovoid or subglobose, obtuse or beaked by the recurved persistent stigma, 1-seeded. Seed curved, reniform; testa membranous; embryo with a large radicle and narrow incurved cotyledon.

A genus widely spread in the fresh or brackish waters of almost all temperate or subtropical regions, more rare in the tropics. Species variously estimated at from 40 to 100 or more, according to the different views of authors, extremely variable, and most difficult of discrimination. The New Zealand forms have never been carefully sought for, and in all probability other species will be added to those described herein.

A. Floating leaves more or less coriaceous, with a broad long-petioled lamina, different in shape from the membranous submerged ones. Stipules free.

Floating leaves 2–4 in., biplicate at the base. Submerged leaves wanting or reduced to phyllodes. Fruit large, $\frac{1}{6}$ in. long, keeled on the back when dry	1. *P. natans.*
Floating leaves 1–3 in., not plicate at the base. Submerged leaves few, linear-lanceolate. Fruit small, $\frac{1}{12}$–$\frac{1}{10}$ in., rounded on the back	2. *P. polygonifolius.*
Floating leaves $\frac{3}{4}$–$1\frac{3}{4}$ in. Submerged leaves numerous, 2–4 in. Fruit small, $\frac{1}{10}$ in., keeled on the back when dry	3. *P. Cheesemanii.*

B. Leaves all submerged and uniform, sessile, membranous.

Leaves 1–4 in. by $\frac{1}{8}$–$\frac{1}{4}$ in., linear-ligulate, obtuse; stipules free, lacerate. Spike dense	4. *P. ochreatus.*
Leaves 2–4 in. by $\frac{1}{20}$–$\frac{1}{15}$ in., very narrow-linear or filiform; stipules adnate. Spike interrupted	5. *P. pectinatus.*

1. **P. natans** *Linn. Sp. Plant.* (1753) 126.—Stems creeping below, long or short, simple or sparingly branched, terete. Floating leaves on long petioles; lamina 2–4 in. long, oblong or elliptic or elliptic-lanceolate, acute or subacute, subcordate and shortly biplicate at the base, coriaceous, 20–30-nerved with copious cross-veins and minute areolation; stipules very long and conspicuous, 3–5 in., free, acuminate. Submerged leaves

See J. A. Hagstrom in K. B. V. Handbk 13:55, No. 5, 1916. pp. 75, 157, 172, 182.

wanting or if present few and reduced to long and narrow phyllodes without any lamina. Peduncles stout, 2–4 in. long, bearing a dense-flowered spike 1½–2 in. long. Perianth-segments broadly rhomboidal. Fruit ⅙ in. long, turgid, obliquely ovoid, keeled on the back when dry, beak short.—*Hook. f. Fl. Nov. Zel.* i (1853) 236; *Handb. N.Z. Fl.* (1864) 278; *Benth. Fl. Austral.* vii (1878) 170 (*in part*); *A. Bennett in Journ. Bot.* xxv (1887) 177; *Cheesem. Man. N.Z. Fl.* (1906) 748.

North and South Islands: I have seen specimens from both Islands, and have gathered it myself in the Waikato River near Huntly. Mr. Arthur Bennett, whose knowledge of the genus is unrivalled, also informs me that he has seen undoubted specimens from New Zealand. It must, however, be rare; for in an expedition made a few years ago along the whole course of the Lower Waikato I failed to find it, although all the other species known from New Zealand were observed.

2. **P. polygonifolius** *Pourr. in Mem. Acad. Toul.* iii (1788) 325.—Stem creeping at the base, long or short, simple or sparingly branched. Floating leaves on long petioles; lamina 1–3 in. long, elliptic-oblong to lanceolate, acute or obtuse, rounded or subcordate or acute at the base, not plicate, thinly coriaceous; stipules much shorter than in *P. natans*, 1–1½ in. long. Submerged leaves linear-lanceolate, acute. Peduncles variable in length, rather slender; spike dense-flowered, ¾–1½ in. long. Perianth-segments transversely elliptic. Fruit small, reddish, $\frac{1}{12}$–$\frac{1}{10}$ in. long, blunt and rounded on the back, not keeled, beak very short.—*T. Kirk in Trans. N.Z. Inst.* iii (1871) 165; *Cheesem. Man. N.Z. Fl.* (1906) 749.

North and South Islands, Stewart Island: Ponds and small streams from the North Cape southwards, not uncommon. Sea-level to 4500 ft. December–April.

Distinguished from *P. natans* by the smaller and more membranous leaves, much shorter stipules, slender peduncles, and much smaller fruit not keeled on the back when dry. Several of my specimens have been examined by Mr. A. Bennett, who informs me that their identity with *P. polygonifolius* cannot be questioned. The

Althenia tricostata (T. Kirk) Asch.
Tasmanian Pondweed - Potamogeton.
see p 131 of this book.

The most abundant [illegible] numerous submerged leaves and smaller floating ones at once separate it from *P. natans*, to say nothing of other differences. According to Mr. Bennett, it is also found in Tasmania.

high; raceme elongating after flowering. Flowers numerous, shortly pedicelled, minute, green or greenish-purple. Perianth-segments ovate, all equal. Stamens 6, all fertile; anthers purple. Fruit appressed to the rhachis, linear-clavate, $\frac{1}{4}$ in. long; carpels 3, very slender, almost awned at the base, attached to the axis by the tip.—*Cheesem. in Trans. N.Z. Inst.* xiv (1882) 300; *Man. N.Z. Fl.* (1906) 747.

South Island: Canterbury—Broken River, *J. D. Enys* and *T. F. C.*; Rangitata Valley, *Haast!* Lake Tekapo and Tasman Valley, *T. F. C.* Otago—Ophir, Black's, *Petrie!* 2000–3000 ft. December–January.

A plant with a wide distribution in the Northern Hemisphere, also found in extratropical South America, but not yet detected in Australia.

2. **POTAMOGETON** Linn.

Perennial aquatic herbs. Stems slender, simple or branched. Leaves wholly submerged and translucent, or floating and opaque, alternate or opposite, entire or toothed; stipules intrafoliar, free, or adnate to the petiole or base of the leaf. Flowers small, green, hermaphrodite, ebracteate, sessile in a dense spike on an axillary peduncle arising from a membranous spathe. Perianth-segments 4, small, herbaceous, concave, valvate. Stamens 4, inserted at the base of the segments; anthers sessile, 2-celled, extrorse. Carpels 4, sessile, distinct, 1-celled; stigma oblique, decurrent; ovules solitary, affixed to the inner angle of the cell, campylotropous. Ripe carpels or drupelets 4, small, coriaceous or spongy, ovoid or subglobose, obtuse or beaked by the recurved persistent stigma, 1-seeded. Seed curved, reniform; testa membranous; embryo with a large radicle and narrow incurved cotyledon.

A genus widely spread in the fresh or brackish waters of almost all temperate or subtropical regions, more rare in the tropics. Species variously estimated at from 40 to 100 or m
and most difficul
sought for, and

wanting or if present few and reduced to long and narrow phyllodes without any lamina. Peduncles stout, 2–4 in. long, bearing a dense-flowered spike 1½–2 in. long. Perianth-segments broadly rhomboidal. Fruit ⅙ in. long, turgid, obliquely ovoid, keeled on the back when dry, beak short.—*Hook. f. Fl. Nov. Zel.* i (1853) 236; *Handb. N.Z. Fl.* (1864) 278; *Benth. Fl. Austral.* vii (1878) 170 (*in part*); *A. Bennett in Journ. Bot.* xxv (1887) 177; *Cheesem. Man. N.Z. Fl.* (1906) 748.

North and South Islands: I have seen specimens from both Islands, and have gathered it myself in the Waikato River near Huntly. Mr. Arthur Bennett, whose knowledge of the genus is unrivalled, also informs me that he has seen undoubted specimens from New Zealand. It must, however, be rare; for in an expedition made a few years ago along the whole course of the Lower Waikato I failed to find it, although all the other species known from New Zealand were observed.

2. **P. polygonifolius** *Pourr. in Mem. Acad. Toul.* iii (1788) 325.—Stem creeping at the base, long or short, simple or sparingly branched. Floating leaves on long petioles; lamina 1–3 in. long, elliptic-oblong to lanceolate, acute or obtuse, rounded or subcordate or acute at the base, not plicate, thinly coriaceous; stipules much shorter than in *P. natans*, 1–1½ in. long. Submerged leaves linear-lanceolate, acute. Peduncles variable in length, rather slender; spike dense-flowered, ¾–1½ in. long. Perianth-segments transversely elliptic. Fruit small, reddish, $\frac{1}{12}$–$\frac{1}{10}$ in. long, blunt and rounded on the back, not keeled, beak very short.—*T. Kirk in Trans. N.Z. Inst.* iii (1871) 165; *Cheesem. Man. N.Z. Fl.* (1906) 749.

North and South Islands, Stewart Island: Ponds and small streams from the North Cape southwards, not uncommon. Sea-level to 4500 ft. December–April.

Distinguished from *P. natans* by the smaller and more membranous leaves, much shorter stipules, slender peduncles, and much smaller fruit not keeled on the back when dry. Several of my specimens have been examined by Mr. A. Bennett, who informs me that their identity with *P. polygonifolius* cannot be questioned. The species is widely spread in Europe and Asia, and has been recorded from Australia.

3. **P. Cheesemanii** *A. Bennett in Journ. Bot.* xxi (1883) 66.—Stems slender, striated, long or short, simple or branched. Upper leaves alternate or opposite, long-petioled; lamina ¾–1¾ in. long, elliptic-oblong to oblong or lanceolate, obtuse, rounded at the base, coriaceous, 10–16-nerved with numerous cross-veins and minute areolation; stipules broad, subacute. Submerged leaves numerous, usually alternate but sometimes opposite, shortly petioled, 2–4 in. long, ¼–¾ in. broad, oblong-lanceolate to lanceolate or linear, very thin and membranous, translucent, 5–12-nerved with rather distant cross-veins, margins often undulate or crisped, not denticulate. Peduncles variable in length, rather slender; spike dense, ½–¾ in. long. Perianth-segments rhombic-orbicular. Fruit small, about $\frac{1}{10}$ in. long, broadly ovoid, slightly compressed, keeled on the back, beak short.—*A. Bennett l.c.* xxv (1887) 177; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 410; *Man. N.Z. Fl.* (1906) 749; *Ill. N.Z. Fl.* ii (1914) t. 206. P. heterophyllus *Hook. f. Handb. N.Z. Fl.* (1864) 742 (*not of Schreber*). P. natans *var.* australis *T. Kirk ex. A. Bennett in Journ. Bot.* xxv (1887) 177.

North and South Islands, Stewart Island: Abundant throughout in streams, ponds, and lakes. Sea-level to 3000 ft. *Manihi.* November–March.

The most abundant species, universally distributed throughout the Dominion. The numerous submerged leaves and smaller floating ones at once separate it from *P. natans*, to say nothing of other differences. According to Mr. Bennett, it is also found in Tasmania.

Ann Sc. Nat. 2 t. 18 (1836) 117.

4. **P. ochreatus** *Raoul Choix* (1846) 13, t. 7.—Stems slender, striate, branched, long or short according to the depth of the water. Leaves all submerged, alternate or the upper opposite, sessile, 1–4 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, linear-ligulate, obtuse or emarginate at the tip, membranous, 3- or 5-nerved with or without finer parallel veins between, transverse veins few; stipules free, at length conspicuously lacerate. Peduncles stout, erect, usually shorter than the leaves, 1–3 in. long; spike short, oblong, about $\frac{1}{2}$ in. long. Fruit broadly obliquely ovoid, subcompressed, $\frac{1}{10}$ in. long, back rounded, beak short, thick.—*Hook. f. Fl. Nov. Zel.* i (1853) 236, *and* ii (1855) 336; *A. Bennett in Journ. Bot.* xxv (1887) 178; *Cheesem. Man. N.Z. Fl.* (1906) 750; *Ill. N.Z. Fl.* ii (1914) t. 207. P. gramineus *Hook. f. Handb. N.Z. Fl.* (1864) 279 (*not of Linn.*). P. obtusifolius *Benth. Fl. Austral.* vii (1878) 172 (*not of Mert. and Koch*).

North and South Islands: Rivers and lakes from the North Cape to Otago, not uncommon. November–March.

This is a much larger and stouter plant than the northern *P. obtusifolius*, to which it was referred by Bentham. It appears to be plentiful in Australia, ranging from Queensland to Tasmania.

5. **P. pectinatus** *Linn. Sp. Plant.* (1753) 127.—Stems long, filiform, much branched, often forming dense masses. Leaves all submerged, alternate, sheathing at the base, 2–4 in. long by $\frac{1}{20}$–$\frac{1}{15}$ in. broad, very narrow-linear or almost filiform, upper channelled on both surfaces, lower flatter, 1–3-nerved with transverse veinlets; stipules adnate with the sheathing base of the leaf. Peduncles long, slender, filiform, not thickened upwards; spike 1$\frac{1}{2}$–2 in. long, of distant whorls of flowers. Fruit rather large for the size of the plant, about $\frac{1}{8}$ in. long, turgid, obscurely keeled on the back, slightly convex in front, rugose when dry, beak very short.—*Hook. f. Fl. Nov. Zel.* ii (1855) 336; *Handb. N.Z. Fl.* (1864) 279; *Benth. Fl. Austral.* vii (1878) 173; *A. Bennett in Journ. Bot.* xxv (1887) 178; *Cheesem. Man. N.Z. Fl.* (1906) 750.

North Island: Auckland—Waikato River and Lake Whangape, *T. Kirk! T. F. C.;* Lakes Tarawera and Rotomahana, *T. Kirk!* mouth of Rangitikei River, Wellington, *Cockayne.* Hawke's Bay—Tangoia Lagoon, *Colenso, A. Hamilton!* Cape Turnagain, *B. C. Aston!* South Island: Canterbury—Lake Forsyth, *T. Kirk!* Otago—Lake Waihola, and still waters of the Taieri Plain, *Petrie!* December–March.

A very widely distributed plant, found in fresh or brackish waters in most parts of the world. It has a local distribution in New Zealand, and, although abundant in some localities, is absent from wide stretches of apparently suitable stations.

3. **RUPPIA** Linn.

Slender submerged much-branched herbs, usually growing in brackish water. Leaves alternate or opposite, filiform, with broad sheathing bases. Flowers minute, hermaphrodite, 2 or more on a spike, at first enclosed in the membranous leaf-sheath, but after flowering the filiform peduncle elongates greatly, and is either straight or spirally coiled. Perianth wanting. Stamens 2, opposite; filaments very short; anthers 2-celled, the cells distinct, opening outwards. Carpels 4; stigma sessile, peltate; ovule solitary, pendulous from the apex of the cell. Fruiting carpels stipitate, obliquely ovoid, obtuse or beaked. Seed uncinate; testa membranous; embryo with a large thick radicle and small incurved cotyledon.

A genus of either one variable species or of several closely allied ones, common in brackish waters in almost all temperate or subtropical countries.

1. **R. maritima** *Linn. Sp. Plant.* (1753) 127.—Stems slender, filiform, variable in length, 6–24 in., leafy throughout. Leaves 2–5 in. long, filiform, with broad membranous sheathing bases. Flowers 2–6 together, at first completely enclosed in the inflated leaf-sheath; but the spike gradually emerges, and is borne up to the surface of the water by the usually conspicuously spirally coiled peduncle. Ripe carpels $\frac{1}{10}$–$\frac{1}{8}$ in. long, greenish, obliquely ovoid, beaked; each one on a slender stipes sometimes more than 1 in. long.—*Hook. f. Fl. Nov. Zel.* i (1853) 236; *Handb. N.Z. Fl.* (1864) 279; *Benth. Fl. Austral.* vii (1878) 174; *Cheesem. Man. N.Z. Fl.* (1906) 751.

North and South Islands: Abundant throughout in brackish-water ponds and lagoons, not so common in fresh-water lakes and streams. December–April.

All the specimens I have seen have spirally coiled peduncles and rather broad sheaths; but in all probability the variety (or species) *rostellata* will also be found, which has straight or flexuous peduncles and narrow leaf-sheaths.

4. ZANNICHELLIA Linn. 1735.

Slender submerged water-plants; stems filiform, branched. Leaves usually opposite, filiform, sheathing at the base; sheaths stipular. Flowers [illegible] monoecious, a single male and female enclosed in the

Zannichellia palustris L.,

= (Lepilaena preissii, F. Muell.)

T.N.Z.I. vol. 53, p. 363.

bent into a short coil.

An almost cosmopolitan genus of 4 or 5 closely allied species, probably all forms of one.

1. **Z. palustris** *Linn. Sp. Plant.* (1753) 969.—Stems very slender, much branched, leafy throughout, often forming dense masses, 3–14 in. long. Leaves opposite or subwhorled, very slender, $\frac{1}{2}$–3 in. long, filiform, flat. Flowers sessile or very shortly pedicelled. Fruiting carpels 3 or 4, about $\frac{1}{12}$ in. long, stipitate or almost sessile, curved, smooth or very obscurely crenate on the back; styles from $\frac{1}{2}$ to almost as long as the carpels.—*Hook. f. Fl. Nov. Zel.* i (1853) 237; *Handb. N.Z. Fl.* (1864) 280; *T. Kirk in Trans. N.Z. Inst.* xxviii (1896) 498; *Cheesem. Man. N.Z. Fl.* (1906) 752.

North Island: Auckland—Abundant in the Waikato River, from Taupiri downwards, also in Lakes Waikare, Whangape, and Waihi, *T. Kirk! T. F. C.* Hawke's Bay—Tangoia Lagoon, *Colenso!* South Island: Otago—Waikouaiti Lagoon, *Petrie!* December–May.

The Waikato specimens have the carpels sessile or nearly so, and decidedly turgid; in those from Hawke's Bay and Otago they are distinctly stipitate, and with longer styles. Both forms have the back of the carpel smooth or nearly so.

Ann Sc. Nat. 2 t. 18 (1842) 117.

4. **P. ochreatus** *Raoul Choix* (1846) 13, t. 7.—Stems slender, striate, branched, long or short according to the depth of the water. Leaves all submerged, alternate or the upper opposite, sessile, 1–4 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, linear-ligulate, obtuse or emarginate at the tip, membranous, 3- or 5-nerved with or without finer parallel veins between, transverse veins few; stipules free, at length conspicuously lacerate. Peduncles stout, erect, usually shorter than the leaves, 1–3 in. long; spike short, oblong, about $\frac{1}{2}$ in. long. Fruit broadly obliquely ovoid, subcompressed, $\frac{1}{10}$ in. long, back rounded, beak short, thick.—*Hook. f. Fl. Nov. Zel.* i (1853) 236, *and* ii (1855) 336; *A. Bennett in Journ. Bot.* xxv (1887) 178; *Cheesem. Man. N.Z. Fl.* (1906) 750; *Ill. N.Z. Fl.* ii (1914) t. 207. P. gramineus *Hook. f. Handb. N.Z. Fl.* (1864) 279 (*not of Linn.*). P. obtusifolius *Benth. Fl. Austral.* vii (1878) 172 (*not of Mert. and Koch*).

North and South Islands: Rivers and lakes from the North Cape to Otago, not uncommon. November–March.

This is a much larger and stouter plant than the northern *P. obtusifolius*, to which it was referred by Bentham. It appears to be plentiful in Australia, ranging from Queensland to Tasmania.

5. **P. pectinatus** *Linn. Sp. Plant.* (1753) 127.—Stems long, filiform, much branched, often forming dense masses. Fl.* (1864) 279; *Benth. Fl. Austral.* vii (1878) 174; *Cheesem. Man. N.Z. Fl.* (1906) 751.

North and South Islands: Abundant throughout in brackish-water ponds and lagoons, not so common in fresh-water lakes and streams. December–April.

All the specimens I have seen have spirally coiled peduncles and rather broad sheaths; but in all probability the variety (or species) *rostellata* will also be found, which has straight or flexuous peduncles and narrow leaf-sheaths.

4. ZANNICHELLIA Linn. 1735.

Slender submerged water-plants; stems filiform, branched. Leaves usually opposite, filiform, sheathing at the base; sheaths stipular. Flowers minute, axillary, monoecious, a single male and female enclosed in the membranous leaf-sheaths. Male flower: Perianth wanting. Stamen 1; filament short at first, elongating as the flower expands; anther 2–3-celled, linear, basifixed; cells dehiscing laterally, connective produced, apiculate. Female flower: Perianth short, cupular, hyaline. Carpels 2–6, sessile; styles long or short; stigma large, obliquely peltate, crenate; ovule solitary, pendulous, orthotropous. Ripe carpels usually 3 or 4, sessile or stalked, curved, oblong or oblong-reniform, slightly compressed, tubercled or crenate or smooth on the back, beaked by the projecting style. Seed pendulous; testa membranous; embryo cylindric, the cotyledonary end bent into a short coil.

An almost cosmopolitan genus of 4 or 5 closely allied species, probably all forms of one.

1. **Z. palustris** *Linn. Sp. Plant.* (1753) 969.—Stems very slender, much branched, leafy throughout, often forming dense masses, 3–14 in. long. Leaves opposite or subwhorled, very slender, $\frac{1}{2}$–3 in. long, filiform, flat. Flowers sessile or very shortly pedicelled. Fruiting carpels 3 or 4, about $\frac{1}{12}$ in. long, stipitate or almost sessile, curved, smooth or very obscurely crenate on the back; styles from $\frac{1}{2}$ to almost as long as the carpels.—*Hook. f. Fl. Nov. Zel.* i (1853) 237; *Handb. N.Z. Fl.* (1864) 280; *T. Kirk in Trans. N.Z. Inst.* xxviii (1896) 498; *Cheesem. Man. N.Z. Fl.* (1906) 752.

North Island: Auckland—Abundant in the Waikato River, from Taupiri downwards, also in Lakes Waikare, Whangape, and Waihi, *T. Kirk! T. F. C.* Hawke's Bay—Tangoia Lagoon, *Colenso!* South Island: Otago—Waikouaiti Lagoon, *Petrie!* December–May.

The Waikato specimens have the carpels sessile or nearly so, and decidedly turgid; in those from Hawke's Bay and Otago they are distinctly stipitate, and with longer styles. Both forms have the back of the carpel smooth or nearly so.

Althenia preissii (Lehm.) Graeb.

5. **LEPILAENA** J. Drummond. 1855.

Very slender submerged water-plants ; stems filiform, branched. Leaves alternate or the floral ones opposite, filiform, sheathing at the base ; sheaths broad, stipular. Flowers minute, axillary, dioecious or rarely monoecious, solitary within the dilated sheathing bases of a pair of floral leaves. Male flowers shortly pedicelled. Perianth very minute, of 3 hyaline scales. Anthers 2 or 3, united by their backs and forming a solid column resembling a single anther ; each anther 2-celled, dehiscing longitudinally. Female flowers sessile or shortly pedicellate. Perianth of 3 hyaline segments longer or shorter than the carpels. Carpels 3, distinct, sessile or shortly stipitate, narrowed into a short or long style ; stigma oblong or spathulate ; ovule solitary, pendulous. Ripe carpels usually 3, oblong, coriaceous, indehiscent, tipped by the persistent style. Seed oblong ; testa membranous ; embryo with a thick obtuse radicle and tapering involute cotyledonary end.

A small genus of 4 species, 3 of which are Australian, one of them said to extend to New Zealand ; the remaining one is endemic in New Zealand. In Engler's "Naturlichen Pflanzenfamilien" the genus is merged with the Mediterranean *Althenia*.

Leaf-sheaths narrow. Anthers 3, connate into a column. Stigma oblong-clavate .. .. 1. *L. Preissii.*

Leaf-sheaths broad. Anthers 2 (or 1 ?). Stigma very large, flat, deeply fimbriate .. .. 2. *L. bilocularis.*

1. **L. Preissii** *F. Muell. Fragm. Phyt. Austral.* viii, 217.—Stems 6–18 in. long, very slender, filiform, branched, often forming dense masses. Leaves filiform or almost capillary ; sheathing bases very narrow. Flowers dioecious ; males solitary within the leaf-sheaths, shortly pedicelled. Perianth minute, cupular. Anthers 3, sessile within the perianth, connate by their backs into a columnar mass, each one 2-celled, cells dehiscing longitudinally. Female flowers solitary, shortly pedicelled. Perianth of 3 distinct segments, rather longer than the carpels. Carpels 3, narrowed into a rather long style ; stigma oblong-clavate. Ripe carpels cylindrical, sessile or nearly so, about ½ in. long.—*Benth. Fl. Austral.* vii (1878) 180 ; *T. Kirk in Trans. N.Z. Inst.* x (1878) App. 40, *and* xxviii (1896) 499 ; *Cheesem. Man. N.Z. Fl.* (1906) 753. Zannichellia Preissii *Lehm. in Plant. Preiss,* ii (1846–48) 3.

North Island : Auckland—Waikato River, near Churchill, *T. Kirk.*

I have seen no New Zealand specimens of this, but according to Mr. Kirk examples collected by him in the locality quoted above were submitted to the late Baron Mueller and by him identified with the Australian *L. Preissii.* It greatly resembles *Zannichellia palustris,* and in the absence of male flowers may have been mistaken for it.

N.Z. Country Journal 2 (1885) 377.

2. **L. bilocularis** *T. Kirk in Trans. N.Z. Inst.* xxviii (1896) 500.—Stems filiform, much branched, 3–12 in. long. Leaves very narrow-linear or filiform, flat, 1-nerved, obtuse ; base broad, expanded into a membranous sheath. Flowers very minute, solitary, dioecious, concealed in the leaf-sheaths. In the male plant the sheathing bases of the floral leaves are broad and much expanded, and conspicuously 2-lobed at the tip. Flowers very shortly pedicelled. Perianth of 3 most minute hyaline scales. Anthers apparently 2, cohering by their backs and resembling a single anther, each 2-celled, longitudinally dehiscent, connective produced. Floral leaves subtending the female flowers with narrower sheaths ; flowers

sessile or very shortly pedicelled. Perianth-segments 3, oblong, entire or 2-lobed, almost as long as the styles. Carpels 3, sessile; styles slender; stigmas very large and broad, deeply fimbriate or laciniate. Ripe carpels about $\frac{1}{15}$ in. long, slightly oblique, turgid, rounded on the back; style almost as long as the carpel.—*Cheesem. Man. N.Z. Fl.* (1906) 753.

N. Island: Tolaga Bay V.U. Cotor. see Allan Vol 65 Trans. p. 231

South Island: Canterbury—Streams flowing into the Selwyn River; near the outlet of Lake Ellesmere, *T. Kirk!* Otago—Lake Waihola, Waikouaiti, Taieri Plain, *Petrie!*

A very curious little plant. Mr. Kirk describes the anthers as solitary; but in Mr. Petrie's Lake Waihola specimens, which are the only males that I have seen, I make the anthers to be 2, placed back to back, but closely resembling a single 4-celled anther. At the same time it is not easy to satisfy oneself as to the structure of the anther from an examination of dried specimens.

see also Bot. Tidsskrift. 31 (1909) 32.

6. **ZOSTERA** Linn. 1741.

Marine submerged plants. Rhizomes slender, branched, creeping and rooting at the nodes, often matted. Stems short, slender, leafy, compressed. Leaves distichous, alternate, narrow-linear, grass-like, 1–5-nerved, sheathing at the base; sheaths stipuliform, with inflexed margins. Flowers monoecious, the males and females placed alternately upon one face of a narrow spadix enclosed within the dilated membranous base of a leaf. Perianth wanting. Male flowers: Anther solitary, sessile, oblong, cylindric, curved, 1-celled; dehiscence longitudinal; pollen confervoid. Female flowers: Carpel solitary, laterally attached above the middle, narrowed into a short subulate style; stigmas 2, capillary; ovule pendulous from the apex of the cell. Ripe carpel oblong, membranous, bursting irregularly. Seed pendulous; testa membranous, often striated; embryo large, deeply grooved, the linear incurved cotyledonary end sunk in the groove.

Three or four closely allied species are known, found in shallow water on the shores of most temperate regions.

North and South Islands, Stewart Island: Muddy and sandy shores throughout, usually between high- and low-water marks. Widely distributed in temperate seas.

Althenia preissii (Kahm.) Graeb.

5. **LEPILAENA** J. Drummond. 1855.

Very slender submerged water-plants; stems filiform, branched. Leaves alternate or the floral ones opposite, filiform, sheathing at the base; sheaths broad, stipular. Flowers minute, axillary, dioecious or rarely monoecious, solitary within the dilated sheathing bases of a pair of floral leaves. Male flowers shortly pedicelled. Perianth very minute, of 3 hyaline scales. Anthers 2 or 3, united by their backs and forming a solid column resembling a single anther; each anther 2-celled, dehiscing longitudinally. Female flowers sessile or shortly pedicellate. Perianth of 3 hyaline segments longer or shorter than the carpels. Carpels 3, distinct, sessile or shortly stipitate, narrowed into a short or long style; stigma oblong or spathulate; ovule solitary, pendulous. Ripe carpels usually 3, oblong, coriaceous, indehiscent, tipped by the persistent style. Seed oblong; testa membranous; embryo with a thick obtuse radicle and tapering involute cotyledonary end.

A small genus of 4 species, 3 of which are Australian, one of them said to extend to New Zealand; the remaining one is endemic in New Zealand. In Engler's "Naturlichen Pflanzenfamilien" the genus is merged with the Mediterranean *Althenia*.

Leaf-sheaths narrow. Anthers 3, connate into a column. Stigma oblong-clavate	1. *L. Preissii.*
Leaf-sheaths broad. Anthers 2 (or 1 ?). Stigma very large, flat, deeply fimbriate	2. *L. bilocularis.*

1. **L. Preissii** *F. Muell. Fragm. Phyt. Austral.* viii, 217.—Stems 6–18 in. long, very slender, filiform, branched, often forming dense masses. Leaves filiform or almost capillary; sheathing bases very narrow. Flowers dioecious; males solitary within the leaf-sheaths, shortly pedicelled. Perianth minute, cupular. Anthers 3, sessile within the perianth, connate by their backs into a columnar mass, each one 2-celled, cells dehiscing longitudinally. Female flowers solitary, shortly pedicelled. Perianth of 3 distinct segments [illegible] Carpels 3, narrowed into a rather long [illegible] nearly [illegible] *in Tr[illegible] Man.*, ii (184[illegible]

N[illegible]

I [illegible] collecte[illegible] Muelle[illegible] *Zannic[illegible]* for it.

2. Stems [illegible] or filiform, [illegible] branous sheath. Flowers very minute, solitary, dioecious, concealed in the leaf-sheaths. In the male plant the sheathing bases of the floral leaves are broad and much expanded, and conspicuously 2-lobed at the tip. Flowers very shortly pedicelled. Perianth of 3 most minute hyaline scales. Anthers apparently 2, cohering by their backs and resembling a single anther, each 2-celled, longitudinally dehiscent, connective produced. Floral leaves subtending the female flowers with narrower sheaths; flowers

sessile or very shortly pedicelled. Perianth-segments 3, oblong, entire or 2-lobed, almost as long as the styles. Carpels 3, sessile; styles slender; stigmas very large and broad, deeply fimbriate or laciniate. Ripe carpels about $\frac{1}{15}$ in. long, slightly oblique, turgid, rounded on the back; style almost as long as the carpel.—*Cheesem. Man. N.Z. Fl.* (1906) 753.

South Island: Canterbury—Streams flowing into the Selwyn River; near the outlet of Lake Ellesmere, *T. Kirk!* Otago—Lake Waihola, Waikouaiti, Taieri Plain, *Petrie!*

A very curious little plant. Mr. Kirk describes the anthers as solitary; but in Mr. Petrie's Lake Waihola specimens, which are the only males that I have seen, I make the anthers to be 2, placed back to back, but closely resembling a single 4-celled anther. At the same time it is not easy to satisfy oneself as to the structure of the anther from an examination of dried specimens.

6. ZOSTERA Linn.

Marine submerged plants. Rhizomes slender, branched, creeping and rooting at the nodes, often matted. Stems short, slender, leafy, compressed. Leaves distichous, alternate, narrow-linear, grass-like, 1–5-nerved, sheathing at the base; sheaths stipuliform, with inflexed margins. Flowers monoecious, the males and females placed alternately upon one face of a narrow spadix enclosed within the dilated membranous base of a leaf. Perianth wanting. Male flowers: Anther solitary, sessile, oblong, cylindric, curved, 1-celled; dehiscence longitudinal; pollen confervoid. Female flowers: Carpel solitary, laterally attached above the middle, narrowed into a short subulate style; stigmas 2, capillary; ovule pendulous from the apex of the cell. Ripe carpel oblong, membranous, bursting irregularly. Seed pendulous; testa membranous, often striated; embryo large, deeply grooved, the linear incurved cotyledonary end sunk in the groove.

Three or four closely allied species are known, found in shallow water on the shores of most temperate regions.

Leaves 3–9 in. × $\frac{1}{16}$–$\frac{1}{10}$ in., truncate or notched at the tip. Spadix with transverse appendages, one folded over each carpel .. 1. *Z. nana.*

Leaves 9–18 in. × $\frac{1}{10}$ in.–$\frac{1}{6}$ in., rounded at the tip .. .. 2. *Z. tasmanica.*

1. **Z. nana** *Roth Enum. Pl. Phaen. Germ.* i (1827) 8. — Rhizomes slender, matted. Leaves 3–9 in. long, rarely more, $\frac{1}{16}$–$\frac{1}{10}$ in. broad, narrow-linear, truncate or obscurely notched at the tip, with 3–5 faint parallel nerves on each side of the stout midrib and distant transverse veinlets, margins thickened. Floral sheaths or spathes $\frac{1}{2}$–1 in. long, on peduncles of equal length, the blade of the leaf continued above the sheath, the sheath itself much wider than the blade. Spadix 6–12-flowered, its margins with transverse membranous appendages folded inwards, one over each carpel. Stigmas usually protruding through the slit of the spathe. Fruit about $\frac{1}{10}$ in. long, oblong, obscurely striate.—*Benth. Fl. Austral.* vii (1878) 176; *T. Kirk in Trans. N.Z. Inst.* x (1878) 392; *Cheesem. Man. N.Z. Fl.* (1906) 754. Z. Muelleri *Irmisch ex Aschers. in Linnaea,* xxxv (1867–68) 168.

North and South Islands, Stewart Island: Muddy and sandy shores throughout, usually between high- and low-water marks. Widely distributed in temperate seas.

2. **Z. tasmanica** *Martens ex Aschers. in Linnaea,* xxxv (1867–68) 168 (?).—Rhizomes slender, wide-creeping. Leaves 9–18 in. long, $\frac{1}{10}$–$\frac{1}{6}$ in. broad, narrow-linear, rounded at the tip, not truncate, with 1–3 stout nerves on each side of the midrib and several finer ones between, cross-veinlets distant. Flowers and fruit not seen.—*Cheesem. Man. N.Z. Fl.* (1906) 754. Z. marina *Hook. f. Handb. N.Z. Fl.* (1864) 742 (*not of Linn.*).

North and South Islands: Not uncommon in sandy or muddy places along the coasts, often in water of considerable depth.

The exact position of the New Zealand plant must remain doubtful until the fructification has been obtained, but it is probably the same as the Australian and Tasmanian *Z. tasmanica*, which seems hardly different from narrow-leaved forms of the northern *Z. marina.*

See Hubbard in Hutch. 1934.

Family XII. **GRAMINEAE.**

Annual or perennial, erect or creeping herbs, rarely (bamboos) shrubby or arborescent. Stem (*culm*) branched at the base, cylindrical or slightly compressed, jointed, generally hollow between the joints; joints (*nodes*) solid, swollen. Leaves alternate, distichous, usually long and narrow, entire, parallel-veined; sheath long, split to the base on one side, at its junction with the blade usually furnished with an erect membranous appendage called the *ligule*. Flowers hermaphrodite or unisexual, minute, solitary in the axils of small bracts (*glumes*) which are imbricated in 2 opposite rows, forming little spikes or *spikelets*. Spikelets usually many, arranged in spikes, panicles, or fascicles. Glumes placed alternately on each side of the axis (*rhachilla*) of the spikelet, the first or lowest 1–6 (commonly the first 2) empty and known as *empty glumes* or *outer glumes*, or simply as glumes. The succeeding 1 or several are called *flowering glumes*, each of them having in its axil a very short branchlet bearing on its upper side a 2-nerved bractlet called the *palea;* the branchlet ending in a flower, which is thus enclosed by the flowering glume and palea. Occasionally 1 or more glumes at the top of the spikelet are empty or enclose rudimentary flowers only. Perianth wanting, unless represented by 2 (rarely 3) minute scales (*lodicules*). Stamens usually 3, rarely 1, 2, or 6, hypogynous; filaments capillary; anthers pendulous, versatile, fugacious. Ovary 1-celled; styles 2 or rarely 3, free or connate at the base, feathery with simple or branched stigmatic hairs; ovule solitary, erect, anatropous. Fruit a seed-like utricle or grain (*caryopsis*) either free within the flowering glume and palea, or adhering to one or both. Seed erect, usually adherent to the membranous pericarp, rarely separable (*Sporobolus*); albumen copious, farinaceous; embryo very small, roundish, on one side of the base of the albumen.

One of the largest of the families of plants, found in all climates and situations, but most numerous in temperate regions. Genera about 325; species probably not less than 3500. In usefulness to man it is exceeded by no other family. The nutritious herbage forms the chief pasturage of our flocks and herds; the cereal grains, as wheat, barley, rye, oats, rice, millet, maize, &c., constitute a very large proportion of our food; sugar is obtained from the sugar-cane and sorghum; while few plants are applied to a greater variety of uses than the various kinds of bamboos. Many species are cultivated for ornamental purposes, from the dwarf varieties used for edgings and lawns to the pampas-grass and giant-bamboo. Of the 33 indigenous genera, one only (*Simplicia*) is endemic; 4 (*Microlaena, Echinopogon, Dichelachne,* and *Amphibromus*) are found elsewhere in Australia and Tasmania alone; and 2 others (*Ehrharta* and

Armstrong J.B. a short history of grasses
N.Z. Country Journal.
Vol 4 (1880) 64–343
5 (1881) 54–65 & 124–126,

Asperella) have a very restricted range, but are not indigenous in Australia. The remaining 26 are widely distributed in either temperate or tropical regions or in both, and some are cosmopolitan. In addition to the indigenous species, a large number of grasses have become naturalized, and every year adds to the list. Most of these are natives of the Northern Hemisphere, and many have been purposely introduced and widely spread through the country on account of their value for pasturage or fodder. The remainder are either weeds of cultivation or inhabitants of waste-places or roadsides, a large proportion having followed the footsteps of civilized man all round the world. A few Australian and subtropical species have also established themselves, but the number of these is not nearly so large as might have been anticipated. Many of the naturalized species have so completely amalgamated with the indigenous flora as to present all the appearance of true natives, and will certainly be taken as such by a beginner unacquainted with their history. It will therefore be advisable, when determining any species, to make frequent reference to the list of naturalized species given in another part of this work, and to become acquainted with their distinguishing characters, which, in the majority of cases, can be learned from any British Flora.

In preparing the first edition of this work I was greatly indebted to Professor E. Hackel, of Graz, Austria, so well known for his wide acquaintance with the family, for undertaking a critical examination of the whole of the New Zealand species then known, and for furnishing me with very full and complete notes, with permission to use the same. In the arrangement then given I largely followed his recommendations, and I find little reason to depart from them when once more revising the family.

Division A. PANICACAE.

Spikelets articulated on their pedicels below the glumes and falling away at maturity; usually 2-flowered, the upper flower perfect and producing seed, the lower flower always male; rhachilla not continued beyond the upper flower.

Tribe I. ANDROPOGONEAE.

Spikelets usually 1-flowered, generally in pairs, rarely in threes or solitary, on the rhachis of a spike or branches of a panicle, all hermaphrodite or some of them male, in the latter case so placed that a male spikelet stands by the side of a hermaphrodite one. Flowering glumes hyaline, often awned, usually much smaller than the empty ones.

Panicle long, dense, cylindrical. Spikelets awnless, almost concealed by long silky hairs .. .. 1. Imperata.

Tribe II. ZOYSIEAE.

Spikelets usually 1-flowered, solitary or in clusters on the rhachis of a spike or raceme. Flowering glumes membranous, never awned, usually smaller than the outer glumes.

Small creeping usually maritime grass. Leaves short, rigid. Spike short, stiff. Spikelets appressed to the rhachis .. .. 2. Zoysia.

Tribe III. PANICEAE.

Spikelets with 1 terminal hermaphrodite flower with or without a male one below it. Flowering glumes awnless, cartilaginous or coriaceous, in fruit hardened and enclosing the grain. Outer glumes thinner in texture than the flowering glumes, rarely awned.

Spikelets 1-flowered, plano-convex, sessile in 2 or 4 rows in one-sided spikes which are either in pairs or form the branches of a simple panicle. Empty glumes 2 .. .. 3. Paspalum.

Spikelets with 2 hermaphrodite flowers, panicled; outer glumes 2, persistent after the rest of the spikelet has fallen away .. 4. Isachne.

Spikelets with 1 hermaphrodite flower and sometimes a male flower below; outer glumes 2 or 3, not awned, the lowest often very small .. .. 5. PANICUM.
Stems weak, decumbent; leaves broad, ovate to lanceolate. Spikelets as in *Panicum*, but outer glumes awned .. .. 6. OPLISMENUS.
Spikelets enclosed, each one or 2-3 together, in an involucre of rigid spines or bristles, often connate into a cup below .. 7. CENCHRUS.
Stout wide-creeping sand-plant. Inflorescence dioecious; males in spikes clustered in heads; females in dense globular heads with long radiating pungent-pointed bracts .. .. 8. SPINIFEX.

DIVISION B. POACEAE.

Spikelets not articulated on the pedicel below the glumes, the rhachilla continuous with the pedicel, and the articulations above the outer glumes and frequently also between the flowering glumes. Flowers 1 to many, the lowest flower perfect, the uppermost often male or imperfect. (Lower flower imperfect in *Phalarideae*.)

TRIBE IV. PHALARIDEAE.

Spikelets with 1 terminal hermaphrodite flower, with or without 1 or 2 male or rudimentary flowers below. Outer glumes 4, the lower 2 sometimes small, the 2 inner sometimes serving as flowering glumes for male flowers.

First and second outer glumes smaller than the third and fourth. Flowering glumes obtuse .. .. 9. EHRHARTA.
First and second outer glumes minute, many times smaller than the third and fourth. Flowering glumes acute .. .. 10. MICROLAENA.
First and second outer glumes as large as the third and fourth, both of which usually contain a male flower .. .. 11. HIEROCHLOE.

TRIBE V. AGROSTIDEAE.

Spikelets 1-flowered; rhachilla frequently produced beyond the flower. Outer glumes 2, usually as long or longer than the flowering glume.

Spikelets panicled. Outer glumes usually longer than the flowering, which are rigid and convolute and awned. Awn long, terminal, bent, usually twisted below the bend .. .. 12. STIPA.
Panicle short and dense, cylindrical, bristly from the long awns. Flowering glume hyaline, 3-fid, middle lobe produced into a long awn. Rhachilla evidently produced .. .. .. 13. ECHINOPOGON.
Panicle dense, cylindrical. Outer glumes compressed, fringed on the keel. Flowering glume hyaline, with a short dorsal awn. Rhachilla not produced .. .. 14. ALOPECURUS.
Panicle long, narrow and spike-like in the New Zealand species. Spikelets small, awnless. Flowering glume usually exceeding the outer glumes. Seed loose in the pericarp and finally expelled from it .. .. 15. SPOROBOLUS.
Spikelets panicled. Outer glumes very minute. Flowering glume awnless, acuminate, pubescent. Palea almost as long as the glume .. .. 16. SIMPLICIA.
Spikelets small, panicled. Flowering glume hyaline, much smaller than the outer glumes, awned on the back or awnless. Palea usually short, often minute or wanting. Rhachilla not produced 17. AGROSTIS.
Spikelets small, panicled. Flowering glume hyaline, smaller than the outer glumes or almost equalling them, awned on the back. Palea more than half as long as the flowering glume. Rhachilla produced beyond the palea, silky .. .. 18. DEYEUXIA.
Panicle long, narrow, dense, bristly from the long awns. Flowering glume hardly shorter than the outer glumes, with a long and fine awn from the back near the tip .. .. .. 19. DICHELACHNE.

Tribe VI. AVENAE.

Spikelets 2- or several-flowered, usually panicled. Flowering glumes generally shorter than the outer glumes, usually awned; awn geniculate and often twisted, rarely straight.

* Awn of the flowering glumes dorsal, rising from below the terminal teeth of the glume, not from between them.

Spikelets 2-flowered. Flowering glumes erose or 2-toothed at the tip, shortly awned .. .. 20. Deschampsia.
Spikelets 2–6-flowered. Flowering glumes sharply 2-toothed at the tip; teeth sometimes almost awned; awn from the back just below the teeth .. .. 21. Trisetum.
Spikelets 5–10-flowered. Flowering glumes rounded at the back; awn dorsal, straight or bent .. .. 22. Amphibromus.

** Awn of the flowering glumes rising from between the terminal lobes or teeth of the glume.

Spikelets several-flowered. Flowering glumes rounded at the back, often ciliate or hairy; awn rigid, often twisted or flattened at the base .. .. 23. Danthonia.

Tribe VII. CHLORIDEAE.

Spikelets 1-many-flowered, crowded in two rows on one side of a flat rhachis or spike; spikes in racemes or digitate.

Spikes digitate or scattered at the top of the culm. Spikelets compressed, several-flowered, awnless. Outer glumes persistent; flowering glumes deciduous .. .. 24. Eleusine.

Tribe VIII. FESTUCEAE.

Spikelets 2-many-flowered, usually panicled or racemed. Flowering glumes generally exceeding the outer glumes, awnless or with 1 or several straight awns, which are usually terminal, rarely dorsal. Rhachilla produced beyond the uppermost flower.

Tall reed-like grasses with silvery panicles. Flowering glumes covered with long hairs, membranous. Rhachilla long, glabrous 25. Arundo.
Spikelets 3–5-flowered, usually rounded on the back. Flowering glumes 2–3-toothed, middle tooth often mucroniform or slightly awned .. .. 26. Triodia.
Panicle spiciform. Spikelets 2–5-flowered, shining, compressed. Flowering glumes scarious, mucronate or shortly awned .. 27. Koeleria.
Spikelets 2-many-flowered, compressed. Flowering glumes keeled at the back, acute or obtuse, awnless, often (together with the rhachilla) clothed at the base with tangled hairs. Hilum punctiform .. .. 28. Poa.
Spikelets 3-many-flowered. Flowering glumes rounded at the back, obtuse, awnless, 5–9-nerved. Lodicules distinct. Hilum punctiform .. .. 29. Atropis.
Spikelets 2-many-flowered. Flowering glumes rounded on the back, more rigid than in *Poa*, acute or awned. Ovary naked or hairy. Hilum long, linear .. .. 30. Festuca.
Spikelets 3-many-flowered. Flowering glumes rounded on the back or slightly keeled, mucronate or awned, 5–9-nerved. Ovary villous at the top .. .. 31. Bromus.

Tribe IX. HORDEAE.

Spikelets 1-many-flowered, sessile in alternate notches on opposite sides of the rhachis of a simple spike, either solitary or several together. Glumes awned or not.

Spikelets solitary in the notches of the rhachis, 2-many-flowered, placed flatwise on the rhachis. Outer glumes conspicuous .. 32. Agropyrum.
Spikelets solitary (or in non-New-Zealand species in pairs) at the notches of the rhachis, 2–4-flowered, placed flatwise on the rhachis. Empty glumes either wanting or reduced to 2 small bristles .. .. 33. Asperella.

1. **IMPERATA** Cyr.

Tall erect perennial grasses. Leaves long. Panicles long, terminal, densely spiciform or narrow-thyrsiform, silky-silvery. Spikelets all similar, numerous, densely clothed with long silky hairs, usually arranged in pairs on the continuous branches of the panicle, one sessile or almost so, the other distinctly stalked, all 1-flowered. Empty glumes 3, subequal, narrow, membranous, awnless, 3–9-nerved, the 2 outer clothed with long hairs. Flowering glume usually much smaller, hyaline. Palea small, broad, hyaline, nerveless. Lodicules wanting. Stamens 1 or 2. Stigma long, exserted from the tip of the spikelet. Grain oblong, with an embryo half its length or more.

A genus of about 6 species, found in the tropical or warm temperate regions of both hemispheres. One of the New Zealand species is very widely diffused, the other is endemic in the Kermadec Islands.

Panicle densely spiciform, cylindric, obtuse, shining. Stamens 2.. 1. *I. arundinacea.*

Panicle not so dense, narrow-lanceolate, acuminate, not shining.
Stamen 1 .. .. 2. *I. Cheesemanii.*

I. cylindrica (L.) Beauv. - var K. (Benth.) Druce 1916 P. 128.

1. **I. arundinacea** *Cyr. Pl. Rar. Ic.* ii (1792) 26, t. 11; var. **Koenigii** *Benth. Fl. Hongk.* 419.—Culms 1–3 ft. high, slender, erect, glabrous, 3–4-noded. Leaves erect, narrow, often exceeding the culms; sheaths rather loose, with a dense erect tuft of hairs at the nodes; ligules short, membranous, truncate; laminae linear from a very narrow base, acuminate, rather rigid, flat or convolute; margins scabrid; midrib stout. Panicle densely spiciform, 3–6 in. long, cylindric, obtuse, silvery-white and shining from the long and silky hairs which conceal the glumes; branchlets very numerous, appressed; pedicels capillary or setaceous, clavate at the apex. Spikelets about $\frac{1}{6}$ in. long, completely enveloped by fine silky hairs $\frac{1}{3}$ in. long. Empty glumes ovate-lanceolate, obtuse or subacute, hyaline, 5–7-nerved or the uppermost nerveless. Flowering glume $\frac{1}{3}$–$\frac{1}{2}$ as long as the upper empty glume, ovate, acute, glabrous, hyaline, nerveless. Palea about $\frac{1}{2}$ as long as the glume, quadrate, truncate, nerveless. Stamens 2. Stigmas long, purple.—*Hack. in D.C. Monog. Phan.* vi, 94; *Stapf. in Fl. Capen.* vii (1898) 321.

North Island: Auckland—Near Kaitaia, *R. H. Matthews!*

Perhaps introduced only, but it is one of those species which might be expected to be indigenous in the extreme north of the Dominion, and I have consequently given it the benefit of the doubt. The species, in some of its forms, is found in all warm countries; var. *Koenigii* is common throughout Africa, and in Australia and Tasmania, stretching northwards to India, China, and Japan.

2. **I. Cheesemanii** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 378.—Perennial, innovation-shoots extravaginal. Culms 1–3 ft. high, simple, stout, erect, glabrous, 3-noded. Leaves numerous, rather shorter than the culms; sheaths loose, bearded at the mouth but otherwise glabrous, the uppermost sheathing the base of the panicle, the lowest scale-like; ligules short, truncate, membranous; laminae linear from a narrow base, acute or acuminate, $\frac{1}{2}$–$\frac{3}{4}$ in. broad, flat, nerved, glabrous; margins scabrid above. Panicle narrow-lanceolate, gradually narrowed upwards into an acute point, 5–10 in. long, $\frac{3}{4}$–$1\frac{1}{4}$ in. broad, dense but not so much so as in *I. arundinacea*, greyish-white with long soft hairs that conceal the glumes, not shining; branches numerous, erecto-patent, flexuose, simple or with short branchlets in the lower half, pedicels clavate above. Spikelets about

$\frac{1}{8}$ in. long, enveloped by long soft hairs $\frac{1}{4}$–$\frac{1}{3}$ in. long. Outer glume as long as the spikelet, lanceolate, subacute, membranous, obscurely 5-nerved, laxly pilose along the back, ciliolate at the apex; the 2nd similar but 3-nerved; 3rd $\frac{1}{3}$ shorter, broadly ovate, obtuse, hyaline, nerveless. Flowering glume $\frac{1}{3}$ shorter than the outer empty glumes, ovate, acuminate, tridentate, hyaline, nerveless. Palea broad, truncate, fimbriate-ciliate. Stamen 1. Stigmas long, purple.—I. arundinacea *Cheesem. in Trans. N.Z. Inst.* xx (1888) 175 (*not of Cyr.*); *Man. N.Z. Fl.* (1906) 843; *Ill. N.Z. Fl.* ii (1914) t. 218.

KERMADEC ISLANDS: Cliffs on the north side of Sunday Island, abundant. *T. F. C., Miss Shakespear! W. R. B. Oliver!*

Closely allied to *I. exaltata* Brong., but a much smaller plant, with a smaller and less branched panicle, larger and broader spikelets on more clavate pedicels, and with the outer glume 5-nerved.

2. **ZOYSIA** Willd.

Small perennial creeping grasses. Culms branched at the base, rigid, erect. Leaves distichous, subulate, often pungent-pointed. Spikelets few, ovoid, 1-flowered, sessile or shortly pedicelled, not distichous, jointed on and closely appressed along a rigid notched unjointed rhachis, forming a short spike. Glumes 2, [illegible]

[illegible] rhizome long, creeping, branched, rigid and wiry. Culms numerous from the rhizome, often branched at the base, erect, rigid, glabrous, usually from 1 to 3 in. high, but sometimes taller and attaining 4–6 in. or even more. Leaves more or less spreading, subulate, flat or convolute, coriaceous; sheaths short, grooved, tipped with a few cilia; ligule wanting. Spike terminal, $\frac{1}{8}$–$\frac{3}{4}$ in. long; spikelets usually 3–5, but in small specimens often reduced to one, and in large ones sometimes as many as 7–9. Outer glume smooth and shining, convolute, coriaceous, tip often produced into a short awn. Flowering glume thin and hyaline, included within the outer glume.—*Hook. f. Fl. Nov. Zel.* i (1853) 312; *Handb. N.Z. Fl.* (1864) 324; *Benth. Fl. Austral.* vii (1878) 506; *Buch. N.Z. Grasses* (1879) t. 13A; *Cheesem. Man. N.Z. Fl.* (1906) 844. Rottboella uniflora *A. Cunn. Precur.* (1836) n. 267; *Raoul Choix* (1846) 39.

NORTH AND SOUTH ISLANDS: Abundant on sandy shores from the North Cape to Banks Peninsula and Okarito, less common in dry places inland, ascending to 2000 ft. at Lake Taupo and in Canterbury and Otago. Also not uncommon on the shores of Australia and Tasmania, extending northwards to India, Malacca, and China.

3. **PASPALUM** Linn.

Annual or perennial grasses, of various habit. Spikelets 1-flowered, orbicular or oblong, obtuse or rarely acute, not awned, sessile or very shortly pedicelled, arranged in one or two rows on one side of a slender

1. **IMPERATA** Cyr.

Tall erect perennial grasses. Leaves long. Panicles long, terminal, densely spiciform or narrow-thyrsiform, silky-silvery. Spikelets all similar, numerous, densely clothed with long silky hairs, usually arranged in pairs on the continuous branches of the panicle, one sessile or almost so, the other distinctly stalked, all 1-flowered. Empty glumes 3, subequal, narrow, membranous, awnless, 3–9-nerved, the 2 outer clothed with long hairs. Flowering glume usually much smaller, hyaline. Palea small, broad, hyaline, nerveless. Lodicules wanting. Stamens 1 or 2. Stigma long, exserted from the tip of the spikelet. Grain oblong, with an embryo half its length or more.

A genus of about 6 species, found in the tropical or warm temperate regions of both hemispheres. One of the New Zealand species is very widely diffused, the other is endemic in the Kermadec Islands.

Panicle densely spiciform, cylindric, obtuse, shining. Stamens 2.. 1. *I. arundinacea.*

Panicle not so dense, narrow-lanceolate, acuminate, not shining.
Stamen 1 .. .. 2. *I. Cheesemanii.*

I. cylindrica (L.) Beauv. - Var K. (Benth.) Druce 1916 P. 128

1. **I. arundinacea** *Cyr. Pl. Rar. Ic.* ii (1792) 26, t. 11; var. **Koenigii** [illegible] slender, erect, glabrous, 3–4-

Imperata arundinacea, var. Koenigii, Benth.
not native to N.Z. see T.N.Z.I.
vol. 57, p. 65. (Ckn. & Allan).

or the uppermost nerveless. Flowering glume [illegible] as long as the [illegible] empty glume, ovate, acute, glabrous, hyaline, nerveless. Palea about $\frac{1}{2}$ as long as the glume, quadrate, truncate, nerveless. Stamens 2. Stigmas long, purple.—*Hack. in D.C. Monog. Phan.* vi, 94; *Stapf. in Fl. Capen.* vii (1898) 321.

North Island: Auckland—Near Kaitaia, *R. H. Matthews!*

Perhaps introduced only, but it is one of those species which might be expected to be indigenous in the extreme north of the Dominion, and I have consequently given it the benefit of the doubt. The species, in some of its forms, is found in all warm countries; var. *Koenigii* is common throughout Africa, and in Australia and Tasmania, stretching northwards to India, China, and Japan.

2. **I. Cheesemanii** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 378.—Perennial, innovation-shoots extravaginal. Culms 1–3 ft. high, simple, stout, erect, glabrous, 3-noded. Leaves numerous, rather shorter than the culms; sheaths loose, bearded at the mouth but otherwise glabrous, the uppermost sheathing the base of the panicle, the lowest scale-like; ligules short, truncate, membranous; laminae linear from a narrow base, acute or acuminate, $\frac{1}{2}$–$\frac{3}{4}$ in. broad, flat, nerved, glabrous; margins scabrid above. Panicle narrow-lanceolate, gradually narrowed upwards into an acute point, 5–10 in. long, $\frac{3}{4}$–$1\frac{1}{4}$ in. broad, dense but not so much so as in *I. arundinacea*, greyish-white with long soft hairs that conceal the glumes, not shining; branches numerous, erecto-patent, flexuose, simple or with short branchlets in the lower half, pedicels clavate above. Spikelets about

$\frac{1}{8}$ in. long, enveloped by long soft hairs $\frac{1}{4}$–$\frac{1}{3}$ in. long. Outer glume as long as the spikelet, lanceolate, subacute, membranous, obscurely 5-nerved, laxly pilose along the back, ciliolate at the apex; the 2nd similar but 3-nerved; 3rd $\frac{1}{3}$ shorter, broadly ovate, obtuse, hyaline, nerveless. Flowering glume $\frac{1}{3}$ shorter than the outer empty glumes, ovate, acuminate, tridentate, hyaline, nerveless. Palea broad, truncate, fimbriate-ciliate. Stamen 1. Stigmas long, purple.—I. arundinacea *Cheesem. in Trans. N.Z. Inst.* xx (1888) 175 (*not of Cyr.*); *Man. N.Z. Fl.* (1906) 843; *Ill. N.Z. Fl.* ii (1914) t. 218.

KERMADEC ISLANDS: Cliffs on the north side of Sunday Island, abundant. *T. F. C., Miss Shakespear! W. R. B. Oliver!*

Closely allied to *I. exaltata* Brong., but a much smaller plant, with a smaller and less branched panicle, larger and broader spikelets on more clavate pedicels, and with the outer glume 5-nerved.

2. **ZOYSIA** Willd.

Small perennial creeping grasses. Culms branched at the base, rigid, erect. Leaves distichous, subulate, often pungent-pointed. Spikelets few, ovoid, 1-flowered, sessile or shortly pedicelled, not distichous, jointed on and closely appressed along a rigid notched unjointed rhachis, forming a short spike. Glumes 2; the outer one empty, broad, convolute, coriaceous, shining and nerveless; the inner flowering one included within the outer and much smaller than it, membranous, hyaline. Palea still smaller, short, nerveless, hyaline, sometimes wanting. Lodicules wanting. Stamens 3. Styles long, distinct; stigmas elongate. Grain free, enclosed within the hardened outer glume.

A small genus of 2 or 3 closely related species, found on the shores of southern and eastern Asia, Mauritius, Australia, and New Zealand.

1. **Z. pungens** *Willd. in Ges. Naturf. Fr. Neue Schr.* iii (1801) 441.—Rhizome long, creeping, branched, rigid and wiry. Culms numerous from the rhizome, often branched at the base, erect, rigid, glabrous, usually from 1 to 3 in. high, but sometimes taller and attaining 4–6 in. or even more. Leaves more or less spreading, subulate, flat or convolute, coriaceous; sheaths short, grooved, tipped with a few cilia; ligule wanting. Spike terminal, $\frac{1}{8}$–$\frac{3}{4}$ in. long; spikelets usually 3–5, but in small specimens often reduced to one, and in large ones sometimes as many as 7–9. Outer glume smooth and shining, convolute, coriaceous, tip often produced into a short awn. Flowering glume thin and hyaline, included within the outer glume.—*Hook. f. Fl. Nov. Zel.* i (1853) 312; *Handb. N.Z. Fl.* (1864) 324; *Benth. Fl. Austral.* vii (1878) 506; *Buch. N.Z. Grasses* (1879) t. 13A; *Cheesem. Man. N.Z. Fl.* (1906) 844. Rottboella uniflora *A. Cunn. Precur.* (1836) n. 267; *Raoul Choix* (1846) 39.

NORTH AND SOUTH ISLANDS: Abundant on sandy shores from the North Cape to Banks Peninsula and Okarito, less common in dry places inland, ascending to 2000 ft. at Lake Taupo and in Canterbury and Otago. Also not uncommon on the shores of Australia and Tasmania, extending northwards to India, Malacca, and China.

3. **PASPALUM** Linn.

Annual or perennial grasses, of various habit. Spikelets 1-flowered, orbicular or oblong, obtuse or rarely acute, not awned, sessile or very shortly pedicelled, arranged in one or two rows on one side of a slender

spike; spikes solitary, binate, digitate, or panicled. Glumes 3; 2 outer empty, membranous, usually subequal or rarely the lowest smaller or absent; upper or flowering glume much firmer, cartilaginous or almost coriaceous, 5–7-nerved. Palea similar in texture to the flowering glume but rather smaller, 2-nerved. Lodicules 2, cuneate. Stamens 3. Styles 2, distinct to the base, rather long. Grain ovoid or oblong, free, enclosed within the hardened flowering glume and palea.

Species about 200, scattered through the tropics of both hemispheres, but most abundant in America. The three species found in New Zealand are widely distributed.

Rhizome not creeping. Culms usually erect, 1–3 ft. Spikelets orbicular-ovoid, obtuse .. .. 1. *P. scrobiculatum.*

Rhizome long, creeping. Culms ascending, 6–24 in. Leaves flat, $\frac{1}{6}$–$\frac{1}{3}$ in. broad. Lateral spikes sessile. Spikelets oblong-ovoid, acute .. .. 2. *P. Digitaria.*

Rhizome long, creeping. Culms ascending, 2–8 in. Leaves involute, $\frac{1}{12}$ in. broad. Spikes all peduncled. Spikelets oblong, acute .. 3. *P. distichum.*

1. **P. scrobiculatum** *Linn. Mant.* i (1771) 29.—Rhizome short. Culms tufted, erect or decumbent at the base, usually sheathed throughout by the leaves, glabrous, 1–3 ft. high. Leaves linear or linear-lanceolate, acute or acuminate, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, glabrous or slightly hairy towards the base, flat or wrinkled; margins rough; ligule short, broad, membranous; sheaths rather lax. Spikes varying in number from 2 to 6, 1–2 in. long, alternate towards the top of the culm, usually rather distant, spreading or erect; rhachis $\frac{1}{12}$ in. broad, flat, margins ciliate. Spikelets in 2 or rarely 3–4 rows, imbricate, sessile or very shortly pedicelled, sometimes geminate on a common pedicel, ovoid-orbicular, obtuse, glabrous. Empty glumes subequal, thin and membranous, with a prominent midrib; the outer one with a single marginal vein on each side; the upper one with 2 marginal veins. Flowering glume similar in size and shape to the empty glumes, hard and coriaceous, brown, shining, minutely pitted. Palea coriaceous like the flowering glume, the margins produced into membranous inflected auricles.—*Hook. f. Fl. Nov. Zel.* i (1853) 291; *Handb. N.Z. Fl.* (1864) 323; *Benth. Fl. Austral.* vii (1878) 460; *Buch. N.Z. Grasses* (1879) t. 10A; *Cheesem. Man. N.Z. Fl.* (1906) 845. P. orbiculare *Forst. f. Prodr.* (1786) n. 35; *A. Rich. Fl. Nouv. Zel.* (1832) 140; *A. Cunn. Precur.* (1836) n. 266; *Raoul Choix* (1846) 39.

North Island: Auckland—Lowland stations from the North Cape to the East Cape and Taranaki, not uncommon.

An abundant plant in all warm countries outside America.

P. distichum L. Sp. 1816?

Ex. 2. **P. Digitaria** *Poir. Encycl. Suppl.* iv (1817) 316.—Rhizome long, branched, creeping and rooting. Culms erect or ascending, sheathed throughout by the leaves, glabrous, 6–24 in. high. Leaves numerous, distichous, 2–8 in. long, $\frac{1}{6}$–$\frac{1}{3}$ in. broad, flat, glabrous or sparingly hairy towards the base; ligules short, membranous, truncate; sheaths compressed, striate, margins pilose above. Spikes rather slender, 1–2 in. long, usually 2 but sometimes 3 or even 4, the lateral ones sessile or nearly so; rhachis flat, margins scabrid. Spikelets in 2 rows, nearly sessile, imbricate and appressed to the rhachis, ovate-oblong, acute, flattened, pale-green. Empty glumes equal, acute, membranous, pubescent or glabrous; the lower one 3-nerved; the upper 5-nerved, sometimes an additional minute empty glume is present at the base of the spikelet. Flowering glume coriaceous, smooth, shining,

Paspalum digitaria, Poir.

not native to N.Z. see T.N.Z.I. vol. 57, p. 66. (Ckn. & Allan).

Probably introduced into New Zealand, as in Australia, South Africa, India, and other countries, but the localities it affects give it the appearance of being indigenous. It is a common plant in many parts of America, from Virginia southwards. It can be distinguished from *P. distichum* by its greater size, much broader flat leaves, and by the lateral spikes being sessile.

P. vaginatum, Sw. See N. Am. Fl. 17(2). 1912. 95-6.

3. **P. distichum** *Linn. Syst. Nat.* (1759) 855.—Rhizome long, branched, creeping and rooting. Culms numerous, ascending, sheathed throughout by the leaves, glabrous, 2–8 in. high. Leaves numerous, distichous, 2–5 in. long by about $\frac{1}{12}$ in. broad, linear, acute, strict, spreading, usually involute; ligules short, truncate; sheaths thin, pale, loose, bearded at the mouth. Spikes 2, both peduncled and jointed on the top of the culm, usually spreading, 1–1½ in. long; rhachis narrower than the spikelets. Spikelets in 2 rows, sessile or nearly so, imbricate and appressed to the rhachis, oblong, acute or almost acuminate, flattened, glabrous, pale. Empty glumes equal, acute, thin and membranous, faintly 3–5-nerved. Flowering glume rather shorter than the empty glumes, coriaceous, pale, very indistinctly nerved. Palea coriaceous like the flowering glume, margins slightly auricled.—*Hook. f. Fl. Nov. Zel.* i (1853) 291; *Handb. N.Z. Fl.* (1864) 323; *Benth. Fl. Austral.* vii (1878) 460; *Buch. N.Z. Grasses* (1879) t. 10B; *Cheesem. Man. N.Z. Fl.* (1906) 846. Rottboellia uniflora (A. Cunn.) (1836) 371.

NORTH ISLAND: Auckland—Salt marshes from the North Cape to the Bay of Plenty and the Waikato River, abundant.

Widely distributed in all warm countries.

4. ISACHNE R. Br. 1810 Prodr 196.

Perennial or rarely annual grasses. Culms tufted, or decumbent or creeping at the base. Spikelets small or minute, loosely panicled, not at all or very obscurely articulate on the pedicels, 2-flowered; both flowers hermaphrodite, or the lower flower sometimes male, and the upper flower sometimes female. Empty glumes 2, subequal, persistent or separately deciduous, convex, membranous, awnless. Flowering glumes 2, rather smaller than the empty glumes, equal or the lower larger, convex or almost hemispherical, subcoriaceous. Palea as long as the flowering glume. Lodicules very minute. Stamens 3, rarely more. Grain free within the hardened glume and palea, generally falling away with them.

Species about 25, widely spread in most tropical or subtropical regions. The single New Zealand species ranges through Australia to India and China.

1. **I. australis** *R. Br. Prodr.* (1810) 196.—Culms slender, creeping or decumbent at the base, ascending above, glabrous or nearly so, 6–18 in. high. Leaves short, 2–6 in. long, $\frac{1}{6}$–$\frac{1}{4}$ in. broad, lanceolate or linear-lanceolate, acute, flat, minutely rough on both surfaces, margins scaberulous; sheaths smooth, ciliate at the mouth and on the margins above. Panicle erect, usually open, ovoid or pyramidal in outline, 2–4 in. long; branches numerous, sparingly divided, very slender, flexuose, minutely scaberulous. Spikelets all pedicelled, small, globose or nearly so, obtuse,

about $\frac{1}{12}$ in. long. Empty glumes membranous, glabrous, many-nerved. Flowering glumes firm and coriaceous, unequal in size; the lower much the larger, smooth, shining; upper sometimes minutely pubescent. Lower flower usually male; upper female. Palea coriaceous like the flowering glume.—*Hook. f. Fl. Nov. Zel.* i (1853) 291; *Handb. N.Z. Fl.* (1864) 324; *Benth. Fl. Austral.* vii (1878) 625; *Buch. N.Z. Grasses* (1879) t. 12; *Cheesem. Man. N.Z. Fl.* (1906) 847.

North Island: Abundant in swamps from the North Cape to the East Cape, Lake Taupo, and Taranaki. South Island: Tuamarina Swamp, near Picton, Marlborough, *J. H. Macmahon!* Sea-level to 1800 ft.

Greedily eaten by cattle. In summer and autumn it often affords a large amount of nutritious pasturage in swampy districts.

5. **PANICUM** Linn. 1735

Annual or perennial grasses, of very various habit. Spikelets lanceolate to ovate or broadly oblong, rarely globose, acuminate or acute or obtuse, articulate on the pedicel, laxly or densely paniculate, or very shortly pedicelled along one side of slender simple or branched spikes, seldom awned, glabrous or pubescent, never with bristles or spines at the base, with a single terminal hermaphrodite flower, sometimes with a male one below it. Glumes 4; the lowermost small, sometimes minute, empty; the 2nd and 3rd unequal or subequal, membranous, awnless or rarely awned, empty or the 3rd containing a male or rudimentary flower; 4th or flowering glume shorter or as long as the 3rd, firmer and more coriaceous, hardening in fruit. Palea like the flowering glume but smaller, 2-nerved. Lodicules 2. Grain enclosed in the hardened flowering glume and palea, oblong or ellipsoid; hilum punctiform.

As characterized above, this is a heterogeneous assemblage of about 400 species, found in all warm climates, but rare or absent in temperate countries. The single New Zealand species belongs to the section *Digitaria*, often kept as a distinct genus, in which the spikelets are almost sessile on one side of simple digitate spikes.

Trans. 57 (1926)

Ex. 1. **P. sanguinale** *Linn. Sp. Plant.* (1753) 57.—Annual. Culms creeping or rooting at the base, then spreading or erect, 6–18 in. long. Leaves 1–6 in. long by $\frac{1}{6}$–$\frac{1}{3}$ in. broad, flat, flaccid, pubescent or glabrous; sheaths thin, rather loose, often pilose and bearded at the nodes; ligules truncate, membranous. Spikes few or many, usually 3–6, varying in length from 1 to 4 in., crowded at the end of the culm, strict, spreading or erect; rhachis triquetrous or flattened, margins scaberulous. Spikelets geminate, one sessile, the other pedicelled, oblong-lanceolate, acute, greenish or purplish, $\frac{1}{15}$–$\frac{1}{12}$ in. long. Outer glume very minute, ovate, acute; 2nd small, ovate-lanceolate, 3-nerved, about $\frac{1}{2}$ the length of the flowering glume; 3rd rather longer than the flowering glume, oblong, acute, 6–7-nerved, the nerves often ciliate; 4th or flowering glume oblong, firm and subcoriaceous, acute or acuminate. —*Benth. Fl. Austral.* vii (1878) 469; *Cheesem. in Trans. N.Z. Inst.* xx (1888) 175; *Man. N.Z. Fl.* (1906) 848.

Kermadec Islands: Not uncommon in shady places, *T. F. C., W. R. B. Oliver!* North and South Islands: Abundant as a naturalized weed.

The Kermadec Islands plant, which is the only one which can be considered as indigenous, is referred by Hackel to the variety *microbachne* (*Panicum microbachne* Presl), and is a much more delicate and slender plant than the type, which is now plentiful as a naturalized weed in cultivated ground in most parts of New Zealand, as in all warm countries.

var. microbachne Haek. 1910

6. **OPLISMENUS** Beauv.

Weak, delicate grasses. Culms decumbent and often rooting at the base, branched, ascending above, leafy. Leaves thin, flat, broad, ovate to lanceolate. Spikelets 1-flowered, jointed on the pedicel, in little clusters on the branches of a simple panicle or spike. Glumes 4, the 3 outer membranous, empty or the 3rd with a rudimentary palea; the outer short, 3-nerved, with a long straight rigid awn; 2nd rather longer, awn short or almost wanting; 3rd the largest, 5-nerved, usually awnless; 4th or flowering glume rather shorter than the 3rd, lanceolate, firm, smooth, awnless, hardened in fruit. Palea coriaceous like the flowering glume. Stamens 3. Styles distinct. Grain oblong, enclosed within the hardened flowering glume and palea.

Species probably not more than 4 or 5, widely distributed in the warm regions of both hemispheres.

1. **O. undulatifolius** *Beauv. Agrost.* (1812) 54.—Culms prostrate and rooting at the base, ascending above, slender, weak, sparingly branched, 6–18 in. long. Leaves 1–3 in. long by $\frac{1}{4}$–$\frac{1}{3}$ in. broad, rarely more, lanceolate, acuminate, flat, glabrous or sparsely pilose; sheaths and nodes more or less pilose. Spike slender, 2–4 in. long; rhachis glabrous or pilose with spreading hairs. Spikelets small, $\frac{1}{12}$–$\frac{1}{8}$ in. long, in distant sessile clusters of 2–6 or the uppermost solitary, sometimes the lower clusters are produced into a short spike-like branch. Empty glumes 3, concave, membranous, nerved, pilose, the lower one with a stout rigid awn $\frac{1}{5}$–$\frac{1}{2}$ in. long. Flowering glume pale, coriaceous, nerveless, shining.—*Cheesem. Man. N.Z. Fl.* (1906) 848. O. setarius *Roem. and Schult. Syst.* ii (1817) 481; *Benth. Fl. Austral.* vii (1878) 492. O. aemulus *Kunth Rev. Gram.* i (1829) 44; *Hook. f. Fl. Nov. Zel.* i (1853) 292. Orthopogon aemulus *R. Br. Prodr.* (1810) 194. Panicum imbecille *Trin. Sp. Gram.* (1823–36) t. 191; *Hook. f. Handb. N.Z. Fl.* (1864) 323. Hekaterosachne elatior *Steud. Syn. Plant. Gram.* (1855) 118.

Kermadec Islands, North Island: Abundant throughout in shaded lowland stations. South Island: Recorded from Nelson (*Travers*) and Canterbury (*Lyall*), but I have seen no specimens.

An abundant plant in all warm climates, and barely distinct from the widely diffused *O. compositus* Beauv.

7. **CENCHRUS** Linn.

Annual or perennial grasses, usually tall. Leaves flat, flaccid. Spikelets narrow, with a single terminal hermaphrodite flower with or without a male flower below it, enclosed 1–4 together in an ovoid or globose involucre of numerous bristles or spines, the inner of which are broad and flattened, connate at the base and hardened in fruit; the involucres sessile in a terminal spike or raceme, and deciduous with the spikelets. Glumes 4; the outer much the smallest, sometimes minute, empty; 2nd equalling the 3rd or a little shorter, empty; 3rd usually containing a palea and sometimes 3 stamens; 4th or flowering glume rather shorter than the 3rd and more rigid. Stamens 3. Styles often connate at the base. Grain enclosed in the flowering glume and palea, free from them.

Species about 12, in the warm regions of both hemispheres and in temperate North America.

1. **C. calyculatus** *Cav. Ic.* v (1791–1901 39, t. 463.—Culms tufted, tall, stout, glabrous, 2–4 ft. high or more. Leaves long, linear-lanceolate, acuminate, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, flat, glabrous, scaberulous on the margins and veins above; sheaths long, rather lax; ligule split into numerous fine erect bristles. Spike 5–10 in. long by $\frac{1}{2}$ in. broad, stout, dense; rhachis angular, pubescent. Involucres about $\frac{1}{3}$ in. long, sessile or very shortly pedicelled, spreading or at length deflexed, broadly ovoid; inner bristles 8–12, connate at the base, compressed, unequal in length, sometimes one much longer than the rest, lower $\frac{2}{3}$ plumose with soft spreading hairs, upper $\frac{1}{3}$ rough and scabrous; outer bristles numerous, much shorter, spreading, subulate, scabrous throughout. Spikelets 1 or 2 within the involucres; outer empty glume half the length of the 2nd, ovate, acute, 1-nerved; 2nd rather shorter and broader than the 3rd, 3-nerved; 3rd with a palea and male flower, 5–7-nerved; 4th or flowering glume rather shorter and narrower, firmer in texture.—*Cheesem. in Trans. N.Z. Inst.* xx (1888) 175; *Man. N.Z. Fl.* (1906) 849. C. anomoplexis *Lab. Sert. Austr. Caled.* (1824–25) 14, t. 19.

Kermadec Islands: Sandy soil on the north side of Sunday Island, not common, *T. F. C., W. R. B. Oliver!* Also a native of New Caledonia and others of the Pacific islands.

8. **SPINIFEX** Linn. 1771 Mant.

Usually wide-creeping hard and stout branching grasses. Leaves long, involute, silky. Inflorescence dioecious. Male spikelets 2-flowered, sessile or shortly pedicelled, articulate on long erect spikes which are arranged in umbels surrounded by leafy spathaceous bracts. Glumes 4, all membranous, awnless: 2 lowest empty; 3rd and 4th each with a palea and 3 stamens. Female spikelets 1- or rarely 2-flowered, numerous, each one solitary at the base of long rigid pungent stellately spreading spines, surrounded by short lanceolate bracts, the whole inflorescence forming a large globose head. Glumes 4, subequal, narrow; 2 lowest empty; 3rd with a palea and sometimes with a rudimentary male flower; 4th with a female flower. Lodicules 2, large. Styles long, free; stigmas plumose. Grain free within the hardened flowering glume and palea.

A small genus of 4 species, 3 of which are found in Australia, one of them extending to New Zealand and New Caledonia, the fourth stretching from Ceylon and India to Java, China, and Japan.

1. **S. hirsutus** *Labill. Pl. Nov. Holl.* ii (1806) 81, t. 230, 231.—Stems creeping and rooting, branched, often many feet long, stout, knotted, silky or woolly. Leaves 1–2 ft. long, coriaceous, flexuous, densely clothed with soft silky hairs, margins strongly involute; sheaths long, broad, the inner smooth and shining; ligules split into a dense brush of erect silky hairs. Male spikes numerous, 2–4 in. long, arranged in a terminal umbel, with or without a cluster of 2–3 placed lower down the culm. Spikelets about $\frac{1}{3}$ in. long. Glumes silky, 5–7-nerved. Female heads large, globose, 6–12 in. diam.; spines very numerous, spreading all round, slender, subulate, pungent-pointed. Spikelets very narrow, acute or acuminate, $\frac{1}{2}$ in. long. Glumes 7–9-nerved.—*Hook. f. Fl. Nov. Zel.* i (1853) 292; *Handb. N.Z. Fl.* (1864) 322; *Benth. Fl. Austral.* vii (1878) 503; *Buch. N.Z. Grasses* (1879) 503; *Cheesem. Man. N.Z. Fl.* (1906) 850; *Cockayne Veg. N.Z.* (1921) t. 6. S. sericeus *R. Br. Prodr.* (1810) 198; *A. Rich. Fl. Nouv. Zel.* (1832) 122; *A. Cunn. Precur.* (1836) n. 268; *Raoul Choix* (1846) 40. Ixalum inerme *Forst. f. Prodr.* (1786) n. 564.

S. inermis B+S. ex Hk f. H.N.Z. 1. 292
also see Black Trans. R.S.S.A. 1933 : 143

NORTH ISLAND: Abundant on sandhills near the sea. SOUTH ISLAND: Nelson—Sandy shores of Blind Bay, *T. F. C.*; Cape Farewell, *H. H. Travers.* Canterbury—*Travers, Armstrong.*

Also common in Australia and New Caledonia. It is a valuable plant for fixing the surface of moving sand-dunes. Its use for that purpose is fully described in Dr. Cockayne's "Report on the Dune Areas of New Zealand." (Wellington, 1911.)

9. EHRHARTA Thunb. 1779

Perennial or annual grasses, of very varied habit. Leaves flat or convolute. Spikelets laterally compressed, 1-flowered, pedicellate, arranged in a panicle or simple raceme; rhachilla disarticulating above the 2 lowest glumes, obscurely produced above the flower. Glumes 5; the 2 lowest short, empty; 3rd and 4th longer, awned, frequently hairy at the base, also empty, 4th the longest, often with a callus at its base; 5th or flowering glume shorter, thinner, never awned, usually with a callus or tuft of hairs at its base. Palea narrow, keeled, finely and closely 2-nerved. Stamens 6 in the great majority of the species, 2 only in the New Zealand ones. Styles short or rather long; stigmas plumose. Grain ovoid or elliptic, compressed, enclosed within the flowering glume and palea, but free from them.

A genus of 27 species, all but the two following natives of South Africa, one of them extending northwards to eastern tropical Africa and Arabia.

Culms 6–18 in. Panicle 2–4 in., many-spiculate. Two lowest empty glumes acute .. .. 1. *E. Colensoi.*
Culms 1–5 in. Raceme small, of 2–5 spikelets. Two lowest empty glumes broad, obtuse .. .. 2. *E. Thomsoni.*

Microlaena Colensoi (Hook.f.) Petrie Trans. 43: 368 Sub. 4: 2. 472

1. **E. Colensoi** *Hook. f. Fl. Nov. Zel.* i (1853) 288, t. 65A.—Culms numerous, tufted, branched at the base, glabrous, many-noded, 6–18 in. high. Leaves numerous, distichous, suberect, the upper ones 4–6 in. long by $\frac{1}{6}$–$\frac{1}{5}$ in. broad, flat, faintly nerved, glabrous, tapering from the base to a slender point, the lowermost with the blades much reduced in size and almost scale-like; ligules very short, jagged; sheaths short, close, firm, thin, striate, glabrous. Panicles contracted, inclined or drooping, $1\frac{1}{2}$–4 in. long; rhachis slender, smooth; branches short, suberect, in small specimens sometimes reduced to single spikelets. Spikelets compressed, linear-oblong, about $\frac{1}{4}$ in. long; pedicels short, slender. Two lowest glumes about $\frac{1}{2}$ the length of the 3rd and 4th respectively, acuminate, 3–5-nerved; 3rd and 4th narrower, awned, silky-hairy at the base, 5–7-nerved. Flowering glume shorter than the 4th and about equal to the 3rd, oblong, obtuse, glabrous. Palea linear; rhachilla produced behind it as a minute appendage.—*Hook. f. Handb. N.Z. Fl.* (1864) 319; *Buch. N.Z. Grasses* (1879) t. 1; *Cheesem. Man. N.Z. Fl.* (1906) 851; *Ill. N.Z. Fl.* ii (1914) t. 219.

2. P. thomsoni Petrie

$\frac{1}{3}$–$\frac{1}{2}$ in. long, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, lanceolate, acute, strongly nerved; ligule reduced to a mere line; sheaths pale, strongly grooved. Inflorescence reduced to a short stout erect raceme of 2–5 spikelets, sometimes hardly longer than the leaves; pedicles short, stout, often appressed to the rhachis. Spikelets $\frac{1}{6}$–$\frac{1}{5}$ in. long, compressed. Two outer glumes small, subequal, broadly oblong or rounded, obtuse, less than $\frac{1}{3}$ as long as the 3rd and 4th respectively; 3rd and 4th ovate-lanceolate, rigid, keeled, awned, 5-nerved, silky at the base, keel and awns minutely scabrid. Flowering glume shorter, oblong, obtuse or subacute, 3–5-nerved. Palea linear. Stamens 1–2.—*Cheesem. Man. N.Z. Fl.* (1906) 852.

SOUTH ISLAND: Nelson—Mount Rochfort, *Dr. Gaze! W. Townson!* Otago—Longwood Range, *T. Kirk!* STEWART ISLAND: Port Pegasus, *Thomson* and *Petrie! T. Kirk!* Rakiahua, *P. Goyen!* AUCKLAND ISLANDS: *F. R. Chapman!* Sea-level to 4000 ft.

A very curious and distinct little species.

10. MICROLAENA R. Br.

Slender perennial grasses; culms simple or branched. Leaves flat or convolute when dry. Spikelets laterally compressed, 1-flowered, pedicellate, arranged in a narrow lax panicle; rhachilla disarticulating above the 2 outer glumes. Glumes 5; the 2 outer very small, persistent; 3rd and 4th long, narrow, produced into long awns, the 4th much the longest; 5th or flowering glume shorter, acute, not awned. Palea linear. Lodicules 2, rather large, thin. Stamens 4 or 2. Styles distinct; stigmas plumose. Grain enclosed within the flowering glume and palea but free from them.

A small genus of 7 species, confined to Australia and New Zealand. One of the New Zealand species is also found in Australia, the remaining three are endemic.

* The two outer glumes distant from the 3rd and 4th.

Leaves flat, thin, $\frac{1}{8}$–$\frac{1}{5}$ in. broad. Panicle 3–9 in., narrow. Stamens 4 .. .. 1. *M. stipoides.*

** The 2 outer glumes not distant from the 3rd and 4th.

Culms not branched. Leaves broad, $\frac{1}{4}$–$\frac{1}{2}$ in. Panicles 1–2 ft., compound. Stamens 2 .. .. 2. *M. avenacea.*

Culms decumbent at the base. Leaves $\frac{1}{8}$–$\frac{1}{4}$ in. broad. Panicles 5–9 in. long, narrow. Stamens 2 .. .. 3. *M. Carsei.*

Culms branched. Leaves $\frac{1}{10}$–$\frac{1}{8}$ in. broad. Panicle reduced to a simple raceme 1–3 in. long, rarely branched at the base. Stamens 4 .. .. 4. *M. polynoda.*

1. **M. stipoides** *R. Br. Prodr.* (1810) 210.—Rhizome creeping and rooting, branched. Culms numerous from the rhizome, often branched below, erect or ascending, slender, glabrous, 1–2 ft. high or more. Leaves rather short, 3–9 in. long, $\frac{1}{8}$–$\frac{1}{5}$ in. broad, thin, flat, acute, glabrous, finely scaberulous on the midrib beneath; ligules very short, reduced to a mere rim; sheaths thin, usually finely pubescent. Panicle narrow, slender, lax, branched at the base, 3–9 in. long; branches erect, capillary. Spikelets narrow, about $\frac{1}{3}$ in. long without the awns, on filiform pedicels. Two outer glumes minute, persistent, many times smaller than the 3rd and 4th, and separated from them by an elongated bearded portion of the rhachilla; 3rd and 4th long and narrow, produced into slender awns, the 4th longer than the 3rd, its awn often more than 1 in. long, nerves 5–7, with the awns rough and scabrid. Flowering glume much shorter, acuminate but

Zotov (Trans 73: 235) places M. Carsei as M. avenacea var. carsei (Cheesm.) Zot.

not awned, faintly 7-nerved. Palea linear. Lodicules large. Stamens 4. —*Hook. f. Fl. Nov. Zel.* i (1853) 289; *Handb. N.Z. Fl.* (1864) 320; *Benth. Fl. Austral.* vii (1878) 552; *Buch. N.Z. Grasses* (1879) t. 2; *Cheesem. Man. N.Z. Fl.* (1906) 852. Enharta stip. habit. 1804 i—16. t 118.

North Island: Not uncommon throughout, but most plentiful in lowland districts. South Island, Stewart Island: In various localities, chiefly near the sea. Sea-level to 2000 ft.

Widely distributed in Australia, ranging from Queensland to Tasmania and West Australia. It is a most valuable pasture and lawn grass, deserving of far more attention than has hitherto been given to it.

(Lam)

2. **M. avenacea** *Hook. f. Handb. N.Z. Fl.* (1864) 320.—Culms tufted, tall, stout, erect or spreading, compressed, glabrous, 1–4 ft. high. Leaves mostly towards the base of the culms and shorter than them, broad, flat, $\frac{1}{4}$–$\frac{1}{2}$ in. diam., glabrous, striate, scaberulous on the margins and principal veins; sheaths long, smooth, deeply striate; ligules broad, bearded at the sides. Panicle 1–2 ft. long, sparingly branched, compound, lax, nodding, pale-green; branches long, slender, almost capillary, angled, scaberulous. Spikelets very narrow, about $\frac{1}{3}$ in. long without the awns, usually 1 in. with them; pedicles slender, thickened above. Two lowest glumes small, many times less than the 3rd and 4th, not separated from them by a conspicuous interspace as in *M. stipoides*, 1-nerved, obtuse, sometimes notched at the tip, the outer one $\frac{1}{2}$ the length of the 2nd; 3rd and 4th long, narrow, empty, 5–7-nerved, rough and scabrous, hairy at the base, produced into long awns. Flowering glume much shorter than the 4th, acuminate but not awned, faintly 5–7-nerved. Palea linear, acuminate, 1-nerved. Stamens 2.—*Buch. N.Z. Grasses* (1879) t. 3; *Cheesem. Man. N.Z. Fl.* (1906) 853. Diplax avenacea *Raoul Choix* (1846) 11, t. 3; *Hook. f. Fl. Nov. Zel.* i (1853) 289. Ann. Sci Nat. 1844: 2: 116.

North and South Islands, Stewart Island: Abundant in forests throughout. Auckland Islands: In forest, but not common, *J. S. Tennant!* Sea-level to 2500 ft. December–January.

3. **M. Carsei** *Cheesem. in Trans. N.Z. Inst.* xlvii (1915) 47.—Rhizome slender, stoloniferous. Culms slender, prostrate or ascending at the base, erect above, 6–18 in. high, smooth and glabrous, 1–3-noded, often rooting from the lower nodes and emitting fascicles of both barren and flowering shoots. Leaves short or long, 6–12 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, gradually tapering to a fine point, thin, flat, glabrous, striate, faintly scaberulous on the principal veins and margins; sheaths long, smooth, compressed, strongly grooved; ligules short, thin, furnished with a few long hairs at the sides. Panicle 5–9 in. long, rarely more, compound, but much more sparingly branched than in *M. avenacea* and much narrower and more rigid, pale-green; branches erect, appressed to the main rhachis, slender, angled, scaberulous. Spikelets narrow, compressed, $\frac{2}{3}$–$\frac{3}{4}$ in. long with the awns. Two lowest glumes small, many times shorter than the 3rd and 4th, not separated from them by a conspicuous interspace, the lowest $\frac{1}{3}$ the length of the 2nd, which is irregularly notched at the top; 3rd and 4th long, narrow, empty, unequal, the 4th rather more than twice the length of the 3rd, 5–7-nerved, scabrid, hairy at the base, long-awned at the tip. Flowering-glume much shorter than the 4th, acuminate but not awned, faintly 5–7-nerved. Palea linear, 1-nerved. Stamens 2.

NORTH ISLAND: Damp forests at Kaiaka, Mongonui County, *H. Carse!* Closely allied to *M. avenacea*, but smaller in all its parts, and with a very different habit of growth. Leaves shorter and narrower. Panicle also shorter and narrower, and much less divided. Spikelets smaller, with shorter pedicels and much shorter awns.

4. **M. polynoda** *Hook. f. Handb. N.Z. Fl.* (1864) 320.—Culms 3–8 ft. long, much branched, straggling, often scrambling among shrubs and bushes, hard, solid, terete, as thick as a goose-quill at the base, quite glabrous, conspicuously swollen at the nodes. Leaves numerous, rather distant, the lowermost reduced to sheaths, upper 3–9 in. long, $\frac{1}{10}$–$\frac{1}{6}$ in. broad, linear, finely acuminate, flat, striate, margins scaberulous; sheaths smooth, grooved; ligules short, with a few long hairs on each side. Panicle usually reduced to a simple raceme 1–2$\frac{1}{2}$ in. long with few spikelets, but sometimes 3–3$\frac{1}{2}$ in., the lower portion with 1 or 2 short erect 2–3-spiculate branches. Spikelets narrow, compressed, $\frac{1}{2}$–$\frac{3}{4}$ in. long with the awns. Two lowest glumes small, whitish, many times less than the 3rd and 4th, not separated from them by a distinct interspace, the lowest $\frac{1}{3}$ the length of the 2nd; 3rd and 4th narrow, unequal, empty, awned, rough and scabrous on the sides and awn, hairy at the base. Flowering glume shorter than the 4th, acuminate, 5–7-nerved. Palea linear, 1-nerved. Stamens 4.—*Buch. N.Z. Grasses* (1879) t. 4; *Cheesem. Man. N.Z. Fl.* (1906) 853. M. ramosissima *Col. in Trans. N.Z. Inst.* xxi (1889) 105. Diplax polynoda *Hook f. Fl. Nov. Zel.* i (1853) 290.

Kirk;* Te Aroha, *Adams;* Muriwai, *T. F. C.* Hawke's Bay—Dannevirke, base of the Ruahine Range, *Colenso!* Weber, Feilding, *B. C. Aston.* SOUTH ISLAND: Nelson—Motueka Valley, *T. F. C.* Canterbury—*Armstrong;* Banks Peninsula, *Cockayne.* Otago—Near Dunedin, *Buchanan! Petrie!* Sea-level to 1500 ft. December–January.

11. HIEROCHLOE (Gmel. 1747) R. Br. 1810

Erect sweet-scented perennial grasses. Leaves flat. Spikelets in an open or close panicle, laterally compressed, shining, with 1 terminal hermaphrodite flower and 1–2 male flowers below it. Glumes 5; 2 outer empty, equal or nearly so, acute, keeled, scarious, 1–3-nerved; 3rd and 4th subsimilar, often shortly awned, each enclosing a narrow palea and usually 3 stamens; 5th rather smaller, obtuse or mucronate, 5-nerved, enclosing a hermaphrodite flower and a linear 1–2-nerved palea. Lodicules 2. Styles free; stigmas plumose. Grain oblong, free within the slightly indurated flowering glume and palea.

Species 12 or 13, distributed throughout the temperate and frigid zones of both hemispheres. All the species have a vanilla-like fragrance when drying. Of the three found in New Zealand, one is widely spread in the South Temperate Zone, another extends to Victoria and Tasmania, the third is endemic in the Auckland Islands.

* Two outer glumes about equal to the florets.

Culms 2–3 ft. Leaves long, $\frac{1}{4}$–$\frac{1}{2}$ in. broad. Spikelets $\frac{1}{4}$ in. long; outer glumes equalling or slightly exceeding the florets .. 1. *H. redolens.*

Culms 6–18 in. Leaves short, $\frac{1}{12}$–$\frac{1}{5}$ in. broad. Spikelets $\frac{1}{5}$ in. long; outer glumes usually slightly shorter than the florets .. .. 2. *H. Fraseri.*

** Two outer glumes much longer than the florets.

Culms 1–2 ft. Leaves involute, subcoriaceous. Spikelets $\frac{1}{3}$ in. long 3. *H. Brunonis.*

1. **H. redolens**, *R. Br. Prodr.* (1810) 209.—Culms tufted, leafy, decumbent at the base, erect or ascending above, stout or rather slender, 1½–3 ft. high or even more. Leaves numerous, shorter than the culms or almost equalling them, ¼–½ in. broad, flat, deeply striate, smooth or minutely scaberulous, bright shining-green; sheaths long, compressed, deeply striate; ligules broad, scarious. Panicle pale yellowish-brown, shining, open or dense, inclined or nodding, very variable in size, usually from 4 to 12 in. long, more rarely elongated and reaching 14 or 18 in.; rhachis slender, glabrous; branches very slender, almost capillary, more or less hairy or almost glabrous, lower 2–3 in. long. Spikelets ¼ in. long and broad, shortly pedicellate; pedicels shorter than the spikelets, pilose. Glumes all thin and membranous; outer 2 equalling or sightly exceeding the 3rd and 4th, ovate, acuminate, with a stout continuous midrib and a short basal lateral vein on each side; 3rd and 4th each enclosing a male flower, ovate-oblong, obtuse, 5-nerved, pubescent, silky-ciliate on the margins and keel, with a short awn from the back a little below the tip; 5th smaller than the 4th, glabrous below, slightly hairy above, mucronate or very shortly awned. Palea linear-oblong, 1–2-nerved.—*Hook. f. Fl. Antarct.* i (1844) 92; *Fl. Nov. Zel.* i (1853) 300; *Handb. N.Z. Fl.* (1864) 321; *Fl. Tasm.* ii (1860) 108; *Benth. Fl. Austral.* vii (1878) 558; *Buch. N.Z. Grasses* (1879) t. 6; *Cheesem. Man. N.Z. Fl.* (1906) 855. Nomen nudum.
H. antarctica *R. Br. Prodr.* (1810) 209. Holcus redolens *Forst. f. Prodr.* (1786) n. 563. Torresia redolens *Roem. and Schult. Syst.* ii (1817) 516; *A. Cunn. Precur.* (1836) n. 269.

North and South Islands, Stewart Island, Chatham Islands, Campbell Island: Abundant in moist places throughout. Sea-level to 4000 ft.

Also in Fuegia, Tasmania, and Victoria. It varies much in size and degree of robustness, and appears to pass by easy gradations into the next species.

(Forst.f.?)

2. **H. Fraseri**, *Hook. f. Fl. Antarct.* i (1844) 93.—Smaller and more slender than *H. redolens*, with narrower leaves. Culms tufted, sometimes densely so, slender, quite smooth and glabrous, 6–18 in. high, rarely more. Leaves much shorter than the culms, 3–9 in. long, strict, erect, flat, ⅛–½ in. broad, quite smooth; ligules broad, scarious. Panicle pale yellowish-brown, often tinged with purple, short, ovate, open, shining, 1½–4 in. long; branches often few, capillary, usually glabrous. Spikelets ⅛ in. long and broad, shortly pedicelled; pedicels glabrous or more or less bearded. Glumes all thin and membranous; outer 2 usually slightly shorter than the 3rd and 4th, obtuse or subacute, 3-nerved but the lateral nerves often short; 3rd and 4th each enclosing a male flower, oblong, obtuse, 5-nerved, pubescent, margins silky-ciliate for their whole length, awn short, straight, from the back a little below the tip; 5th smaller than the 4th, glabrous or nearly so at the base, pubescent or ciliate above, tip produced into a short awn. Palea linear, 1–2-nerved.—*Cheesem. Man. N.Z. Fl.* (1906) 855; *Ill. N.Z. Fl.* ii (1914) t. 220; H. redolens *var.* Fraseri *Benth. Fl. Austral.* vii (1878) 559. H. borealis *Hook. f. Fl. Nov. Zel.* i (1853) 300; *Fl. Tasm.* ii (1862) 108 (*not of Roem. and Schult.*); *Buch. N.Z. Grasses* (1879) t. 7.

( ) Zotov. comb. nov.

Var. **recurvata** *Hack. MS.*—Awn of 4th glume inserted on the middle of the back of the glume, slightly geniculate above. Spikelets rather larger.

North and South Islands, Stewart Island: Not uncommon in mountain districts from the East Cape, Mount Egmont, and the Central Volcanic Plateau southwards. Sea-level to 4500 ft.

See T. Kirk Trans 14:1882:385

Also in Tasmania. A puzzling plant, large states of which cannot be clearly separated from *H. redolens*, although usually differing in the smaller size, slender habit, shorter and more open panicles, and smaller spikelets, with the empty glumes rather shorter than the 3rd and 4th. Sir J. D Hooker referred it to *H. borealis* in the Flora, and to *H. alpina* in the Handbook. But Professor Hackel remarks that it differs from both of these species in the short blunt outer glumes, and from *H. alpina*, in addition, in the much longer branches of the panicle, and in the awn of the 4th glume being usually inserted just beneath the apex and not geniculate. Var. *recurvata* approaches *H. alpina* in the awn of the 4th glume, but the panicle, &c., is different.

3. **H. Brunonis** *Hook. f. Fl. Antarct.* i (1844) 93, t. 52.—Culms laxly tufted, inclined at the base, erect above, glabrous, leafy, 1–1½ ft. high. Leaves shorter than the culms, ⅛–⅓ in. broad, rather strict, suberect, linear-subulate, involute, subcoriaceous, glabrous, deeply striate on the inner face, pale shining-green ; sheaths compressed, striate ; ligules ovate, scarious. Panicle inclined or nodding, shining, rather dense, ovate-lanceolate, 3–5 in. long by 1–1½ in. broad ; rhachis slender, glabrous ; branches suberect, the lower about 1 in. long. Spikelets ⅓ in. long, pedicelled ; pedicels sparsely pilose. Glumes all membranous ; outer 2 much longer than the 3rd and 4th, sometimes nearly twice as long, lanceolate, long-acuminate, glabrous, 3-nerved ; 3rd and 4th each enclosing a male flower, ovate-oblong, obtuse, 5-nerved, deeply bifid at the tip, pubescent or pilose, margins silky-ciliate, awn rather long, rising from the back a little distance below the base of the lobes ; 5th similar to the 4th but smaller and much less pubescent, usually glabrous at the base. Palea linear-oblong, 1–2-nerved.—*Handb. N.Z. Fl.* (1864) 322 ; *Cheesem. Man. N.Z. Fl.* (1906) 856.

Auckland and Campbell Islands : Abundant on the hills, *Sir J. D. Hooker, T. Kirk! Buchanan!* Sea-level to 1400 ft.

The long empty glumes readily separate this from any form of *H. redolens*.

12. **STIPA** Linn. 1735

Tufted perennial grasses. Leaves usually convolute, rarely flat. Spikelets narrow, terete, 1-flowered, in an open or contracted panicle ; rhachilla disarticulating above the 2 outer glumes. Glumes 3 ; the 2 outer empty, usually persistent, keeled, acute, rarely awned ; 3rd or flowering glume rigid, convolute, terete, 5–7-nerved, usually with a bearded callus at the base, tapering upwards into an entire or minutely 2-lobed tip, with a long terminal geniculate awn often spirally twisted below the bend. Palea 2-nerved, enclosed within the flowering glume. Lodicules usually 3, large. Stamens 3, seldom fewer. Styles distinct, rather short. Grain narrow, terete, tightly enclosed by the hardened flowering glume and palea.

A genus of over 100 species, spread over the temperate and tropical regions of both hemispheres. Two of the New Zealand species extend to Australia, the third is endemic.

Tall, 2–5 ft. Panicle 1–2½ ft., lax, nodding. Spikelets minute, 1/10–⅛ in. Stamen 1	1. *S. arundinacea.*
Densely tufted, 1–3 ft. Leaves long, terete. Panicle 4–9 in., narrow, strict, erect. Spikelets ¾ in.	2. *S. teretifolia.*
Tufted, 1–2 ft. Leaves short, filiform. Panicle 4–8 in., lax, erect. Spikelets ¼ in.	3. *S. setacea.*

(1844.)

1. **S. arundinacea** *Benth. in Journ. Linn. Soc.* xix (1881) 81.—Rhizomes short, creeping, scaly. Culms very densely tufted, tall, erect, nodding, rigid, quite glabrous, 2–5 ft. high. Leaves from the distant nodes of

oryzopsis rigida (Richard) Zotov Trans 75 : 235.
Agrostis rigida Rich. 1832 p. 124 n. 191.

the culms, the lowermost reduced to appressed sheaths, upper 6–12 in. long, $\frac{1}{8}$–$\frac{1}{5}$ in. broad, coriaceous, flat or involute, margins and midrib slightly scaberulous; sheaths very long, closely appressed, finely ciliate along the margins; ligules short, truncate. Panicles very large and lax, nodding, 1–2½ ft. long; rhachis very slender, glabrous; branches in distant whorls of 5–8, capillary, again compound, spreading, finely scaberulous, 3–6 in. long. Spikelets minute, $\frac{1}{10}$–$\frac{1}{8}$ in. long, greenish-purple. Two outer glumes almost equal, lanceolate, acuminate, membranous, scaberulous along the keel, lower 1-nerved, upper 3-nerved; 3rd or flowering glume much shorter, sessile on a short glabrous callus, rigid, convolute, pubescent towards the tip; awn slender, scabrid, deciduous, about $\frac{1}{3}$ in. long. Palea linear-oblong, 2-nerved. Stamen 1.—*Cheesem. Man. N.Z. Fl.* (1906) 857. Apera arundinacea *Hook. f. Fl. Nov. Zel.* i (1853) 295, t. 67; *Handb. N.Z. Fl.* (1864) 326; *Buch. N.Z. Grasses* (1879) t. 17. A. purpurascens *Col. in Trans. N.Z. Inst.* xxi (1889) 106. Benth. 1881. p 81.

North and South Islands: Auckland—East Cape, *Bishop Williams.* Hawke's Bay—Petane, *A. Hamilton!* Dannevirke and Cape Turnagain, *Colenso!* Wellington—Wairarapa, *Buchanan!* near Masterton, *W. Townson!* South Karori, *T. Kirk.* Nelson—Foxhill, Wangapeka, *T. F. C.* Marlborough—Picton Water Reserve, *J. H. Macmahon;* Pelorus Valley, *Rutland!* Canterbury—Banks Peninsula, at Pigeon Bay and Long Bay, *R. M. Laing!* Akaroa, *Raoul, T. Kirk!* Rakaia Gorge, *H. H. Allan.* Otago—Near Dunedin, *Buchanan! Petrie! Thomson!* Horse Ranges and Kaitangata, *Petrie.* Sea-level to 1500 ft.

A very handsome species. It is closely allied to *S. verticillata* Nees (*Streptachne ramosissima* Trin.), an Australian species which is often grown in gardens, and which has established itself in several localities, but which differs in the rather larger spikelets with a much longer persistent awn, and in having 3 stamens.

see Kirk. Trans 14 : 1882 : 385

2. **S. teretifolia** *Steud. Syn. Pl. Gram.* (1855) 128.—Culms densely tufted, forming large tussocks, rigid, erect, smooth and polished, quite glabrous, 1½–3 ft. high. Leaves longer or shorter than the culms, slender, smooth, rigid, terete, about $\frac{1}{30}$ in. diam., tips acicular; sheaths long, margins scarious; ligules membranous, entire. Panicle narrow, strict, erect, 4–9 in. long; rhachis smooth; branches few, erect, capillary, and with the pedicels glabrous. Spikelets narrow, about $\frac{3}{4}$ in. long without the awn. Two outer glumes subequal, lanceolate, acuminate, finely 3-nerved, membranous, pale whitish-green; 3rd or flowering glume much shorter, rigid and convolute, lanceolate, acuminate, densely clothed with long silky hairs, shortly bifid at the apex; awn from between the lobes, often over 1 in. long, curved or abruptly bent, minutely pubescent. Palea $\frac{3}{4}$ the length of the flowering glume, linear, silky, 2-nerved. Stamens 3.—*Benth. Fl. Austral.* vii (1878) 567; *Cheesem. Man. N.Z. Fl.* (1906) 857. Dichelachne stipoides *Hook. f. Fl. Nov. Zel.* i (1853) 294, t. 66; *Handb. N.Z. Fl.* (1864) 325; *Buch. N.Z. Grasses* (1879) t. 14.

North Island: Rocky or sandy places near the sea, from the North Cape to the Bay of Plenty and Raglan, abundant.

Not uncommon in Australia and Tasmania. Hooker quotes *Agrostis rigida* A. Rich. as a synonym, but Richard's description does not suit, and his plant was gathered in the French Pass, near Nelson, far beyond the southern limit of *S. teretifolia.*

3. **S. setacea** *R. Br. Prodr.* (1810) 174.—Culms tufted, slender, wiry, erect, glabrous, 1–2 ft. high. Leaves numerous towards the base of the

n, erect,
narrow,

North Island: Rocky or sandy places near the sea, from the North Cape to the Bay of Plenty and Raglan, abundant.

Not uncommon in Australia and Tasmania. Hooker quotes *Agrostis rigida* A. Rich. as a synonym, but Richard's description does not suit, and his plant was gathered in the French Pass, near Nelson, far beyond the southern limit of *S. teretifolia.*

3. **S. setacea** *R. Br. Prodr.* (1810) 174.—Culms tufted, slender, wiry, erect, glabrous, 1–2 ft. high. Leaves numerous towards the base of the culms and much shorter than them, very slender, almost filiform, erect, smooth, involute; sheaths closely appressed, smooth; ligules narrow,

membranous. Panicle lax, strict, erect, glabrous, 4–8 in. long; rhachis smooth; branches whorled, capillary, each with 2–5 spikelets; pedicels minutely scaberulous. Spikelets $\frac{1}{4}$ in. long without the awn, pale whitish-green. Two outer glumes almost equal, lanceolate, acuminate, very thin and membranous, almost hyaline, glabrous; 3rd or flowering glume much shorter, rigid, convolute, brownish, densely villous, entire at the tip; awn very slender, glabrous, 1–1$\frac{1}{2}$ in. long. Palea linear, silky, 2-nerved. Stamens 3.—*Hook. f. Fl. Tasm.* ii (1860) 110, t. 157B; *Benth. Fl. Austral.* vii (1878) 568; *T. Kirk in Trans. N.Z. Inst.* xiv (1882) 386; *Petrie in Trans. N.Z. Inst.* xix (1887) 326; *Cheesem. Man. N.Z. Fl.* (1906) 858. S. Petriei *Buch. N.Z. Grasses* (1879) t. 17, ii.

SOUTH ISLAND: Otago—Cromwell, Kurow, Duntroon, and other localities in the interior of Otago, *Petrie!* 500–1500 ft.

A common Australian plant, stretching from Queensland to Tasmania. It is probably naturalized in New Zealand.

13. **ECHINOPOGON** Beauv.

An erect or ascending glabrous grass. Leaves flat. Spikelets 1-flowered, crowded in a short and dense spike-like panicle; rhachilla disarticulating above the 2 outer glumes, produced beyond the flower into a short bristle. Glumes 3; 2 outer subequal, persistent, empty, awnless, keeled, acute; 3rd or flowering glume broad, thin, 5-nerved, 3-lobed at the tip, the lateral lobes short and acute, the middle one produced into a straight stiff awn. Palea shorter than the flowering glume, narrow, 2-nerved. Lodicules 2. Stamens 3. Styles distinct; stigmas shortly plumose. Grain free within the flowering glume.

The genus is confined to the following species, which has a wide range in Australia as well as in New Zealand.

1. **E. ovatus** *Beauv. Agrost.* (1812) 42, t. 9.—Culms laxly tufted, decumbent at the base, erect above, slender, stiff, minutely scabrid above, 9–24 in. high. Leaves 1–6 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, flat, striate, margins and both surfaces harsh and scabrid; sheaths rather long, closely appressed, deeply striate, scabrid with reversed projections; ligule short, membranous, lacerate. Spike-like panicle varying in size from $\frac{1}{2}$–1$\frac{1}{2}$ in. long, ovoid-globose to narrow-oblong, bristling with the long awns; branches short, densely packed. Spikelets compressed, $\frac{1}{10}$–$\frac{1}{8}$ in. long without the awns. Two outer glumes subequal, lanceolate, acute, sharply keeled, keel very prominent, green, ciliate; 3rd or flowering glume equalling or slightly exceeding the empty glumes, broad, furnished at the base with a pencil of silky hairs, awn rigid, scabrous, $\frac{1}{4}$–$\frac{1}{3}$ in. long. Palea linear-oblong, 2-nerved, with a hairy bristle-like continuation of the rhachilla at its back.—*Hook. f. Fl. Nov. Zel.* i (1853) 298; *Handb. N.Z. Fl.* (1864) 325; *Benth. Fl. Austral.* vii (1878) 599; *Buch. N.Z. Grasses* (1879) t. 13B; *Cheesem. Man. N.Z. Fl.* (1906) 859. Agrostis ovata *Forst. f. Prodr.* (1786) n. 40; *A. Rich. Fl. Nouv. Zel.* (1832) 128; *A. Cunn. Precur.* (1836) 247; *Raoul Choix* (1846) 39. Cinna ovata *Kunth Rev. Gram.* i (1829) 208. Hystericina alopecuroides *Steud. Syn. Pl. Gram.* (1855) 35.

NORTH AND SOUTH ISLANDS: Not uncommon in dry places throughout. Sea-level to 2500 ft.

14. **ALOPECURUS** Linn. 1735

Annual or perennial grasses. Leaves flat. Spikelets strongly laterally compressed, 1-flowered, densely crowded in a cylindric spike-like panicle, articulated on the top of the very short pedicels. Glumes 3; the 2 outer subequal, often connate below, sharply keeled, acute or obtuse, not awned, often fringed on the keels; 3rd or flowering glume about as long as the outer glumes, convolute, hyaline, usually with a slender bent dorsal awn. Palea generally wanting. Lodicules absent. Stamens 2 or 3. Styles distinct or connate. Grain laterally compressed, free within the flowering glume and palea.

Species about 20, in the temperate and cool regions of both hemispheres, several of them excellent fodder-grasses. The single New Zealand species is widely distributed.

E? 1. **A. geniculatus** *Linn. Sp. Plant.* (1753) 60.—Culms creeping and rooting at the base, erect above, rather slender, glabrous, 9–18 in. high. Leaves short, soft, flat, $\frac{1}{8}$–$\frac{1}{6}$ in. broad; upper sheaths long, grooved, more or less inflated; ligules long, membranous. Spike 1–2 in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, dense, cylindric, greenish-yellow; branches short, the ultimate [illegible] Spikelets numerous, closely imbricating, connate at along the ones, thin, twice the hers linear, . *Fl.* (1864) 879) t. 5;

Alopecurus geniculatus, Linn.

not native to N.Z. see T.N.Z.I.

vol. 57, p. 61. (Ckn. & Allan).

NORTH ISLAND: Auckland—Lower Waikato, *T. Kirk!* [illegible] pe, *T. F. C.*; East Cape district, *Bishop Williams!* Hawke's Bay—*Colenso!* Wellington—Wairarapa, *Buchanan!* near Wellington, *T. Kirk!* SOUTH ISLAND: Not uncommon in marshy places throughout. Sea-level to 3500 ft. *Marsh Foxtail.*

An abundant grass in marshy places in most temperate regions. The allied species *A. pratensis* (Meadow Foxtail) and *A. agrestis* (Slender Foxtail), descriptions of which will be found in any British Flora, have become naturalized in several localities in both Islands.

15. **SPOROBOLUS** R. Br. 1810

Annual or perennial grasses, of very various habit. Leaves flat or convolute. Spikelets small, often minute, 1-flowered, awnless, arranged bscurely ower or 2 outer g glume ; as the icules 2, e flower-

Sporobolus indicus, RBr.

NORTH AND SOUTH ISLANDS: Not uncommon in dry places throughout. Sea-level to 2500 ft.

14. **ALOPECURUS** Linn. 1735

Annual or perennial grasses. Leaves flat. Spikelets strongly laterally compressed, 1-flowered, densely crowded in a cylindric spike-like panicle, articulated on the top of the very short pedicels. Glumes 3; the 2 outer subequal, often connate below, sharply keeled, acute or obtuse, not awned, often fringed on the keels; 3rd or flowering glume about as long as the outer glumes, convolute, hyaline, usually with a slender bent dorsal awn. Palea generally wanting. Lodicules absent. Stamens 2 or 3. Styles distinct or connate. Grain laterally compressed, free within the flowering glume and palea.

Species about 20, in the temperate and cool regions of both hemispheres, several of them excellent fodder-grasses. The single New Zealand species is widely distributed.

E? 1. **A. geniculatus** *Linn. Sp. Plant.* (1753) 60.—Culms creeping and rooting at the base, erect above, rather slender, glabrous, 9–18 in. high. Leaves short, soft, flat, $\frac{1}{8}$–$\frac{1}{6}$ in. broad; upper sheaths long, grooved, more or less inflated; ligules long, membranous. Spike 1–2 in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, dense, cylindric, greenish-yellow; branches short, the ultimate ones bearing a single spikelet. Spikelets numerous, closely imbricating, much compressed, $\frac{1}{10}$–$\frac{1}{8}$ in. long. Two outer glumes slightly connate at the base, obtuse or subacute, membranous, pubescent, ciliate along the keel; 3rd or flowering glume rather shorter than the empty ones, thin, convolute, truncate and erose at the tip; awn slender, not twice the length of the glume, almost basal, straight or recurved. Anthers linear, orange-yellow.—*Hook. f. Fl. Nov. Zel.* i (1853) 290; *Handb. N.Z. Fl.* (1864) 321; *Benth. Fl. Austral.* vii (1878) 555; *Buch. N.Z. Grasses* (1879) t. 5; *Cheesem. Man. N.Z. Fl.* (1906) 859.

North Island: Auckland—Lower Waikato, *H. Carse!* Lake Whangape, *T. F. C.;* East Cape district, *Bishop Williams!* Hawke's Bay—*Colenso!* Wellington—Wairarapa, *Buchanan!* near Wellington, *T. Kirk!* South Island: Not uncommon in marshy places throughout. Sea-level to 3500 ft. *Marsh Foxtail.*

An abundant grass in marshy places in most temperate regions. The allied species *A. pratensis* (Meadow Foxtail) and *A. agrestis* (Slender Foxtail), descriptions of which will be found in any British Flora, have become naturalized in several localities in both Islands.

15. **SOROBOLUS** R. Br. 1810

Annual or perennial grasses, of very various habit. Leaves flat or convolute. Spikelets small, often minute, 1-flowered, awnless, arranged in a narrow spike-like or effuse panicle; rhachilla very short, obscurely jointed above the 2 outer glumes, not produced beyond the flower or very rarely so. Glumes 3, membranous, nerveless or 1–3-nerved; 2 outer unequal, empty, persistent or separately deciduous; 3rd or flowering glume longer than or equalling the 2nd. Palea usually almost as long as the flowering glume, 2-nerved, often splitting between the nerves. Lodicules 2, small. Stamens 2–3. Styles short, distinct. Grain free within the flowering glume and palea; the pericarp lax, usually deciduous.

Species about 80, dispersed through the tropical and subtropical regions of both mispheres, but most numerous in America.

Ex. 1. **S. indicus** *R. Br. Prodr.* (1810) 170.—Perennial. Culms tufted, stout, rigid, perfectly glabrous, 1–2 ft. high. Leaves mostly at the base of the culms and shorter than them, 4–12 in. long, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, usually

S. capensis Kunth. Enum. Pl. i: 212: 1833
see N.Z. Journ. Sc. & Tech. 15: 1934: 255

involute, tapering to a fine point, glabrous, margins smooth; sheaths pale, compressed, often ciliate on the margins; ligules reduced to a ciliate rim. Panicle erect, spike-like, very narrow, 3–9 in. long, sometimes interrupted below; branches short, crowded, erect and appressed to the rhachis. Spikelets very numerous, crowded, $\frac{1}{2}$ in. long. Two outer glumes unequal, the lowest not much more than $\frac{1}{2}$ the length of the 2nd, hyaline, nerveless, or the 2nd 1-nerved; 3rd or flowering glume nearly twice as long as the 2nd, oblong-lanceolate, acute, 1–3-nerved. Palea almost as long as the flowering glume. Stamens usually 2. Grain obovoid or roughly quadrangular, reddish; pericarp thin.—*Benth. Fl. Austral.* vii (1878) 622; *Cheesem. Man. N.Z. Fl.* (1906) 860. S. elongatus *R. Br. Prodr.* (1810) 170; *Hook. f. Fl. Nov. Zel.* i (1853) 295; *Handb. N.Z. Fl.* (1864) 327; *Buch. N.Z. Grasses* (1879) t. 18.

North and South Islands: Lowland districts from the North Cape to Nelson and Marlborough, abundant, especially in the northern part of the North Island. *Ratstail.*

A common grass in all warm countries. Although now presenting all the appearance of a true native, it is certainly introduced into New Zealand. Bishop Williams informs me that it made its first appearance at the Bay of Islands in 1840, shortly after the arrival of a ship called the "Surabayo," which, while on a voyage from Valparaiso to Sydney, laden with horses and forage, put into the Bay of Islands in a disabled state, and was there condemned and her cargo sold. *Erigeron canadensis* and other weeds appeared at the same time.

16. **SIMPLICIA** T. Kirk.

A slender decumbent grass. Leaves flat. Spikelets minute, 1-flowered, solitary and pedicelled on the branches of a slender panicle; rhachilla disarticulating above the 2 outer glumes, produced above the flower into a minute bristle. Glumes 3; 2 outer minute, unequal, empty, hyaline, persistent; 3rd or flowering glume much longer than the outer glumes, oblong-lanceolate, acuminate or shortly awned, keeled, obscurely 1–3-nerved. Palea almost as long as the flowering glume, 2-nerved. Lodicules 2. Stamens 1–3. Styles distinct; stigmas shortly plumose. Grain oblong, free within the flowering glume and palea.

A peculiar monotypic genus, endemic in New Zealand. Professor Hackel considers it to be intermediate between *Sporobolus* and *Agrostis*, differing from the former in the rhachilla being produced beyond the flower, and from the latter in the minute unequal empty glumes, large palea, &c. Mr. Kirk compared it to *Muhlenbergia*. For its original discovery we are indebted to the exertions of Mr. Petrie.

1. **S. laxa** *T. Kirk in Trans. N.Z. Inst.* xxix (1897) 497.—Culms weak, decumbent, very slender, filiform, 8–18 in. long. Leaves 1–4 in. long by $\frac{1}{20}$–$\frac{1}{8}$ in. broad, flat, flaccid, glabrous or minutely ciliate along the nerves; sheaths long, glabrous or pubescent; ligule long, membranous. Panicle very slender, narrow, 2–6 in. long; rhachis filiform; branches few, filiform, erect, smooth or minutely scaberulous. Spikelets lanceolate, pale-green, about $\frac{1}{12}$ in. long. Two outer glumes minute, unequal, glabrous, the lower $\frac{2}{3}$ he length of the upper, which is $\frac{1}{4}$ the length of the flowering glume; 3rd or flowering glume acuminate or shortly awned, pubescent with short stiff erect hairs. Palea almost as long as the flowering glume, acute, pubescent. Ripe grain not seen.—*Cheesem. Man. N.Z. Fl.* (1906) 861; *Ill. N.Z. Fl.* (1914) t. 221.

North Island: Wellington—Dry River, Ruamahanga, Lower Wairarapa, *T. Kirk!* South Island: Otago—Deep Stream, Waikouaiti, *Petrie!*

Zotov: Trans 73: 36. places Poa uniflora Buch. as var. buchananii of Simplicia laxa Muhlenb. 1817: 151.

17. **AGROSTIS** Linn. 1735

Annual or perennial grasses, of very various habit. Leaves usually flat, sometimes setaceous, often flaccid; ligules membranous. Spikelets small, 1-flowered, arranged in effuse or contracted panicles with capillary whorled branches; rhachilla disarticulating above the 2 outer glumes, not produced beyond the flower. Glumes 3; 2 outer equal or subequal, empty, keeled, acute, not awned, usually 1-nerved; 3rd or flowering glume membranous or hyaline, glabrous or hairy, usually truncate, 5-nerved or rarely 3-nerved, with a dorsal awn or unawned, callus glabrous or with a few minute hairs. Palea usually short, often minute or wanting, thin and delicate, hyaline, 2-nerved or nerveless. Lodicules 2. Stamens 3. Styles very short, distinct; stigmas plumose. Grain oblong, free within the flowering glume.

Species about 125, found in all parts of the world, but most abundant in temperate regions, and penetrating as far into the Arctic and Antarctic Zones as any other grasses. Of the 7 species admitted in this work, one is generally distributed in high southern latitudes, two or possibly three are found in Australia, the remainder are endemic.

* Awn of flowering glume distinctly exserted beyond the empty glumes.

Culms 3–18 in. Panicle contracted, 1–4 in. Spikelets $\frac{1}{6}$ in. long; pedicels almost hispid .. .. 1. *A. magellanica.*

** Awn of flowering glume often wanting: when present not exceeding the empty glumes.

Minute, softly pulvinate, seldom more than 1 in. high. Panicle usually sunk among the leaves .. .. 2. *A. muscosa.*

Slender, strict, usually 1-noded, 2–9 in. Panicle narrow, spike-like; spikelets usually purplish .. .. 3. *A. subulata.*

Slender, not so strict, 3-noded, 3–6 in. Panicle more open. Spikelets straw-coloured .. .. 4. *A. pallescens.*

Tufted, 4–18 in.; innovation-shoots intravaginal, without leafless scales at the base. Panicle 2–5 in., contracted, rather dense; branches numerous. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in., empty glumes scabrid on the keel .. .. 5. *A. Dyeri.*

Laxly tufted, 6–18 in.; innovation-shoots extravaginal, with leafless scales at the base. Panicle 2–6 in., lax; branches in whorls of 3–5. Spikelets $\frac{1}{8}$ in., empty glumes smooth .. .. .. 6. *A. Petriei.*

Weak, very slender, 6–18 in. Panicle 2–6 in., lax and spreading; branches few, capillary, trichotomously divided. Spikelets minute, $\frac{1}{15}$ in. .. .. 7. *A. parviflora.*

Laxly tufted, very slender, 6–15 in. Panicle linear, $1\frac{1}{2}$–4 in. by $\frac{1}{10}$–$\frac{1}{6}$ in.; branches short, erect. Spikelets $\frac{1}{12}$–$\frac{1}{10}$ in., pale, shining .. .. 8. *A. tenella.*

Two common European species, *A. vulgaris* (Red-top) and *A. alba* (Fiorin), are copiously naturalized in most parts of the Dominion. They come nearer to *A. Dyeri* than to any other of the indigenous species, but differ in the creeping rootstocks, laxer panicles, and in the florets having a well-developed palea. Descriptions of them will be found in any British Flora.

1. **A. magellanica** *Lam. Ill.* i (1791) 160.—Culms tufted, very variable in size, 3–18 in. high, erect or shortly decumbent at the base, stout or slender, quite glabrous, leafy. Leaves numerous, shorter than the culms, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, involute, striate, scaberulous on the margins and veins; sheaths long, contracted at the mouth, deeply grooved, pale; ligules oblong, membranous, truncate at the apex, lacerate. Panicle 1–4 in. long, $\frac{1}{4}$–$\frac{3}{4}$ in. broad, contracted, linear-oblong, rather dense, erect or inclined; rhachis stout, scabrid; branches numerous, whorled, erect, scaberulous. Spikelets $\frac{1}{6}$ in. long, light-green or purplish; pedicels usually shorter than the

See Fl. Ant. 1944: 96. A. auckl.
Fl. N.Z. 1853: 296. A. parv. var. perpus.

spikelets, scabrid, thickened at the tips. Two outer glumes subequal, lanceolate, acuminate, ciliate or almost hispid along the keel, sides scaberulous; 3rd or flowering glume ½ the length of the 2nd or rather shorter, membranous, glabrous, truncate at the apex and more or less evidently 4-cuspidate, awn from half-way down the back, straight or flexuous or slightly recurved, usually longer than the spikelet. Palea very short, hardly exceeding the ovary, sometimes wanting.—*Hook. f. Phil. Trans. Roy. Soc.* (1879) 21; *Cheesem. Man. N.Z. Fl.* (1906) 862; *Petrie in Subantarct. Is.* ii (1909) 473. A. antarctica *Hook. f. Fl. Antarct.* ii (1847) 374, t. 132; *Handb. N.Z. Fl.* (1864) 327. A. multicaulis *Hook. f. Fl. Antarct.* i (1844) 95. See Petrie Trans 25: 275

South Island: Otago—Head of Clinton Valley, near Lake Te Anau, *Petrie!* Auckland and Campbell Islands: *Sir J. D. Hooker, T. Kirk! Cockayne! W. R. Chambers!* Antipodes Island: *T. Kirk.* Macquarie Island: Abundant, *A. Hamilton, H. Hamilton.*

Also found in Chile, Fuegia, the Falkland Islands, Kerguelen Island, Marion and Heard Islands. Sir J. D. Hooker, in his memoir on the flora of Kerguelen Island (Phil. Trans. vol. clxviii) has reduced both *A. antarctica* and *A. multicaulis* to *A. magellanica* Lam. Professor Hackel concurs in this, remarking that *A. antarctica* only differs from the typical *A. magellanica* in the less-pointed outer glumes, and that *A. multicaulis* is only a dwarfed state, not separable as a distinct variety.

2. **A. muscosa** *T. Kirk in Trans. N.Z. Inst.* xiii (1881) 385.—Minute, very densely tufted, forming small rounded cushion-like patches 1–2 in. diam., and less than 1 in. high. Culms densely packed, much branched at the base, leafy throughout. Leaves longer or shorter than the culms, pale glaucous-green; blades spreading, flaccid, involute, almost capillary; sheaths shorter or longer than the blades, lax, whitish, membranous, grooved; ligules long, subulate. Panicle very short and dense, often concealed among the leaves, contracted into a close rounded head ⅛–⅙ in. diam., usually many-spiculate, but in depauperated states the spikelets may be reduced to 2–6, or in large states the panicle may be lengthened to ¼–⅓ in.; branches short, sparsely hairy. Spikelets about $\frac{1}{12}$ in. long, pale-green. Two outer glumes subequal, ovate-lanceolate, acute, with a green scabrid keel and thin hyaline margins; 3rd or flowering glume about ¼ shorter, ovate-oblong, truncate, 5-nerved, awn wanting. Palea wanting. Grain broadly oblong.—*Cheesem. Man. N.Z. Fl.* (1906) 863. A. Spencei *T. Kirk in Trans. N.Z. Inst.* xxix (1897) 539 (*name only*). A. aemula *var.* spathacea *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 32, t. 7, f. 41–47.

North Island: Omatangi, Lake Taupo, *S. Berggren!* Mount Egmont, *T. F. C.*; Waimarino Plateau and slopes of Tongariro, *T. F. C.*; Lake Rotoaira, *T. Kirk, T. F. C.*; Mount Holdsworth, *W. C.*; Tarndale, *Cockayne* and *Foweraker.* Marlborough—Awatere Valley, *Cockayne.* Canterbury—Broken River basin, *J. D. Enys, T. Kirk, T. F. C.*; Mackenzie Plains, *T. F. C.* Otago—Not uncommon in the eastern and southern portions of the province, *Petrie! T. Kirk!* Altitudinal range usually from 1500 to 4500 ft., but descending to sea-level in Southland.

B.M. D'Urville Island 1941 Ashburton Trans 57: 69.

3. **A. subulata** *Hook. f. Fl. Antarct.* i (1853) 95, t. 53.—Culms compactly tufted, slender, strict, erect, smooth, 1–2-noded, the nodes near the base of the culm, 2–9 in. high. Leaves crowded near the base of the culms and usually much shorter than them, very narrow, often filiform, strict, erect, involute, smooth and glabrous; sheaths long, grooved, glabrous; ligules scarious, narrow-oblong. Panicle very narrow, almost spike-like, ½–2 in. long, erect, purplish or pale-green; rhachis smooth or obscurely

scabrid ; branches in fascicles of 2-5, unequal, short, erect, capillary, scabrid. Spikelets about $\frac{1}{10}$ in. long. Two outer glumes slightly unequal, oblong-lanceolate, acute, green or purplish, usually scabrid or ciliate on the keel, but sometimes glabrous, margins thin and hyaline ; 3rd or flowering glume about $\frac{1}{3}$ shorter, thin and membranous, truncate, minutely denticulate, smooth, faintly 5-nerved, awn usually absent but sometimes present from the middle of the back. Palea wanting. Grain oblong.—A. Muelleri *Benth. Fl. Austral.* vii (1878) 576 ; *Cheesem. Man. N.Z. Fl.* (1906) 864. A gelida *F. Muell. in Trans. Vict. Inst.* (1855) 43 (*not of Trin.*). A. canina *var. Hook. f. Handb. N.Z. Fl.* (1864) 328 ; *Buch. N.Z. Grasses* (1879) t. 20, f. A. see Petrie Sub. Is. 2 : 4-73

North Island.—Tongariro and Ruapehu, *T. F. C., Cockayne ;* Ruahine Mountains, *Colenso, A. Hamilton ;* Tararua Mountains, *B. C. Aston !* Mount Hector, *Petrie.* South Island : Common at high altitudes along the central chain of mountains throughout. Auckland and Campbell Islands : *Hooker ! T. Kirk, F. R. Chapman.*

Very closely allied to *A. Dyeri*, and mainly distinguished by its much smaller size, narrower panicle, and different habit. The stems are generally 1-noded, whereas they are usually 2–3-noded in *A. Dyeri*. I agree with Mr. Petrie in considering that it is identical with Hooker's *A. subulata*, originally described from immature specimens collected on Campbell Island.

4. **A. pallescens** *Cheesem. in Trans. N.Z. Inst.* liii (1921) 423.—Annual, densely tufted and often forming a close sward, pale straw-coloured. Culms 3–6 in. high, slender, smooth, erect, 3-noded, the uppermost node high up the culm. Leaves numerous towards the base of the culms and shorter than them, very narrow, almost filiform, smooth or very minutely scabrid, erect or somewhat spreading ; sheaths long, deeply grooved ; ligule thin, scarious. Panicle narrow, but not so much so as *A. subulata*, lanceolate or ovate-lanceolate, $\frac{1}{2}$–1 in. long, straw-coloured ; branches in fascicles of 2–4, unequal in length, somewhat spreading, finely scabrid. Spikelets $\frac{1}{12}$–$\frac{1}{10}$ in. long. Two outer glumes slightly unequal, oblong-lanceolate, subacute, membranous, scabrid on the keel ; margins thin ; 3rd or flowering glume about $\frac{1}{3}$ shorter, thin and membranous, hyaline, truncate, faintly 5-nerved ; awn wanting. Palea wanting. Grain oblong.—A. Muelleri *var.* paludosa *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 864.

South Island : Swamps near Broken River, *T. Kirk !* swamps in Tasman Valley, not uncommon, *T. F. C.* 1500–2500 ft.

Near to *A. subulata*, but amply distinct in its 3-noded culms, the upper node of which is sometimes situated quite $\frac{1}{3}$ of the way up the culm, in the straw-coloured spikelets, and in the broader and more open panicles. In *A. subulata* the culms are seldom more than 1-noded, the node being placed near the base of the culm, the panicles are narrow and spike-like, and usually purplish in colour. In addition to the above, *A. subulata* is always found on the steep rocky slopes of mountains, never in swamps. 71 (1941) 83.

5. **A. Dyeri** *Petrie in Trans. N.Z. Inst.* xxii (1890) 441.—Perennial ; innovation-shoots intravaginal, not clothed at the base with leafless scales. Culms tufted, 4–18 in. high, slender, erect or geniculate at the base, glabrous, 2–3-noded, the upper node considerably below the culm. Leaves shorter than the culms, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, flat or convolute when dry, striate, scaberulous on the margins and both surfaces ; sheaths terete, grooved, glabrous, the upper long ; ligules oblong, obtuse, membranous, lacerate. Panicle elongated, usually from 2 to 5 in. long, but shorter in depauperated forms, erect, usually more or less contracted, rarely open, green or brownish-green ; rhachis slender, scaberulous above ; branches in rather

distant fascicles placed alternately on opposite sides of the rhachis, strict, erect, capillary, scaberulous, simple or branched from the base or above; pedicles longer or shorter than the spikelets. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in. long. Two outer glumes subequal, lanceolate, acute, 1–3-nerved, scabrid on the keel; 3rd or flowering glume about $\frac{1}{3}$ shorter than the 2nd, oblong, truncate, minutely 4-toothed, awnless. Palea wanting. Anthers small.—*Cheesem. Man. N.Z. Fl.* (1906) 864; *Ill. N.Z. Fl.* ii (1914) t. 222. A. canina *Hook. f. Fl. Nov. Zel.* i (1853) 296; *Handb. N.Z. Fl.* (1864) 328; *Buch. N.Z. Grasses* (1879) t. 19 (*not of Linn.*). A. parviflora *Buch. N.Z. Grasses* (1879) t. 20c (*not of R. Br.*).

Var. **aristata** *Hack. MS.*—Flowering glume awned. Other characters as in the type.

Var. **delicatior** *Hack. MS.*—More slender. Panicle broader, much more lax. Spikelets $\frac{1}{3}$ smaller. Flowering glume awned.

North and South Islands: Mountain districts from the East Cape, Taupo, and Mount Egmont southwards, abundant. Stewart Island: Not uncommon, *Cockayne.* 1000–5000 ft.

Closely allied to the northern *A. canina* Linn., to which it was originally referred by Sir J. D. Hooker. But it differs from all the forms of *A. canina*, as has been pointed out by Professor Hackel, in the innovation-shoots being always intravaginal, in the more scabrid leaves, in the narrower and more contracted panicles, and in the rather larger spikelets. It usually constitutes a large proportion of the alpine pastures in elevated districts in both Islands.

6. **A. Petriei** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 379.—Perennial; innovation-shoots extravaginal, clothed at the base with leafless scales gradually increasing in size. Clums tufted, slender, erect, 6–18 in. high, glabrous, 3–5-noded, upper node almost at the middle of the culm. Leaves 2–5 in. long, $\frac{1}{15}$–$\frac{1}{12}$ in. broad, linear, acute, flat or convolute when dry, glaucous, scabrid on the margins and both surfaces; sheaths terete, glabrous; ligules long, oblong, obtuse, denticulate. Panicle 2–6 in. long, oblong, open, lax-flowered; rhachis smooth; branches in whorls of 3–5, capillary, scaberulous, again branched; pedicels hardly thickened at the tips, about equal in length to the spikelets. Spikelets linear-lanceolate, $\frac{1}{8}$ in. long, pale-green. Two outer glumes equal, lanceolate, acute, I-nerved, smooth; 3rd or flowering glume $\frac{1}{4}$ shorter, thin and membranous, obtuse, minutely denticulate, 5-nerved; awn from the middle of the back, straight, about as long as the empty glumes, rarely wanting, callus set with short hairs. Palea wanting. Anthers large.—*Cheesem. Man. N.Z. Fl.* (1906) 865.

Var. **mutica** *Hack. MS.*—Awn wanting.

South Island: Otago—Cromwell, Nevis Valley, Dunstan Mountains, *Petrie!* Lake Wakatipu, *T. Kirk!* 1000–2500 ft.

According to Professor Hackel this is nearest to *A. canina*, which differs in its bright-green smooth leaves, much more compound and closer panicle, smaller spikelets, in the scabrid keel of the empty glumes, and small anthers. *A. Dyeri* is separated by the innovation-shoots being intravaginal and not clothed with leafless scales, to say nothing of the broader leaves, dense panicle, and spikelets with the empty glumes scabrid on the keel.

7. **A. parviflora** *R. Br. Prodr.* (1810) 170.—Culms laxly tufted, very slender, weak, often decumbent or prostrate at the base, erect or ascending above, quite smooth, 6–18 in. long. Leaves chiefly towards the base of the culms, the lowermost soon withering, 2–6 in. long, usually narrow and often almost filiform, but in luxuriant specimens broader and sometimes

$\frac{1}{12}$–$\frac{1}{10}$ in. diam., flaccid, flat or involute, smooth or the margins minutely scabrid; sheaths long, grooved, quite smooth; ligules long, membranous, lacerate. Panicle varying in length from 2 to 6 in. or more, compound, very lax and slender, drooping; primary branches long, capillary, scaberulous, erect at first but soon spreading, trichotomously divided, lowermost in clusters of 4–6, upper in distant pairs; secondary branches from above the middle, again divided; pedicels thickened at the tips. Spikelets very minute, about $\frac{1}{15}$ in. long, shining, pale-green, sometimes tinged with purple. Two outer glumes slightly unequal, lanceolate, acute, membranous, slightly scabrid on the keel, margins hyaline; 3rd or flowering glume about $\frac{1}{4}$ shorter, broad, truncate, hyaline, delicately 5-nerved, awnless. Palea wanting.—*Hook. f. Fl. Nov. Zel.* i (1853) 296; *Handb. N.Z. Fl.* (1864) 328; *Cheesem. Man. N.Z. Fl.* (1906) 866. A. scabra *Benth. Fl. Austral.* vii (1878) 576 (*not of Willd.*).

North Island: Inland Patea and shores of Cook Strait, *Colenso!* South Island: Pelorus Valley, *J. H. Macmahon!* near Westport, *W. Townson!* near Dunedin, *Petrie!*

Since the publication of the first edition of this work I have obtained no fresh information respecting this plant, which can be recognized without much difficulty by the weak habit, very slender lax spreading panicle, and minute spikelets, which are smaller than those of any other New Zealand species. It was originally referred to *A. parviflora* by Hooker in the Flora, but does not quite match the plate of that species given in the "Flora Tasmanica" (t. 158), nor any Australian specimens that I have seen. Bentham referred the Australian plant to *A. scabra* Willd., a North American species; but that is a larger and more erect plant, with a more copiously divided panicle, and with narrower spikelets, much more scabrid on the keel. Professor Hackel, who has examined my specimens, says, "Not easy to name. Surely not *A. scabra* Willd., but very near the North American *A. perennans* Tuck. It is most probably *A. parviflora* R. Br., but without seeing one of Brown's types I cannot be quite sure of the identity." It should be mentioned that most of the specimens referred to *A. parviflora* by New Zealand botanists are nothing but small states of *A. Dyeri* Petrie (the *A. canina* of the Handbook), as, for instance, the plant figured as *A. parviflora* by Buchanan in his New Zealand Grasses, t. 20c. All such specimens can be at once distinguished by the strict habit, contracted panicle, and larger spikelets.

8. **A. tenella** *Petrie in Trans. N.Z. Inst.* xxii (1890) 442.—Apparently annual. Culms laxly tufted, erect, very slender, quite smooth and glabrous, 3–4-noded, 6–15 in. high. Leaves few, much shorter than the culms, erect, very narrow, filiform or setaceous, involute, finely striate; sheaths rather long, close, smooth; ligules oblong, obtuse, lacerate. Panicle very long and narrow, 1½–4 in. by $\frac{1}{10}$–$\frac{1}{6}$ in. broad, erect, pale-green; rhachis minutely scaberulous; branches few, fascicled, very short, erect; pedicels short, capillary, scaberulous. Spikelets $\frac{1}{12}$–$\frac{1}{10}$ in. long, pale. Two outer glumes subequal, lanceolate, acute, shining, 1-nerved, slightly scabrid on the keel, smooth on the sides; 3rd or flowering glume about $\frac{1}{4}$ shorter, ovate-lanceolate, thin and hyaline, truncate, minutely denticulate, glabrous, faintly 5-nerved, awn wanting. Grain oblong.—*Cheesem. Man. N.Z. Fl.* (1906) 866.

South Island: Canterbury—Broken River, *Petrie!* Porter River, *T. Kirk!* Otago—Macrae's, Lake Wakatipu, *Petrie!* 1000–3000 ft.

A very distinct species, easily recognized by the very slender habit, excessively narrow pale-green panicle, and small shining spikelets.

18. **DEYEUXIA** Clarion.

Annual or perennial grasses. Leaves flat or involute; ligules membranous. Spikelets small, 1-flowered, arranged in effuse or contracted or spike-like panicles with capillary whorled branches; rhachilla disarticulating above the 2 outer glumes, produced beyond the flower into a silky

bristle. Glumes 3; 2 outer equal or subequal, persistent, empty, keeled, acute, not awned, usually 1-nerved; 3rd or flowering glume shorter than the empty glumes or equalling them, thin and hyaline or rigidly membranous or almost coriaceous, 5-nerved, entire or 2–4-dentate, callus at the base silky; awn generally present, straight or twisted, inserted above or below the middle of the glume. Palea more than half as long as the flowering glume or almost equalling it, thin, 2–nerved or 2-keeled. Stamens 3. Styles distinct, short; stigmas plumose. Grain oblong or obovoid, enclosed within the flowering glume and palea.

Species over 100, widely dispersed throughout the temperate regions of both hemispheres, particularly abundant in Andine South America. It is not at all easy to separate *Deyeuxia* from the allied genera *Agrostis* and *Calamagrostis*, and of late many authors, including Hackel, have placed the majority of the species under the latter genus. But it has always appeared to me that for taxonomic purposes it is desirable to have a genus intercalated between the typical species of *Agrostis* on the one side and *Calamagrostis* on the other. In the first edition of this work I therefore followed the arrangement proposed in Hooker's "Flora of British India" (vol. vii, p. 253), where *Agrostis* is limited to species in which the rhachilla is not produced at the back of the flower, and in which the callus of the flowering glume is naked or nearly so, *Calamagrostis* containing those in which there is also no prolongation of the rhachilla, but which have the callus villous with long hairs, while in *Deyeuxia* the species have both an elongated rhachilla and hairy callus. Further study has convinced me that this course is much to be preferred, particularly as there are no genuine species of *Calamagrostis* in New Zealand as originally limited. As defined above, there are 7 New Zealand species of the genus, 3 of which extend to Australia and Tasmania, the remaining 4 being endemic.

* Flowering glume $\frac{1}{3}$–$\frac{1}{2}$ shorter than the empty glumes, thin and hyaline. Panicle very broad and lax; branches long, spreading, capillary.

Spikelets $\frac{1}{12}$–$\frac{1}{8}$ in. Flowering glume silky, truncate, minutely 4-denticulate; awn from the middle of the back	1. *D. Forsteri.*
Spikelets $\frac{1}{12}$–$\frac{1}{10}$ in. Flowering glume quite glabrous. Awn short	2. *D. glabra.*
Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. Flowering glume silky at the base only, 2 lateral nerves produced into short awns, dorsal awn from below the middle of the back	3. *D. Billardieri.*

** Flowering glume not much shorter than the empty glumes, rigidly membranous. Panicle narrow, contracted.

Slender, 4–12 in. Leaves filiform. Panicle 1–2½ in. Spikelets $\frac{1}{8}$ in. long; callus-hairs very long	4. *D. setifolia.*
Slender, 9–36 in. Leaves narrow, involute. Panicle 2–5 in. Spikelets $\frac{1}{6}$–$\frac{1}{4}$ in.; awn from below the middle, exserted; callus-hairs short. Rhachilla obviously produced	5. *D. avenoides.*
Tall, slender, 2–4 ft. Leaves flat, $\frac{1}{6}$–$\frac{1}{4}$ in. broad. Panicle 4–6 in. Spikelets $\frac{1}{6}$–$\frac{1}{4}$ in.; awn short, almost terminal. Rhachilla obviously produced	6. *D. Youngii.*
Tall, stout or slender, 1–3 ft. Leaves flat or involute. Panicle 2–6 in. Spikelets $\frac{1}{8}$ in.; flowering glume 4-cuspidate; awn from near the base. Rhachilla not produced or very obscurely so	7. *D. quadriseta.*

D. fil: formis (Forst. f.) Hook. f. 1817: 266.

1. **D. Forsteri** *Kunth Rev. Gram.* i (1829) 77.—Annual or rarely perennial, very variable in size and habit. Culms tufted, erect or decumbent at the base, slender, smooth, 2–4-noded, 6–24 in. high. Leaves shorter than the culms, very narrow and involute or broader and flat, $\frac{1}{12}$–$\frac{1}{6}$ in. diam., almost glabrous or scaberulous on the margins and principal veins; sheaths smooth, grooved, the uppermost usually long; ligules long, narrow, membranous. Panicle 3–12 in. long, usually very lax and spreading when mature, but contracted in the young state; branches in distant whorls or clusters, the lowermost 2–6 in. long or more, repeatedly trichotomously divided, finely capillary, scabrid; pedicels very slender. Spikelets numerous,

pale-green, $\frac{1}{12}$–$\frac{1}{8}$ in. long. Two outer glumes subequal, lanceolate, acuminate, membranous, 1-nerved, keel scabrid; 3rd or flowering glume $\frac{1}{3}$–$\frac{1}{2}$ shorter, oblong, truncate, minutely 4-denticulate, hyaline, more or less silky on the sides and with a tuft of hairs at the base; awn from the middle of the back, slender, straight or bent. Palea narrow-linear, bifid at the apex. Rhachilla usually produced behind the palea as a short silky bristle, but often very small and hardly perceptible.—*Hook. f. Fl. Nov. Zel.* i (1853) 298; *Benth. Fl. Austral.* vii (1878) 579; *Buch. N.Z. Grasses* (1880) t. 21; *Cheesem. Man. N.Z. Fl.* (1906) 868. Avena filiformis *Forst. f. Prodr.* (1786) n. 46. Agrostis avenacea *Gmel. Syst.* i (1791) 171. A. Forsteri *Roem. and Schult. Syst.* ii (1817) 359; *A. Rich. Fl. Nouv. Zel.* (1832) 131; *A. Cunn. Precur.* (1836) n. 253; *Raoul Choix* (1846) 39. A. aemula *R. Br. Prodr.* (1810) 172; *Hook. f. Handb. N.Z. Fl.* (1864) 329; *Buch. N.Z. Grasses* (1879) t. 21. A. Solandri *F. Muell. Veg. Chat. Is.* (1864) 60. see Petrie Trans 49: 55 also Sub Is. 2:474. Skottsb. Småins Medd Gtanden 163 s Veg. Easter Is

North and South Islands, Stewart Island, Chatham Islands, Subantarctic Islands: Abundant throughout, from sea-level to 4000 ft. Easter Id.

Var. **pilosa** *Cheesem.*—Coarser and more robust. Leaves broader, $\frac{1}{4}$–$\frac{1}{3}$ in. or even more, flat. Spikelets slightly larger.—D. pilosa *Buch. N.Z. Grasses* (1880) 6. Agrostis pilosa *A. Rich. Fl. Nouv. Zel.* (1832) 134, t. 23; *Raoul Choix* (1846) 39; *Hook. f. Fl. Nov. Zel.* i (1853) 297; *Handb. N.Z. Fl.* (1864) 329; *Buch. N.Z. Grasses* (1879) t. 22.

North and South Islands: Damp subalpine localities, not uncommon. Hardly more than a luxuriant state of the type.

Var. **semiglabra** *Hack. MS.*—Flowering glume glabrous on the back, its callus sparingly pilose. Otherwise as in the type.

North and South Islands: Not uncommon.

Var. **humilior** *Hack. MS.*—Root often perennial. Culms 3–10 in. high. Panicle very broad and spreading; branches few, distant, binate, few-flowered.—A. striata *Col. in Trans. N.Z. Inst.* xxi (1889) 107.

North and South Islands: Probably not uncommon in mountain districts, Lake Waikaremoana, *Hill!* Clarence Valley, Lake Tennyson, Broken River, Tasman Valley, &c., *T. F. C.*; Lake Te Anau, *Petrie!*

Var. **littoralis** *Hack. MS.*—Root annual. Culms 2–9 in., often forming a compact sward. Panicle rather narrow, contracted, many-flowered. Empty glumes linear-lanceolate, narrower than in the type.

Kermadec Islands, North and South Islands: Rocky or gravelly places near the sea, not uncommon.

Var. **Lyallii** *Hack. MS.*—Culms 6–12 in. Leaves narrow, involute. Panicle lax; branches few, binate or ternate. Spikelets larger, $\frac{1}{3}$–$\frac{1}{2}$ in. long. Flowering glume densely clothed with silky hairs.—A. Lyallii *Hook. f. Fl. Nov. Zel.* i (1853) 297.

South Island: Near Westport, *W. Townson!* Okarito, *A. Hamilton!* Jackson's Bay, *T. Kirk!* Milford Sound, *Lyall, T. Kirk!* Catlin's River, *Petrie!* Auckland Islands: *T. Kirk!*

Var. **micrathera** *Hack. MS.*—Habit of var. *Lyallii*, but larger and leaves broader. Spikelets still larger, $\frac{1}{3}$–$\frac{1}{2}$ in. long. Empty glumes linear-lanceolate, acuminate. Flowering glume short, $\frac{1}{3}$ as long as the empty glumes, very thin, sparingly silky; awn from above the middle, short, delicate, hardly exserted beyond the empty glumes.

Antipodes Island, Campbell Island: *T. Kirk!* Possibly the same as *Agrostis leptostachya* Hook. f. Fl. Antarct. i (1844) 94, but I have not seen an authenticated specimen, and it is described as having no palea and a long awn.

D. Forsteri is one of the most generally diffused plants in New Zealand, and is certainly one of the most variable. In attempting to characterize its chief forms I have mainly followed the grouping suggested to me by Professor Hackel, who has kindly examined sets of all the varieties contained in my herbarium. The species is as plentiful in Australia and Tasmania as in New Zealand. As the earliest name of this plant is undoubtedly Forster's *Avena filiformis*, Dr. Cockayne, in his florula of Stewart Island (p. 49), has changed the specific name to *filiformis*. But this is inadmissible, as a valid earlier name of *filiformis* has already been used in both *Calamagrostis* and *Deyeuxia*. (*Calamagrostis filiformis* Griseb. in Goett. Nachr. (1868) 78; *Deyeuxia filiformis* Hook. f. Fl. British India, vii (1897) 268.)

2. **D. glabra** *Petrie in Trans. N.Z. Inst.* xlvi (1914) 36.—Smooth, slender, laxly tufted, sparingly branched from the base. Culms 6–12 in. long, slender, weak, sparingly leafy. Leaves remote, the upper ones the longest, the lower gradually reduced in size; smooth, flat, striate, bright-green. Sheaths long, grooved; ligules long, narrow, membranous, lacerate at the tip. Panicle usually lax and spreading when mature, contracted in the young state; branches in distant whorls or clusters, finely capillary, minutely scaberulous. Spikelets few, on very slender pedicels, small, $\frac{1}{12}$–$\frac{1}{10}$ in. long, pale-green. Two outer glumes subequal, lanceolate, acute, membranous, faintly 1-nerved, finely scabrid or ciliate on the keel; 3rd or flowering glume $\frac{1}{3}$–$\frac{1}{2}$ shorter, oblong, truncate and denticulate at the tip, quite glabrous, membranous, faintly 3-nerved; awn short, slender, barely equalling the tip of the outer glumes. Palea narrow-linear, bifid at the apex. Rhachilla short, sparingly pilose.

South Island: Moist places near the sea at Bluff and Fortrose, Southland, *Petrie!*

Mr. Petrie states that this can be "readily distinguished from *D. Forsteri* by the glabrous flowering glumes, the short delicate awn, and the absence of a tuft of hairs at the base of the flowering glume." But I think there can be little doubt that it is only a variety of *D. Forsteri* in which the hairs at the base of the flowering glume are absent. There are no other points of difference of any importance, and it is well known that the hairs on the flowering glume of *Deyeuxia* form a very variable character.

3. **D. Billardieri** *Kunth Rev. Gram.* i (1829) 77.—Culms tufted, usually rather stout, erect or decumbent at the base, 9–18 in. high, leafy throughout. Leaves shorter than the culms, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, flat, striate, usually scabrid on the margins and veins; sheaths rather narrow, rough, the uppermost very long, usually enclosing the culm up to the base of the panicle; ligules long, membranous, lacerate. Panicle 4–12 in. long, very broad and lax, often as broad as long when fully expanded; branches numerous, in regular whorls, long, capillary, scabrid, trichotomously divided; pedicels thickened at the tips. Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. long, green or purplish. Two outer glumes slightly unequal, narrow-lanceolate, acuminate, 1-nerved or 3-nerved with the lateral veins very short, scabrid on the keel and sides; 3rd or flowering glume $\frac{1}{4}$–$\frac{1}{3}$ shorter, oblong, truncate, silky at the base, 5-nerved, the 2 lateral nerves produced on each side into short awns, the 2 outer of which are longer than the 2 inner; dorsal awn from below the middle, straight or bent, usually exceeding the spikelet. Palea about $\frac{2}{3}$ as long as the flowering glume, linear, 2-nerved. Rhachilla produced into a silky bristle almost as long as the palea.—*Hook. f. Fl. Nov. Zel.* i (1853) 298; *Benth. Fl. Austral.* vii (1878) 580; *Buch. N.Z. Grasses* (1880) 6; *Cheesem. Man. N.Z. Fl.* (1906) 869; *Ill. N.Z. Fl.* ii (1914) t. 223. Agrostis Billardieri *R. Br. Prodr.* (1810) 171; *A. Rich. Fl. Nouv. Zel.* (1832) 130; *A. Cunn. Precur.* (1836) n. 252; *Raoul Choix* (1846) 39; *Hook. f. Handb. N.Z. Fl.* (1864) 329; *Buch. N.Z. Grasses* (1879) t. 23. Calamagrostis Billardieri *Cockayne in Bot. Stewart Is.* (1909) 49.

Var. **tenuis** *Petrie MS.*—Smaller and much more slender. Leaves narrow, involute. Panicle smaller, with fewer branches. Spikelets rather smaller.

North and South Islands, Chatham Islands, Stewart Island: Abundant throughout in rocky or sandy places near the sea. Inland at Te Aroha, Upper Thames Valley. Var. *tenuis:* Catlin's River, Otago, *H. J. Matthews.*

Easily distinguished from *D. Forsteri* by the stouter habit and broader leaves, large spikelets, and by the more glabrous flowering glume, the lateral nerves of which are excurrent as short awns. It is a common Australian and Tasmanian plant.

4. **D. setifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 299, t. 65B.—Culms tufted, slender, wiry, smooth, 4–12 in. high. Leaves shorter than the culms, narrow, setaceous or filiform; sheaths smooth, striate, the uppermost long, tight; ligules oblong, membranous. Panicle erect, 1–2½ in. long, ⅛–⅓ in. broad, narrow, contracted; branches few, short, erect, scaberulous, sparingly divided. Spikelets few, pale-green, ⅛ in. long; pedicels short, scabrid. Two outer glumes subequal, oblong-lanceolate, acuminate, firm, spreading, keeled, 1–3-nerved, the lateral nerves usually short, keel scabrid; 3rd or flowering glume ⅛–¼ shorter, hard and almost coriaceous, silky at the base, the hairs almost as long as the glume, truncate and minutely 4-toothed at the tip; awn from the middle of the back, stout, scabrid, recurved, longer than the spikelet. Palea almost as long as the flowering glume, linear-oblong, 2-nerved. Rhachilla produced into a silky bristle ½ as long as the palea or more.—*Buch. N.Z. Grasses* (1880) 6; *Cheesem. Man. N.Z. Fl.* (1906) 870. Agrostis setifolia *Hook. f. Handb. N.Z. Fl.* (1864) 329; *Buch. N.Z. Grasses* (1879) t. 24B. Calamagrostis setifolia *Cockayne in Bot. Stewart Is.* (1909) 49.

North and South Islands, Stewart Island, Auckland Islands: Not uncommon in mountain districts from the East Cape and Mount Egmont southwards. 3000–5000 ft.

Allied to the preceding species, but a much smaller plant, panicle smaller and more slender, spikelets not much more than half the size, and flowering glume much more silky at the base and broadly truncate at the tip.

5. **D. avenoides** *Buch. N.Z. Grasses* (1880) 6.—Culms tufted, erect, slender, rigid, smooth, 9–24 in. high. Leaves much shorter than the culms, narrow, in slender forms almost filiform, smooth, strongly involute; sheaths smooth, deeply grooved, the uppermost long; ligules short, broad. Panicle erect, 2–5 in. long, ¼–½ in. broad, narrow, contracted, usually dense; branches short, erect, sparingly divided. Spikelets pale-green, ⅛–¼ in. long; pedicels shorter than the spikelets. Two outer glumes subequal, lanceolate, acuminate, sharply keeled, rigid, 1- or rarely 3-nerved, keel scabrid, sides smooth or minutely rough; 3rd or flowering glume slightly shorter, hard, convolute, scabrid, slightly silky at the base, minutely 2–4-cuspidate; awn from below the middle, stout, recurved, twisted below the bend, longer than the spikelet. Palea almost as long as the flowering glume, linear, hyaline, 2-nerved. Rhachilla produced into a silky bristle nearly ½ as long as the palea.—*Cheesem. Man. N.Z. Fl.* (1906) 871. Agrostis avenoides *Hook. f. Handb. N.Z. Fl.* (1864) 330; *Buch. N.Z. Grasses* (1879) t. 24A. Calamagrostis avenoides *Cockayne in Bot. Stewart Is.* (1909) 49.

Var. **brachyantha** *Hack. MS.* — Culms taller and more slender, 1–3 ft. high. Leaves narrower, filiform, often strict and wiry. Spikelets smaller, about ⅛ in. long; rhachilla shorter and more delicate.

Zotov. Trans 73 : 234. merges Dichelachne in Deyeuxia

North and South Islands, Stewart Island : Var. *brachyantha* common throughout, ranging from sea-level to 3500 ft., the typical state apparently confined to mountain districts in the South Island, through which it appears to be generally distributed. Nelson—Wairau Gorge, *T. F. C.* Canterbury—Craigieburn Mountains, *Petrie!* Rangitata Valley, *Sinclair* and *Haast;* Tasman Valley, *T. F. C.* Otago—Not uncommon in upland districts, *Hector* and *Buchanan! Petrie! Cockayne!*

The typical state is well characterized by its large spikelets, which no doubt induced Hooker to give it the name of *avenoides;* but the var. *brachyantha* is an exceedingly puzzling form. Professor Hackel has no hesitation in placing it under *D. avenoides*, but most New Zealand botanists, including myself, have been accustomed to regard it as a state of *D. quadriseta*, to which it seems to show a very near approach, principally differing in the rather larger spikelets, with the rhachilla always produced at the back of the palea. It appears to me to be very much a matter of taste whether it should be placed under *D. avenoides* or *D. quadriseta*.

6. **D. Youngii** *Buch. N.Z. Grasses* (1880) 6, t. 25.—A tall perennial species. Culms erect, terete, glabrous, 1–4 ft. high, 3-noded, the uppermost node near the middle of the culm. Leaves much shorter than the culms, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, flat, smooth and glabrous or scaberulous on the upper surface, rather flaccid; sheaths long, close, terete, minutely scaberulous; ligules oblong, obtuse. Panicle 3–6 in. long, narrow, sometimes dense and cylindric, but frequently open below; rhachis smooth; branches short, erect, binate or ternate, sparingly divided; pedicels shorter than the spikelets, smooth. Spikelets $\frac{1}{4}$ in. long, pale-green. Two outer glumes subequal, narrow-lanceolate, acute, rigidly membranous, 1-nerved, scabrid on the keel; 3rd or flowering glume about $\frac{1}{6}$ shorter, lanceolate, acute, denticulate at the tip, scabro-punctate on the back, callus with silky hairs $\frac{1}{3}$ as long as the glume; awn short, almost terminal. Palea nearly as long as the glume. Rhachilla produced into a hairy bristle behind the palea, about $\frac{1}{3}$ its length.—*Cheesem. Man. N.Z. Fl.* (1906) 871. Agrostis Youngii *Hook. f. Handb. N.Z. Fl.* (1864) 330; *Buch. N.Z. Grasses* (1879) t. 25.

Var. **Petriei** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 57.—Awn arising from the middle of the back of the flowering glume, not terminal. Other characters as in the type.—D. Petriei *Cheesem. Man. N.Z. Fl.* (1906) 872. Calamagrostis Petriei *Hack. in Trans. N.Z. Inst.* xxxv (1903) 380.

South Island : Canterbury—Dry hillsides at the sources of the Waitaki River, *Haast;* Hooker Valley, Mount Cook district, *Petrie!* Mount Peel, *H. H. Allan!* Var. *Petriei:* Slopes of Mount Herbert, *A. Wall!* Otago—Swampy Hill, near Dunedin, *Petrie! A. Wall!* Mount Pisa, *Petrie.* 1500–3500 ft.

(Lab: II.)

7. **D. quadriseta** *Benth. Fl. Austral.* vii (1878) 581.—Culms tufted, erect, stout or slender, smooth or rather rough, 1–3 ft. high. Leaves much shorter than the culms, variable in width, sometimes $\frac{1}{8}$ in. broad and quite flat, at other times very narrow and setaceous or filiform, often involute, glabrous or minutely scaberulous; sheaths smooth or rough, grooved; ligules oblong, membranous. Panicle $1\frac{1}{2}$–6 in. long, very narrow and spike-like, dense, cylindric, rarely broader and obscurely lobed, pale-green or brownish-green, shining; branches numerous, short, erect, branched from the base. Spikelets small, about $\frac{1}{8}$ in. long, shortly pedicelled. Two outer glumes subequal, lanceolate, acuminate, keeled, keel minutely scabrid, slightly hairy at the base, tip minutely but distinctly 4-awned; dorsal awn attached below the middle, sometimes almost basal, usually not much longer than the outer glumes. Palea almost as long as the flowering glume, narrow, 2-nerved. Rhachilla either not at all produced at the back of the palea or very obscurely so.—*Cheesem. Man. N.Z. Fl.* (1906) 872. Agrostis

2. Deyeuxia conspicua (Forst) Zotov
Arundo conspicua Forst f. 1786 p. 7c.
D. sciurea (KBA.) Hk. f.

quadriseta *R. Br. Prodr.* (1810) 171; *Hook. f. Fl. Nov. Zel.* i (1853) 296; *Handb. N.Z. Fl.* (1864) 330; *Buch. N.Z. Grasses* (1879) t. 26. Avena quadriseta *Labill. Pl. Nov. Holl.* i (1806) 25, t. 32.

North and South Islands, Stewart Island: Not uncommon throughout. Sea-level to 2500 ft.

Also abundant in Australia and Tasmania. The rhachilla is seldom produced at the back of the palea, so that the plant technically falls into *Agrostis*. But it is so closely allied to *D. avenoides*, which is an undoubted *Deyeuxia*, that I have decided to leave it in that genus.

19. **DICHELACHNE** Endl.

Tall slender grasses. Leaves narrow, flat or convolute. Spikelets 1-flowered, numerous, arranged in long and narrow usually dense panicles; rhachilla disarticulating above the 2 outer glumes, very slightly or not at all produced beyond the flower. Glumes 3; 2 outer subequal or slightly unequal, empty, persistent, narrow, sharply acuminate, keeled, membranous; 3rd or flowering glume almost as long, keeled, entire or shortly 2-fid, furnished with a long flexuous awn inserted on the back just below the tip, base of the glume with a hairy callus. Palea slightly shorter than the glume, narrow, 2-nerved. Stamens 2–3. Styles short, distinct; stigmas plumose. Grain narrow, enclosed in the slightly hardened flowering glume and palea.

The genus is confined to the two following species, both of which extend to Australia and Tasmania.

Panicle dense. Spikelets $\frac{1}{3}$ in. Awn 1 in., not twisted at the base .. 1. *D. crinita.*

Panicle lax. Spikelets $\frac{1}{4}$ in. Awn $\frac{1}{2}$–$\frac{3}{4}$ in., usually twisted at the base 2. *D. sciurea.*

1. **D. crinita** *Hook. f. Fl. Nov. Zel.* i (1853) 293. — Annual. Culms tufted, tall, slender, erect, 2–3 ft. high, leafy at the base. Leaves much shorter than the culms, flat or convolute, glabrous or the lower ones sometimes softly pubescent; margins smooth or slightly scaberulous; sheaths grooved, the upper rather long; ligules short, broad. Panicle very dense and spike-like, 3–6 in. long or more, bristling with the numerous awns which almost conceal the spikelets, pale-green, shining; branches numerous, short, erect. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. long. Two outer glumes more or less unequal, very narrow, long-acuminate, membranous or hyaline, keel green and scabrous; 3rd or flowering glume distinctly shorter, convolute, smooth or slightly rough, produced into a hyaline entire or 2-fid tip; awn very long, about 1 in., straight or flexuous, not twisted at the base. Palea about $\frac{1}{4}$ shorter than the flowering glume, linear, 2-nerved. — *Hook. f. Handb. N.Z. Fl.* (1864) 326; *Fl. Tasm.* ii (1860) 111; *Benth. Fl. Austral.* vii (1878) 574; *Buch. N.Z. Grasses* (1879) t. 16; *Cheesem. Man. N.Z. Fl.* (1906) 873. D. Hookeriana *and* D. Forsteriana *Trin. and Rupr. in Mèm. Acad. Petersb. Sèr.* vi, 5 (1842) 3, 4. Agrostis crinita *R. Br. Prodr.* (1810) 170; *A. Rich. Fl. Nouv. Zel.* (1832) 136; *A. Cunn. Precur.* (1836) n. 246; *Raoul Choix* (1846) 39. Anthoxanthum crinitum *Forst. f. Prodr.* (1786) n. 18.

Var. **intermedia** *Hack. MSS.*—Rather more slender; panicle narrower and laxer. A passage form into *D. sciurea.*

North and South Islands, Stewart Island, Chatham Islands: Plentiful in dry open situations throughout. Sea-level to 3000 ft. Also abundant in Australia and Tasmania.

+ D. micrantha (Cav.) Druce 1916 p. 619. But this change had been made by Domin (1915) see also N. Aust. & Skotb. Phanerogams of Easter Is. : 67.

(L.64)

2. **D. sciurea** *Hook. f. Fl. Nov. Zel.* i (1853) 294. — Smaller than *D. crinita* and more slender. Culms tufted, 1–2 ft. high, slender, quite glabrous. Leaves chiefly at the base of the culms and much shorter than them, narrow, flat or convolute, sometimes almost setaceous, glabrous or the lower ones pubescent; sheaths smooth; ligules short, broad. Panicle 3–6 in. long, much more lax and open than in *D. crinita;* branches slender, capillary, scabrid. Spikelets $\frac{1}{4}$ in. long, rarely more. Two outer glumes equal or nearly so, long-acuminate, margins hyaline, keel smooth or scabrid; 3rd or flowering glume nearly as long, convolute, smooth or slightly scabrous, entire or 2-fid at the tip; awn $\frac{1}{2}$–$\frac{3}{4}$ in. long, flexuous, usually but not invariably twisted at the base, inserted on the back of the glume close to the tip. Palea narrow-linear, 2-fid.—*Hook. f. Handb. N.Z. Fl.* (1864) 326; *Fl. Tasm.* ii (1860) 111, t. 158A; *Benth. Fl. Austral.* vii (1878) 574; *Buch. N.Z. Grasses* (1879) t. 16 (*in part*); *Cheesem. Man. N.Z. Fl.* (1906) 874. D. Sieberiana *Trin. and Rupr. in Mèm. Acad. Petersb. Sèr.* vi, 5 (1842) 2. D. montana *Endl. Prodr. Fl. Ins. Norf.* (1833) 24. Agrostis sciurea *R. Br. Prodr.* (1810) 171. Stipa micrantha *Cav. Ic.* v (1791–1801) 42; *F. Muell. in Journ. Bot.* (1878) 327 (*not of Benth. Fl. Austral.* vii (1878) 566).

Avenella sciurea Forst. f. 1926–9.

Var. **inaequiglumis** *Hack. MSS.*—Panicle with longer flaccid branches; spikelets more laxly arranged. Two outer glumes unequal, acute but not cuspidate, keel sharply scabrid; awn of flowering glume almost apical, not twisted at the base.

North Island: From the North Cape to Wellington; not so plentiful as *D. crinita.* South Island: Vicinity of Westport, *W. Townson!* Has also been recorded from Marlborough (*Buchanan*), Canterbury (*Armstrong*), and Greymouth (*T. Kirk*), but I have seen no specimens. see Trans 57: 69

Also in Australia, Tasmania, and Norfolk Island.

51?

20. **DESCHAMPSIA** Beauv. 1812.

Perennial grasses. Leaves narrow, flat or convolute. Spikelets rather small, 2-flowered, arranged in lax or contracted panicles; rhachilla disarticulating above the 2 outer glumes, produced between the flowering glumes and above the upper flower as a naked or hairy bristle, rarely ending in an imperfect flower. Glumes 4; 2 outer slightly unequal, persistent, empty, keeled, acute, membranous, shining; 3rd and 4th (or flowering glumes) membranous or almost hyaline, toothed at the apex; dorsal awn slender, twisted at the base, sometimes very small or wanting. Palea narrow, 2-nerved. Lodicules 2, ovate. Stamens 3. Styles distinct; stigmas plumose. Grain oblong, enclosed within the unaltered flowering glume and palea.

Species about 25, dispersed through most cold or temperate regions. One of the New Zealand species extends through the whole range of the genus; the remaining 6 are endemic. These constitute a somewhat anomalous group, differing from the true *Deschampsiae* in the awn being almost terminal and very small, or altogether absent. They may ultimately form a separate genus.

* Awn from the middle of the back of the flowering glume or below it.

Tall, 1–4 ft. high. Panicle long, 4–12 in. Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. .. 1. *D. caespitosa.*

** Awn from immediately below the tip of the flowering glume or wanting.

† *Rhachilla glabrous.*

Forming dense patches $\frac{1}{2}$–$1\frac{1}{2}$ in. high. Leaves short, curved. Panicle $\frac{1}{4}$–$\frac{3}{4}$ in., dense. Spikelets straw-yellow, shining. Awn wanting or rarely present .. .. .. 2. *D. pusilla.*

Slender, 3–9 in. Leaves shorter than the culms, involute. Panicle slender, lax, 1–3 in. long. Spikelets pale-green, apex of flowering glume irregularly denticulate. Awn wanting .. 3. *D. novae-zealandiae.*

D. Kingii (Hook.f.) Desv. in Gay. Flora Chilena. 5 VI (1853) 335.

Slender, 6–18 in. Leaves flaccid, flat or involute, often capillary. Panicle very slender, 3–6 in. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in., pale-green; apex of flowering glume 3-toothed. Awn usually present .. .. 4. *D. Chapmani.*

†† *Rhachilla hairy.*

Very slender, flaccid, 6–14 in. Leaves capillary. Panicle very slender, lax, 2–6 in. Spikelets small, $\frac{1}{10}$ in.; apex of flowering glume 3-toothed. Awn usually present .. .. 5. *D. tenella.*

Slender, tufted, 2–8 in. Leaves short, strict. Panicle lax, deltoid, $\frac{3}{4}$–2 in. Spikelets few, $\frac{1}{8}$–$\frac{1}{6}$ in.; apex of flowering glume 3-toothed. Awn usually present. Hairs of rhachilla long, copious .. .. 6. *D. gracillima.*

Slender, 3–6 in. Leaves short, flat. Panicle sparingly branched, lax, 1–2 in.; spikelets few. Flowering glume irregularly denticulate; awn wanting. Rhachilla with a minute empty glume at the apex .. .. .. 7. *D. penicillata.*

1. **D. caespitosa** *Beauv. Agrost.* 91 (1812) t. 18, f. 3.—Culms densely tufted, forming large tussocks, smooth, shining, rather stout or slender, leafy, 1–4 ft. high. Leaves rather stiff, narrow, flat or convolute, rough on the upper surface and margins; sheaths shining, smooth or rough; ligules long, membranous, acute. Panicles 4–12 in. long, usually rather narrow and dense in New Zealand examples, inclined or nodding above; branches in somewhat distant fascicles, capillary, smooth or minutely scaberulous. Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. long, shining, pale yellow-green or purplish. 5-6 mm. Two outer glumes keeled, acute or subacute, 1-nerved or the upper 3-nerved; 3rd and 4th or flowering glumes equalling the empty glumes or rarely exceeding them, truncate, 4-toothed, silky at the base, the 4th separated from the 3rd by a distinct hairy internode, sometimes absent so that the spikelet becomes 1-flowered; awn from the middle of the back or below it, not twisted at the base or obscurely so, usually not far exceeding its glume. Rhachilla produced into a distinct hairy pedicel above the 4th glume.—*Hook. f. Fl. Nov. Zel.* i (1853) 301; *Fl. Tasm.* ii (1860) 118; *Handb. N.Z. Fl.* (1864) 334; *Benth. Fl. Austral.* vii (1878) 587; *Buch. N.Z. Grasses* (1879) t. 37; *Cheesem. Man. N.Z. Fl.* (1906) 875. Aira caespitosa *Linn. Sp. Plant.* (1753) 64. A. Kingii *Hook. f. Fl. Antarct.* ii (1847) 376, t. 135. A. australis *Raoul Choix* (1846) 12. Agrostis aucklandica *Hook. f. Fl. Antarct.* i (1844) 96.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Wet places from the Lower Waikato southwards, plentiful. Sea-level to 3500 ft. Lake Rotoma Kirk Trans 5: 328

An abundant grass in all cool and temperate regions. The New Zealand form has the spikelets rather larger and the awn of the flowering glume inserted somewhat higher up than is usual in northern specimens, and is distinguished as var. *macrantha* by Hackel.

2. **D. pusilla** *Petrie in Trans. N.Z. Inst.* xxiii (1891) 403.—Culms densely tufted, branched at the base, 1–2 in. high, forming small compact patches. Leaves numerous, shorter than the culms, setaceous, curved, convolute; sheaths broad, membranous, grooved; ligules large for the size of the plant, acute, much broader than the blade, decurrent along the margins of the sheath. Panicle small, contracted, sometimes almost spiciform, straw-yellow, shining, $\frac{1}{4}$–$\frac{3}{4}$ in. long; branches few, short, small, the lowermost bearing 2–3 spikelets, the upper 1 only. Spikelets $\frac{1}{8}$ in. long, 2-flowered, rarely 3-flowered. Two outer glumes almost equal in length, hyaline, the lower narrower, 1-nerved, the 2nd 3-nerved; 3rd and 4th

or flowering glumes faintly silky or almost glabrous at the base, broadly oblong, hyaline, indistinctly 5-nerved, truncate, irregularly 3-toothed or erose, awnless or with a minute dorsal awn inserted just below the tip. Palea as long as the glume, deeply bifid, 2-nerved. Rhachilla elongated between the flowering glumes and produced beyond the upper flower into a short bristle, quite glabrous.—*Cheesem. Man. N.Z. Fl.* (1906) 876.

South Island: Otago — Hector Mountains, *Petrie!* Humboldt Mountains, *Cockayne!* 5000–6500 ft.

A very remarkable little plant, quite distinct from any of the following species.

3. **D. novae-zealandiae** *Petrie in Trans. N.Z. Inst.* xxiii (1891) 402.—Culms densely tufted, branched at the base, slender, smooth, leafy below, 3–9 in. high, rarely more. Leaves from $\frac{1}{3}$ to $\frac{1}{2}$ the length of the culms, very narrow, setaceous, involute; sheaths broad, pale, membranous, grooved; ligules long, scarious, acute, broader than the blade at the base. Panicle slender, erect, 1–3 in. long, usually lax but sometimes contracted; branches few, capillary, smooth or minutely scaberulous, sparingly divided. Spikelets few, small, $\frac{1}{10}$–$\frac{1}{8}$ in. long, pale-green, shining, 2-flowered. Two outer glumes unequal, the lower about $\frac{1}{2}$ the length of the spikelet, oblong-lanceolate, acute, 1-nerved, the upper about $\frac{2}{3}$ the length of the spikelet, broader and more obtuse, 3-nerved; 3rd and 4th or flowering glumes broadly oblong, hyaline, membranous, faintly 3–5-nerved, quite glabrous at the base, broadly truncate at the apex and irregularly minutely denticulate, awn wanting. Palea bifid, 2-nerved, nerves faintly ciliate. Rhachilla elongated between the flowering glumes and produced beyond the upper flower into a slender bristle, quite glabrous.—*Cheesem. Man. N.Z. Fl.* (1906) 876. D. Hookeri *T. Kirk in Journ. Bot.* xxiv (1891) 237 (*in part*).

South Island: Canterbury—Lake Lyndon, *Petrie!* Castle Hill, *T. Kirk!* Poulter River, *Cockayne.* Westland—Kelly's Hill, *Petrie! Cockayne!* Otago—Naseby, Pembroke, Mount St. Bathan's, Hector Mountains, Lake Te Anau, *Petrie!* 1000–5000 ft.

Although very closely allied to *D. Chapmani* and *D. tenella* this appears to be sufficiently distinct from both in the irregularly denticulate apex of the flowering glume and the total absence of the dorsal awn. Mr. Kirk united all three under the name of *D. Hookeri!*

4. **D. Chapmani** *Petrie in Trans. N.Z. Inst.* xxiii (1891) 401.—Culms tufted, branched at the base, quite smooth, leafy, 6–18 in. high. Leaves longer or shorter than the culms, very narrow, flat or involute, often almost filiform, flaccid; sheaths long, narrow, deeply grooved; ligules elongated, acute, broader than the blade at the base. Panicle very slender, 3–6 in. long or more, effuse or contracted, laxly and sparingly branched; branches capillary, minutely scaberulous, usually trichotomously divided. Spikelets few, small, about $\frac{1}{8}$ in. long, pale-green, glistening, 2-flowered. Two outer glumes unequal, much shorter than the spikelet, oblong-lanceolate, membranous, the lower short, 1-nerved, the upper $\frac{1}{2}$ longer, equalling the lower flower or slightly exceeding it, 3-nerved; 3rd and 4th or flowering glumes broadly oblong, membranous, faintly 3–5-nerved, glabrous at the base or rarely with few very short hairs, truncate at the apex and more or less irregularly 3–5-toothed; awn usually present on both glumes, from the back a little distance below the tip. Palea bifid, 2-nerved, nerves ciliate. Rhachilla elongated between the flowering glumes and produced beyond the upper flower into a slender bristle, quite glabrous.—*Cheesem. Man. N.Z. Fl.* (1906) 877. D. Hookeri *T. Kirk in Journ. Bot.* xxiv (1891) 237 (*in part*). Catabrosa antarctica *Hook. f. Fl. Antarct.* i (1844) 102, t. 56. Triodia antarctica *Benth. in Journ. Linn. Soc.* xix (1881) 111.

South Island: Canterbury—Arthur's Pass, *T. Kirk!* Otago—Clinton Saddle, *Petrie!* Milford Sound, *T. Kirk!* Stewart Island: Mount Anglem, *Cockayne.* Auckland and Campbell Islands, Antipodes Island, Macquarie Island: *Hooker, T. Kirk! F. R. Chapman! H. Hamilton!* Sea-level to 3500 ft.

Very close to the following species, of which it may prove to be a variety, and from which it is mainly separated by the glabrous rhachilla and rather larger spikelets.

5. **D. tenella** *Petrie in Trans. N.Z. Inst.* xxiii (1891) 402.—Culms tufted, branched at the base, extremely slender, flaccid, quite smooth, leafy throughout, 6–14 in. high. Leaves bright-green, very narrow, capillary, involute, flaccid, the uppermost often exceeding the young panicle; sheaths smooth, grooved; ligules long, acute, membranous, broader than the blade and decurrent along the margins of the sheaths. Panicle very slender, 2–6 in. long, contracted at first, but becoming lax and somewhat effuse; branches in pairs, few, rather distant, capillary, scabrid, trichotomously divided. Spikelets few towards the tips of the branches, small, $\frac{1}{10}$ in. long, pale, glistening, 2-flowered. Two outer glumes unequal, much shorter than the spikelet, membranous, 1-nerved or the upper 3-nerved; 3rd and 4th or flowering glumes broadly oblong, delicately hyaline, faintly 5-nerved, silky at the base, truncate at the apex and 3-toothed, the middle tooth often bifid, the 4th always with a minute dorsal awn inserted just below the apex, the 3rd frequently awnless. Palea bifid, 2-nerved, the nerve finely ciliate. Rhachilla elongated between the flowering glumes and more or less silky, produced above the upper flower into a silky bristle.—*Cheesem. Man. N.Z. Fl.* (1906) 878; *Ill. N.Z. Fl.* ii (1914) t. 224. D. Hookeri *T. Kirk in Journ. Bot.* xxiv (1891) 237 (*in part*). Catabrosa antarctica *Hook. f. Fl. Nov. Zel.* i (1853) 308 (*but not of Fl. Antarct.* i, 102); *Buch. N.Z. Grasses* (1879) t. 41B.

North Island: Ruahine Mountains, *Colenso!* Tararua Mountains, *H. H. Travers! Petrie!* South Island: Nelson—Mount Arthur, *A. McKay!* Otago—Near Dunedin, Catlin's River, Clinton Saddle, *Petrie!* Sea-level to 4500 ft.

This differs from both *D. novae-zealandiae* and *D. Chapmani* in the silky rhachilla, and from the former in addition in the dorsal awn being present in at least the upper flower. It varies greatly in the size of the spikelets and in the proportionate length of the outer glumes. Mr. Petrie's original specimens from Catlin's River have the spikelets barely more than $\frac{1}{12}$ in. long, and the upper outer glume is not half the length of the spikelet; but those from the Clinton Valley, and Mr. Colenso's from the Ruahine Range, have much larger spikelets with longer outer glumes.

6. **D. gracillima** *T. Kirk in Journ. Bot.* xxiv (1891) 237.—Culms tufted, usually with intravaginal branches near the base, erect, slender, glabrous, 2–8 in. high. Leaves towards the base of the culms and much shorter than them, strict, erect, very narrow, setaceous or filiform, convolute; sheaths rather lax, grooved; ligules long, membranous, usually split at the tip. Panicle erect, ovate or deltoid, open, $\frac{3}{4}$–2 in. long; branches few, binate, capillary, smooth or almost so. Spikelets $\frac{1}{8}$–$\frac{1}{6}$ in. long, on pedicels longer than themselves, 2-flowered. Two outer glumes unequal, 3-nerved, shorter than the spikelet; 3rd and 4th or flowering glumes densely silky at the base, oblong, membranous, 5-nerved, truncate at the tip and 3-toothed, the middle tooth entire or bifid or irregularly erose, the 3rd awnless or very obscurely awned, the 4th usually with a minute dorsal awn inserted just below the tip. Palea linear-oblong, bifid, 2-nerved, nerves finely ciliate. Rhachilla elongated between the flowering glumes and densely silky, produced above the upper flower into a long silky bristle.—*Cheesem. Man. N.Z. Fl.* (1906) 878.

Auckland Islands: Carnley Harbour, altitude 1000 ft., *T. Kirk! B. C. Aston!*

The densely tufted habit, short strict erect leaves, deltoid few-flowered panicle, large spikelets, and densely hairy rhachilla distinguish this from all its allies.

7. **D. penicillata** *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 354.—Culms tufted, slender, glabrous, leafy, 3–6 in. high. Leaves shorter than the culms, radical and cauline; blades short, $\frac{3}{4}$–$1\frac{1}{2}$ in. long, narrow, flat or involute, striate; sheaths pale, membranous, deeply grooved, the uppermost long, enclosing the culm up to the base of the panicle; ligules long, pointed, scarious, broader than the blade at the base. Panicle small, 1–2 in. long, few-flowered; branches few, capillary, the lower ones bearing 2–3 spikelets, the upper 1-spiculate. Spikelets $\frac{1}{8}$–$\frac{1}{6}$ in. long, pale yellow-green, shining, 2-flowered. Two outer glumes almost equalling the flowering glumes, subequal, oblong-lanceolate, subacute, hyaline, 3-nerved; 3rd and 4th or flowering glumes oblong, very delicate, with white hyaline tips, 5-nerved, silky at the base, obtuse or almost truncate at the tip and irregularly minutely denticulate, awn wanting. Palea linear-oblong, 2-nerved, nerves silky. Rhachilla elongated between the flowering glumes and produced beyond the upper flower into a bristle bearing a minute empty glume at its summit, silky throughout.—*Cheesem. Man. N.Z. Fl.* (1906) 879; *Vascl. Fl. Macquarie Is.* (1919) 34.

Macquarie Island: In swamps, *A. Hamilton!*

I regret that I have only seen two small and immature specimens of this curious little plant, which is by no means closely related to any other New Zealand species.

21. **TRISETUM** Pers. 1805

Perennial or rarely annual grasses. Leaves flat. Spikelets rather small, usually 2-flowered, more rarely 3–6-flowered, arranged in a narrow dense or lax panicle; rhachilla disarticulating above the 2 outer glumes, more or less produced between the flowering glumes and beyond the upper flower into a short bristle. Two outer glumes persistent, empty, equal or unequal, acute, keeled, 1–3-nerved. Flowering glumes 2–3, rarely more, equalling or exceeding the empty glumes, membranous with broad hyaline margins, 2-toothed at the apex, the teeth often produced into bristles or short awns; dorsal awn from the back below the tip, slender, straight or bent, often twisted at the base. Palea strongly 2-nerved, 2-toothed. Stamens 3. Styles very short, distinct; stigmas plumose. Grain enclosed within the flowering glume and palea, free.

A genus of about 60 species, most plentiful in the North Temperate Zone, but also found on the high mountains of the tropics and in South America and Australasia. One of the New Zealand species is widely spread, the rest are endemic.

* Awn at least as long as the glume, inserted on the back a little distance below the tip.

Glabrous or sparsely pubescent, 6–24 in. Panicle 2–10 in., rather lax. Empty glumes lanceolate, unequal .. .. .. 1. *T. antarcticum.*
Pilose, 2–3 ft. Panicle 2–10 in., very slender. Empty glumes oblong or oblong-obovate, subequal .. .. .. 2. *T. Youngii.*
Puberulous or tomentose, 2–12 in. Panicle dense, cylindric, $\frac{1}{2}$–2 in. 3. *T. subspicatum.*

** Awn very short, from between the terminal teeth of the glume.

Puberulous, 6–12 in. Panicle dense, cylindric, 1–3 in. Teeth of flowering glumes short .. .. 4. *T. Cheesemanii.*

1. **T. antarcticum** (Forst.) *Trin. in Mém. Acad. Petersb. Sér.* vi, 1 (1831) 61.—Perennial, very variable in size and degree of robustness. Culms tufted, slender, smooth or sparsely pubescent, 6–24 in. high. Leaves usually shorter than the culms, narrow, $\frac{1}{15}$–$\frac{1}{6}$ in. broad, flat or involute, flaccid, smooth or the margins finely scaberulous; sheaths long, narrow, grooved;

ligules short, truncate, hyaline, ciliolate. Panicle very variable, erect or inclined, contracted or rather lax, usually narrow, rarely broad and effuse, 1–10 in. long; branches short, slender, suberect, simple or again divided. Spikelets compressed, pale-green or brownish-green, shining, 2–3-flowered, rarely 1-flowered or 4-flowered, $\frac{1}{5}$–$\frac{1}{4}$ in. long. Two outer glumes unequal, the lower from less than $\frac{1}{2}$ to $\frac{2}{3}$ the length of the upper, lanceolate, acute, scabrid on the keel; margins broad, hyaline. Flowering glumes exceeding the empty glumes, oblong-lanceolate, 2-cuspidate at the apex, scabrous-pubescent on the back, margins hyaline; awn from the back a little distance from the tip, sometimes $\frac{1}{4}$-way down, not twisted, recurved, twice as long as the glume. Palea almost as long as the flowering glume. Rhachilla clothed with copious long silky hairs between the flowering glumes, produced beyond the upper flower into a silky bristle.—*Hook. f. Fl. Nov. Zel.* i (1853) 301, t. 68B; *Handb. N.Z. Fl.* (1864) 335; *Buch. N.Z. Grasses* (1879) t. 39; *Cheesem. Man. N.Z. Fl.* (1906) 880. Aira antarctica *Forst. f. Prodr.* (1786) n. 41. Avena antarctica *Roem. and Schult. Syst.* ii (1817) 676; *A Rich. Fl. Nouv. Zel.* (1832) 139; *A. Cunn. Precur.* (1836) n. 257; *Raoul Choix* (1846) 39. Danthonia pallida *A. Cunn. Precur.* (1836) n. 256 (*not of R. Br.*).

Var. **lasiorhachis** *Hack. MSS.*—Culms, leaf-sheaths, rhachis, and branches of the panicle densely pubescent. Other characters as in the type.

Var. **tenelium** *Petrie in Trans. N.Z. Inst.* xliv (1912) 187.—Smaller and much more slender. Culms erect, greatly exceeding the involute setaceous leaves. Panicle short, dense, oblong; or longer, linear, and more open. Spikelets mostly 2-flowered.

North and South Islands, Stewart Island, Chatham Islands: Abundant throughout. Sea-level to 4500 ft. The larger forms, common in the lowlands and in moist mountain-valleys, are good pasture-grasses. Var. *tenellum.*—South Island: Nelson—Lake Rotoiti, *T. Kirk!* Canterbury—Shingly river-valleys in the Mount Cook district, *Petrie! T. F. C.;* Takitimo Mountains, Mount Ida, Mount Buster, *Petrie!* 1800–3500 ft.

2. **T. Youngii** *Hook. f. Handb. N.Z. Fl.* (1864) 335. — Culms tufted, slender, erect, pilose or glabrous, 1–3 ft. high. Leaves mostly at the base of the culms and much shorter than them, $\frac{1}{12}$–$\frac{1}{4}$ in. broad, flat, smooth, pilose with long soft hairs; sheaths grooved, glabrous or pilose; ligules short, truncate, lacerate, hyaline. Panicle slender, very narrow, 2–8 in. long; rhachis pilose; branches short, close, suberect, few-flowered, also pilose. Spikelets compressed, pale-green or yellow-brown, shining, 1–3-flowered, about $\frac{1}{5}$ in. long. Two outer glumes almost as long as the flowering glumes, subequal or the lower about $\frac{1}{4}$ shorter than the upper, oblong or oblong-obovate, suddenly acuminate, membranous, scabrid along the keel. Flowering glumes oblong-lanceolate, shortly 2-cuspidate, minutely rough on the back; awn from $\frac{1}{5}$ to $\frac{1}{4}$ way down the back, rather stout, recurved, nearly as long again as the glume. Palea almost equalling the flowering glume. Rhachilla nearly glabrous, produced between the flowering glumes and above the upper flower.—*Buch. N.Z. Grasses*, t. 40B; *Cheesem. Man. N.Z. Fl.* (1906) 881; *Ill. N.Z. Fl.* ii (1914) t. 225.

North Island: Mount Hikurangi, East Cape, *Adams* and *Petrie!* ravines at the western base of Ruapehu and Ngauruhoe, *T. F. C.;* Tararua Range, *Buchanan! B. C. Aston!* South Island: Not uncommon in subalpine localities, especially on the western side. 3000–5000 ft.

Best distinguished from *T. antarcticum* by the much broader oblong or oblong-obovate empty glumes; but it is usually a taller and more pilose plant, with a narrower panicle.

T. saxiticolum, Cheesem. & Trans 57:1926:60

spicatum (L.) Richter. 1890 p. 59.

3. **T. subspicatum** *Beauv. Agrost.* (1812) 88.—Culms densely tufted, stout or slender, pubescent or tomentose, in New Zealand specimens from 2 to 12 in. high, rarely more. Leaves numerous at the base of the culms and much shorter than them, firm, erect, rather strict, flat, more or less downy or almost glabrous, $\frac{1}{12}$–$\frac{1}{6}$ in. broad; sheaths rather lax, deeply grooved; ligules short, scarious, lacerate. Panicle short and dense, cylindric or almost ovoid, rarely slightly lobed or interrupted at the base, $\frac{1}{2}$–2 in. long; rhachis densely tomentose; branches short, erect. Spikelets compressed, whitish or yellowish-green, rarely purplish, shining, 2–3-flowered, $\frac{1}{6}$–$\frac{1}{4}$ in. long. Two outer glumes unequal, lanceolate, keeled, scabrid along the keel, the outer 1-nerved, the 2nd 3-nerved. Flowering glumes oblong-lanceolate, 2-cuspidate or shortly 2-awned at the tip, hairy at the base, keel scabrid above, sides minutely rough; awn from $\frac{1}{6}$ to $\frac{1}{4}$ way down the back, longer than the glume, straight or recurved. Palea about $\frac{1}{5}$ shorter than the flowering glume, 2-nerved, scabrid along the nerves.—*Hook. f. Fl. Antarct.* i (1853) 97; *Handb. N.Z. Fl.* (1864) 335; *Benth. Fl. Austral.* vii (1878) 588; *Buch. N.Z. Grasses* (1879) t. 40A; *Cheesem. Man. N.Z. Fl.* (1906) 881.

Aira spicata L. 1753. See Britton & Brown 1:217

South Island: Not uncommon in alpine and subalpine localities throughout. Auckland Islands: *T. Kirk! J. S. Tennant!* Campbell Island: *Sir J. D. Hooker! R. M. Laing, H. C. Field!* Usually from 3500 to 5500 ft., but descends almost to sea-level in the Auckland Islands.

A common alpine grass in most countries, extending into both Arctic and Antarctic regions.

Koeleria Petrie 48—192.

4. **T. Cheesemanii** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 381.—Culms rather stout, erect, 3–12 in. high, naked and puberulous above, leafy below, 2-noded, the upper node in the lower $\frac{1}{4}$ of the culm. Leaves crowded at the base of the culms, flat, $\frac{1}{10}$–$\frac{1}{8}$ in. broad, firm, erect, glaucous, finely scaberulous on the veins and margins; sheaths rather lax, subcompressed, minutely puberulous; ligules short, truncate, denticulate. Panicle very dense, cylindrical, 1–2$\frac{1}{2}$ in. long, $\frac{1}{2}$ in. broad; rhachis tomentose; branches densely imbricate, short, binate or ternate. Spikelets elliptic-lanceolate, compressed, whitish-yellow, shining, 2-flowered, about $\frac{1}{4}$ in. long. Two outer glumes slightly unequal, lanceolate, acute, scabrid on the keel, minutely rough on the sides, the lower 1-nerved, the 2nd 3-nerved. Flowering glumes lanceolate, very shortly 2-cuspidate, slightly hairy at the base, minutely rough, faintly 5-nerved; awn very short indeed, from between the terminal teeth or just below them. Palea $\frac{1}{4}$ shorter than the glume, scabrid along the nerves. Rhachilla produced between the flowering glumes and beyond the upper flower, silky.

North Island: Mount Hikurangi, *Petrie!* South Island: Marlborough—Mount Blairich, *J. H. Macmahon!* Canterbury—Craigieburn Mountains, *Petrie! Cockayne!* Hooker Glacier, *T. F. C.* Otago—*Petrie!* 3000–5000 ft.

This has much of the habit and appearance of *T. subspicatum*, but differs from it, and from all the other species, in the very shortly bidentate flowering glume, with the intermediate awn springing almost from between the teeth, not from the back some distance below the teeth, as is usual in the genus. In consequence of this peculiarity Mr. Petrie has proposed to remove the species to the genus *Koeleria* (see Trans. N.Z. Inst. xlviii (1916) 192). It is possible that he may be right in his contention, but as Professor Hackel, who first described the species, and was also the first to recognize its near approach to *Koeleria*, nevertheless decided, after full examination, to retain it in *Trisetum*, I have thought it best to follow the same course. Technically speaking, *Trisetum* and *Koeleria* fall into two separate families, but nevertheless most botanists find a difficulty in apportioning the species. Domin, in monographing *Koeleria*, found

see "The grass genus Amphibromus" J.R. Swallen Ann. J. Bot. xviii: 1931: 411-415. 5 spp. mcoy. 2 aust. 1 N.Z. 2 S. America.

it necessary to expunge 13 species of *Trisetum* that had been, according to his views, erroneously placed in *Koeleria*. The excellent botanist Boissier, in his classic "Flora Orientalis," described the same species in one part of his work as a *Koeleria*, and in another as a *Trisetum!* Personally, I regard the position of *Trisetum Cheesemanii* as very much a matter of taste. Its resemblance to *Koeleria* is admitted; but its equally great resemblance to *Trisetum subspicatum* must also be taken into account.

22. **AMPHIBROMUS** Nees. 1843.

Slender glabrous grasses. Leaves flat. Spikelets 5–10-flowered, arranged in a lax panicle; rhachilla slender, hairy, jointed between the flowers. Two outer glumes persistent, empty, acute, keeled, 5-nerved at the base, with scarious margins, awnless. Flowering glumes more rigid, rounded on the back, prominently 5-nerved, often split at the tip with the lobes produced into short awns; dorsal awn from about the middle of the back, straight or bent, often twisted. Palea thin, 2-toothed. Stamens 3. Styles short, distinct; stigmas plumose. Lodicules 2. Grain oblong, glabrous, enclosed within the flowering glume and palea.

A small genus of 2 species, the present one and another endemic in Australia.

1. **A. fluitans** *T. Kirk in Trans. N.Z. Inst.* xvi (1884) 374, t. 28.—Culms weak, branched, creeping and rooting at the base, erect or floating above, glabrous, 12–18 in. long. Leaves numerous, sheathing the culm up to the base of the panicle, narrow, flat, minutely scabrid on the margins and veins; sheaths rather broad and lax, compressed, grooved, longer than the internodes; ligules long, pointed, hyaline. Panicle 2–4 in. long, narrow, lax, few-flowered; branches few, short, capillary, scaberulous, the lowermost with 2–3 spikelets, the upper 1-spiculate. Spikelets compressed, pale-green, usually about $\frac{1}{2}$ in. long without the awns, 4–7-flowered. Two outer glumes unequal, small, the upper not one-half the length of the flowering glume above it. Flowering glumes silky at the base, firm and rather rigid when in fruit, 5–7-nerved, scabrous on the back and sides; awn from the middle of the back, long, straight, scabrid, not bent nor twisted. Palea hyaline, 2-nerved, strongly ciliate on the nerves.—*Cheesem. Man. N.Z. Fl.* (1906) 882.

North Island: Auckland—Marshes near Waiuku, *H. Carse!* Lakes Whangape and Waikare, *T. F. C.*; Lake Waihi, *T. Kirk!* Taranaki—Swamps near New Plymouth, *T. F. C.* S. Island Lake Tekapo H.H.A. - see Allan Trans. 65 p. 281

Distinguished from the Australian *A. Neesii* by the weak decumbent habit, smaller panicle, narrower spikelets, shorter outer glumes, and straight awn.

23. **DANTHONIA** D.C. Lamol- 1805

Perennial or rarely annual grasses. Leaves very variable. Spikelets 3- to many-flowered, laterally compressed, arranged in a lax or dense panicle, rarely in a simple raceme; rhachilla disarticulating above the 2 outer glumes and between the flowering glumes, produced beyond the uppermost flower. Two outer glumes persistent, empty, equal or more or less unequal, keeled, acute or acuminate, 3–7-nerved, as long as the whole spikelet or slightly shorter. Flowering glumes 2 or more, rounded on the back, usually ciliate on the margins, 5–9-nerved, hairy, the hairs often collected into variously arranged tufts, 2-lobed at the tip, the lobes often produced into short awn-like bristles; awn from the sinus between the lobes, usually long and rigid and twisted, rarely reduced to

a mucro; callus at the base of the glume, hairy. Palea broad, hyaline, 2-keeled. Lodicules 2. Stamens 3. Styles distinct; stigmas plumose. Grain oblong, ellipsoid, or obovoid, free within the flowering glume and palea.

Species not far from 100, widely dispersed in both hemispheres, but chiefly in the South Temperate Zone, particularly abundant in Australia, New Zealand, and South Africa. Of the 13 species found in New Zealand, 2 extend to Australia, the rest are endemic.

* Two outer glumes shorter than the spikelet, very rarely almost equalling it.

† *Culms tall, stout. Panicle large; spikelets numerous.*

Culms 2–5 ft. Leaves $\frac{1}{4}$–$\frac{1}{3}$ in., often pilose. Panicle 6–18 in., lax. Awn straight, not flattened nor twisted at the base .. .. 1. *D. Cunninghamii.*
Culms $1\frac{1}{2}$–2 ft. Leaves terete, undulate, clothed with appressed hairs. Awn flattened at the base and twisted .. .. 2. *D. ovata.*

Culms 3–12 in. Panicle $\frac{3}{4}$–$1\frac{1}{4}$ in. Spikelets 2–3-flowered. Flowering glume very shortly bifid at the top. Awn short, straight. A tuft of hairs at the base of the glume, 2 minute tufts on each side, with a few hairs on the back .. .. .. 13. *D. nuda.*

1. **D. Cunninghamii** *Hook. f. Handb. N.Z. Fl.* (1864) 332.—Densely tufted, often forming large tussocks. Culms stout, 2–5 ft. high, $\frac{1}{4}$–$\frac{1}{2}$ in. diam. at the base, glabrous or more or less pilose. Leaves $1\frac{1}{2}$–4 ft. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, rigid and coriaceous, flat or concave, strongly nerved, midrib prominent beneath, glabrous or pilose on the margins and upper surface in the lower half of the leaf, margins scaberulous; sheaths rather lax, often $\frac{1}{2}$ in. broad or even more, deeply grooved, usually silky-pilose in the grooves; ligules reduced to a transverse line of densely set short silky hairs. Panicle large, erect or inclined, effuse or compact, 6–18 in. long; branches few or many, solitary or binate or in alternate fascicles, 3–12 in. long; branchlets slender, capillary, scaberulous, few-flowered. Spikelets rather distant, pedicelled, $\frac{1}{3}$–$\frac{1}{2}$ in. long without the awns, 3–7-flowered. Two outer glumes unequal, lanceolate, acute or acuminate,

D. flavescens var. hookeri Zotov.
D. antarctica Hooker non (Thunb.) Spreng. 1825
Petrie Subcant. Is. 2: 475.
What is D. glaucida Kirk Trans. 17: 224? Nom. Nud?

membranous, 3-nerved, the upper one shorter than the flowering glume above it. Flowering glumes clothed with long silky hairs at the base and along the lower half of the margins, glabrous elsewhere, 7–9-nerved, deeply 2-fid at the tip with the points produced into short awns; awn from between the lobes, about $\frac{1}{3}$ in. long, straight or recurved, not flattened nor twisted at the base. Palea nearly as long as the glume, linear-oblong.—*Buch. N.Z. Grasses* (1879) t. 29; *Cheesem. Man. N.Z. Fl.* (1906) 884. D. antarctica *var.* laxiflora *Hook. f. Fl. Nov. Zel.* i (1853) 302. D. rigida *Hook. f. Fl. Nov. Zel.* i (1853) 303, t. 69A (*not of Raoul*). D. pentaflora *Col. in Trans. N.Z. Inst.* xvi (1884) 343. Agrostis pilosa *A. Cunn. Precur.* (1836) n. 254 (*not of A. Rich.*).

North and South Islands, Stewart Island: From the Bay of Islands southwards, but often local or absent from large districts. Sea-level to 3500 ft.

A handsome species, often attaining a large size. It is distinguished from all the forms of *D. Raoulii* by the flatter leaves, which are often softly pilose on the sheaths and margins, and by the rather smaller spikelets with a straight subulate awn, not flattened nor twisted at the base.

xxix · 2.

2. **D. ovata** *Buch. N.Z. Grasses* (1879) t. 29.—Densely tufted, forming compact yellowish-green tussocks. Culms 1½–2 ft. high, $\frac{1}{6}$ in. diam. at the base, slender, terete, glabrous or slightly pilose. Leaves shorter than the culms, few in number, slender, involute and terete, undulate above the middle and sometimes almost to the base, rigid, pale yellowish-green, narrowed upwards into long filiform undulate points; both surfaces clothed with long appressed hairs except the smooth rounded keel and the thickened margins, which are more or less glabrous, deeply and regularly grooved. Sheaths long, cylindric, closed almost to the top, glabrous or nearly so; ligule a broad rim of hairs at the mouth of the sheath. Panicle 2–4 in. long, sparingly branched, ovate, branches few, in whorls of 3, glabrous. Spikelets few, remote, rather large for the size of the plant, $\frac{1}{2}$–$\frac{2}{3}$ in. long without the awns, 4–6-flowered; pedicels long, glabrous or nearly so. Flowering glumes subequal, lanceolate, acute, 3–7-nerved, deeply 2-fid at the tip, silky at the base and sides; central awn flattened at the base and twisted. Palea nearly as long as the glume.—*Cheesem. Man. N.Z. Fl.* (1906) 885. D. teretifolia *Petrie in Trans. N.Z. Inst.* xlvi (1914) 36.

South Island: Southland—Mount Eglinton, *J. Morton;* End Peak and Mount Cleaughearn, *Crosby Smith!* The Hump, near Lake Hauroto, *J. Speden!* top of Longwood Range, *Petrie!* 2500–4500 ft.

A remarkably distinct species. It is no doubt identical with Buchanan's *D. ovata*, but it is so badly described and figured that his name barely deserves consideration.

3. **D. bromoides** *Hook. f. Fl. Nov. Zel.* i (1853) 303, t. 68A.—Densely tufted, forming tussocks 1–4 ft. high. Culms stout, often as thick as the little finger at the base, quite glabrous, leafy throughout. Leaves longer or shorter than the culms, involute, gradually narrowed into very slender almost filiform points, coriaceous, smooth, polished, deeply striate; margins smooth, often pilose with long hairs towards the base; sheaths long, pale, compressed, grooved, margins scarious; ligules reduced to a transverse band of short densely set silky hairs. Panicle short, ovate-lanceolate or ovate-oblong, contracted, densely many-flowered, 4–6 in. long; rhachis glabrous, angled; branches short, close, suberect, 1–3 in. long. Spikelets pedicelled, about $\frac{3}{4}$ in. long without the awns, rather broad, oblong or linear-oblong, 4–10-flowered, the upper flower usually imperfect. Two

4. D. rigida Raoul 1844 p. 116. Ann. Sci. Nat.

outer glumes about $\frac{2}{3}$ the length of the spikelet, unequal, lanceolate, obscurely 3–5-nerved. Flowering glumes clothed in their lower half with long silky hairs on the margins and back, 7–9-nerved, sharply 2-fid at the tip, the divisions often produced into short awns; intermediate awn from between the divisions, $\frac{1}{2}$–$\frac{3}{4}$ in. long, stout, erect or spreading, convex or slightly flattened at the base, rarely twisted. Palea linear-oblong, 2-nerved, ciliate on the nerves.—*Handb. N.Z. Fl.* (1864) 332; *Cheesem. Man. N.Z. Fl.* (1906) 885. Bromus antarcticus *Hook. f. Fl. Antarct.* i (1844) 97, t. 54. Danthonia antarctica *var.* elata *Hook. f. Fl. Nov. Zel.* i (1853) 302.

North Island: In various localities near the sea, rare and local. Auckland—Between Whangaroa and Mangonui, *T. F. C.*; Bay of Islands, *T. Kirk! T. F. C.*; Maunganui Bluff, *Petrie!* Wellington—Hills near Wellington, *Stephenson*; near Cape Palliser, *Buchanan!* Auckland and Campbell Islands: Abundant on the hills, *Hooker, Buchanan! T. Kirk!* See Subl. Is. 2. 475.

I am still doubtful whether the Auckland and Campbell Islands plant, originally described by Hooker as *Bromus antarcticus*, has been rightly merged by him with the North Island *D. bromoides*. It is much larger and stouter, with larger spikelets containing more numerous florets, and often forms tussocks 3–4 ft. high, attaining a size almost equal to that of *D. Raoulii*, whereas the typical *bromoides* is rarely more than 18 in. high. If further investigation should prove it to be distinct, there seems to be no reason why Hooker's name of *D. antarctica* (Fl. Nov. Zel. i, 302) should not be reapplied to it, for although he also included the plant now known as *D. Cunninghamii* it was as a separate variety, the Auckland Islands plant being evidently treated as the type of the species.

4. **D. Raoulii** *Steud. Syn. Pl. Glum.* (1855) 246.—Densely tufted, forming large brownish-green tussocks 2–5 ft. high. Culms stout or slender, smooth, often branched at the base. Leaves numerous, longer or shorter than the culms, variable in width at the base, gradually narrowed into long filiform points, strongly involute and rush-like when dry, coriaceous, smooth and polished on the back, ribbed on the inner face; margins smooth, glabrous or pilose just above the ligules; sheaths brownish, much broader than the blade, often lax and scarious towards the base, coriaceous above, glabrous or sparsely pubescent; ligules reduced to a transverse band of short dense hairs. Panicle variable in size, 4–18 in. long, lax; branches few or many, divided, slender, filiform, smooth and glabrous; pedicels long, often silky towards the tips. Spikelets $\frac{1}{2}$–$\frac{3}{4}$ in. long without the awns, 4–10-flowered. Two empty glumes unequal, from $\frac{1}{2}$–$\frac{2}{3}$ the length of the spikelet, ovate-lanceolate, the lower 3-nerved, the upper 5-nerved, the lateral nerves usually short. Flowering glumes with long silky hairs at the base and on the margins for $\frac{1}{2}$ their length or more, often also fringed on the lower part of the back, deeply bifid at the tip, the divisions usually produced into short scabrid awns, 7–9-nerved; central awn long, $\frac{1}{3}$–$\frac{1}{2}$ in., straight or recurved, flattened and usually twisted at the base. Palea rather shorter than the glume, 2-nerved, silky on the nerves.—*Buch. N.Z. Grasses* (1879) t. 30; *Cheesem. Man. N.Z. Fl.* (1906) 886; *Ill. N.Z. Fl.* ii (1914) t. 226. D. rigida *Raoul Choix* (1846) 12; *Hook. f. Fl. Nov. Zel.* i (1853) 303, t. 69A (*not of Steud.*).

Trans. 43: 368.

Var. **flavescens** *Hack. MSS.*—More robust; culms often $\frac{1}{2}$ in. diam. at the base. Leaves broader; sheaths sometimes $\frac{1}{2}$–$\frac{3}{4}$ in. across; lamina $\frac{1}{4}$–$\frac{1}{3}$ in. at the base. Spikelets rather larger.—D. flavescens *Hook. f. Handb. N.Z. Fl.* (1864) 332; *Buch. N.Z. Grasses* (1879) t. 32. Trans 43 : 368

Var. **Cheesemanii** *Hack. MSS.*—Culms slender. Leaves pale-green, complicate, compressed, not terete and rush-like when dry, strongly ribbed on both surfaces; margins and ribs on the back rough and scabrid. Panicle-branches scaberulous. Awn rarely twisted.

var. teretifolia petrie Trans. 54: 1923: 571

D. flav. var cheesemanii (Hack & Cheesem) Zotov

D. rigida var. teret. (Petrie) Zotov.

North and South Islands, Stewart Island: From Mount Hikurangi and Mount Egmont southwards, abundant in hilly and mountain districts. Sea-level to 5500 ft. "*Snow-grass.*" Var. *Cheesemanii:* Open forests near the source of the Takaka River, Nelson, altitude 3000 ft., *T. F. C.;* Endeavour Inlet, Queen Charlotte Sound, *J. H. Macmahon!*

A most abundant plant in the elevated hilly districts of the South Island, often forming the major portion of the vegetation over large areas. I agree with Professor Hackel in considering *D. flavescens* to be simply a broad-leaved state of *D. Raoulii;* in point of fact the two forms graduate into one another so insensibly that it is impossible to draw a strict line of demarcation between them.

Var. *Cheesemanii* is well distinguished by its scabrid leaves, which are compressed and plicate, and prominently nerved. It may prove to be a separate species.

5. **D. crassiuscula** *T. Kirk in Trans. N.Z. Inst.* xvii (1885) 224.—Culms tufted, forming lax tussocks, stout, strict, erect, leafy, 6–18 in. high. Leaves shorter or rarely longer than the culms, distichous, rigid and coriaceous, curved, gradually narrowed to the tips but not drawn out into filiform points, strongly involute, compressed, smooth and polished on the back, with numerous thick veins in front; margins smooth; sheaths stout, much broader than the blade, smooth, grooved; margins thinner and scarious; ligules reduced to an obscure band of short stiff hairs. Panicle short, lax, broadly ovate, 1½–3 in. long; branches few, spreading, 2–3-spiculate, and with the rhachis more or less silky-pubescent. Spikelets about ⅓ in. long without the awns, 4–7-flowered. Two outer glumes unequal, lanceolate, 3–5-nerved, the longer frequently ⅘ the length of the entire spikelet. Flowering glumes densely silky at the base, and with long silky hairs on the margins and back for about ½ their length, 7–9-nerved, the nerves connected by transverse veins at about the level of the awn, tip deeply bifid, the lobes pointed but not awned; central awn ¼–⅓ in. long, flat at the base and often twisted. Palea slightly shorter than the glume.—*Cheesem. Man. N.Z. Fl.* (1906) 887.

South Island: Probably abundant in high mountain districts throughout. Canterbury—Mountains above the Broken River, *T. F. C.;* Upper Waimakariri, *Cockayne!* Westland—Kelly's Hill, *Petrie!* Otago—Mount Arnould, Hector Mountains, *Petrie!* mountains above Lake Harris, Longwood Range, *T. Kirk!* Stewart Island: Mount Anglem, *T. Kirk!* 3500–6000 ft.

Closely allied to *D. Raoulii*, but a smaller and proportionately stouter plant, with shorter compressed leaves not drawn out into filiform points, much smaller panicles with silky-pubescent branches, smaller spikelets with longer outer glumes, and with the nerves of the flowering glumes connected by transverse veinlets.

6. **D. pungens** *Cheesem. Man. N.Z. Fl.* (1906) 887.—Culms densely tufted, branched at the base, forming irregular patches about 1 ft. across, smooth, slender, rigid, 2–6 in. high. Leaves mostly at the base of the culms and much shorter than them, distichous, 1½–3 in. long, about $\frac{1}{10}$ in. broad at the base, gradually tapering upwards into a pungent point, strict, erect, rigid and coriaceous, involute, almost equitant at the base, finely striate, glaucous; margins thickened, smooth; sheaths compressed, grooved; ligules reduced to a narrow band of short white hairs. Panicle small, lax, ovate, 1–1½ in. long, of 3–8 spikelets; branches few, slender, silky. Spikelets about ⅓ in. long without the awns, 3–5-flowered. Two outer glumes slightly unequal, almost as long as the spikelet, lanceolate, membranous, 3–5-nerved. Flowering glumes silky at the base, and equally clothed with silky hairs for ½ their length, 7–9-nerved, deeply 2-fid at the apex, the lobes lanceolate, acute but not awned; central awn flattened

and usually spirally twisted at the base. Palea almost as long as the flowering glume, ciliate on the nerves and silky on the margins near the base.

STEWART ISLAND: Very abundant above the scrub-line on all the mountains visited, *T. Kirk! Cockayne, F. G. Gibbs,* and others. Apparently restricted to the island.

A remarkably distinct and curious little plant, at once recognized by the flattened rigid and pungent pointed leaves.

7. **D. australis** *Buch. N.Z. Grasses* (1879) t. 31.—Forming extensive patches on alpine or subalpine slopes. Culms much branched at the base, prostrate or decumbent and covered with the remains of the old leaves, ascending and then erect above, quite glabrous, 6–18 in. high. Leaves numerous towards the base of the culms and much shorter than them, distichous, imbricate, strict, rigid, erect or curved to one side, 2–6 in. long, about $\frac{1}{40}$ in. broad, closely involute, smooth and polished, acute at the tip; sheaths short, closely overlapping, tight, much broader than the blade; ligules reduced to a line of silky hairs. Panicle small, lax, 1–2 in. long, of 3–8 spikelets on slender capillary silky-pubescent branches. Spikelets $\frac{1}{2}$–$\frac{2}{3}$ in. long, 4–7-flowered. Two outer glumes slightly unequal, lanceolate, acuminate, membranous, 5–7-nerved, from $\frac{4}{5}$ to $\frac{5}{6}$ the length of the spikelet. Flowering glumes silky at the base and with the back and margins fringed with silky hairs for more than $\frac{1}{2}$ their length, deeply 2-fid at the tip, the divisions produced into short scabrid awns, 7–9-nerved; central awn $\frac{1}{3}$–$\frac{1}{2}$ in. long, slender, flat and spirally twisted at the base. Palea shorter than the glume, linear-oblong.—*Cheesem. Man. N.Z. Fl.* (1906) 888; *Ill. N.Z. Fl.* ii (1914) t. 227. *D. Raoulii* var. australis *Buch. in Trans. N.Z. Inst.* iv (1872) 224.

SOUTH ISLAND: Not uncommon on the mountains of Nelson, Canterbury, and Westland, altitude 3500–6000 ft. "*Carpet-grass*"; "*Hassock-grass.*"

A well-marked species, often covering acres on the higher mountains of Nelson and North Canterbury, usually affecting steep slopes. After the melting of the snow in early summer, which usually leaves the culms and leaves pointing downhill, these slopes are most slippery and treacherous to cross. There is a specimen in Mr. Petrie's herbarium marked "Campbell Island, J. Buchanan."

8. **D. oreophila** *Petrie in Trans. N.Z. Inst.* xxvii (1895) 406.—Culms densely tufted, much branched at the base, slender, erect, leafy, 6–12 in. high. Leaves subdistichous, 2–5 in. long by $\frac{1}{12}$–$\frac{1}{10}$ in. broad at the base, tapering upwards into long slender points, flat or involute, grooved, margins scaberulous above; ligules reduced to a transverse band of short dense hairs with a few longer ones on each side. Panicle about $1\frac{1}{2}$ in. long, broadly ovate, lax, of 4–8 spikelets; branches few, capillary, glabrous or with a tuft of silky hairs at the forks. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. long, 4–7-flowered. Two outer glumes slightly unequal, acute, membranous, 3–5-nerved, about $\frac{4}{5}$ the length of the spikelet. Flowering glumes densely silky at the base and on the margins for $\frac{1}{2}$ their length, a few silky hairs also along the lower part of the back, membranous, 9-nerved, deeply 2-fid at the tip, the lobes broad, acute but not awned; intermediate awn from between the lobes, about $\frac{1}{8}$ in. long, reflexed, flattened at the base but not twisted. Palea linear-oblong, 2-nerved, ciliate on the nerves.—*Cheesem. Man N.Z. Fl.* (1906) 888. D. pallida *Petrie in Trans. N.Z. Inst.* xxvi (1894) 271 (*not of R. Br.*).

D penicillata (Labill.) Palisot de Beauvois 1812 p. 192.
Arundo penicillata Labill. 1804.

Petrie, cumberl. Trans 73 234

(flavescens. Var. **elata** (*Petrie*) *in Trans. N.Z. Inst.* xlv (1913) 274—Much taller and stouter than the type, 18–20 in. high, forming dense tussocks. Panicles larger, reddish when young.

South Island: Canterbury—Candlestick Range, *Cockayne!* Westland—Kelly's Hill, *Petrie!* 3500–4500 ft. Var. *elata:* Sealey Range, Hooker Valley, 4000–5000 ft., *Petrie! T. F. C.*

Allied to *D. australis*, but much less rigid and not so densely tufted, with broader flatter leaves; the panicle-branches are nearly glabrous and the spikelets smaller and paler; the terminal lobes of the flowering glume are broader and not awned; and the central awn is shorter and not twisted at the base. It is still nearer to *D. planifolia.*

9. **D. planifolia** *Petrie in Trans. N.Z. Inst.* xxxiii (1901) 328.—Culms apparently not tufted, sparingly branched at the base, erect, slender, glabrous, 9–14 in. high. Leaves chiefly at the base of the culms and much shorter than them, 2–5 in. long, $\frac{1}{10}$–$\frac{1}{6}$ in. broad, gradually tapering to an acute point, flat, smooth, striate; sheaths rather lax, pale, grooved, the uppermost much longer than the blade; ligules a transverse band of long soft hairs. Panicle short, lax, ovate, 1½–2 in. long, of 6–12 spikelets; branches few, slender, silky with long hairs. Spikelets rather large, about ½ in. long, pale-green tinged with purple, 3–5-flowered. Two outer glumes subequal, lanceolate, acuminate, membranous, 3–5-nerved, about as long as the spikelet. Flowering glumes densely silky at the base, and with long silky hairs along the margins and back for ½ their length, deeply 2-fid at the apex, the lobes acute or acuminate, but scarcely awned, 7–9-nerved; intermediate awn from between the lobes, ⅓–½ in. long, more or less flattened and twisted at the base. Palea linear-oblong, deeply bifid, 2-nerved, nerves ciliate.—*Cheesem. Man. N.Z. Fl.* (1906) 889.

South Island: Otago—Clinton Saddle, to the west of Lake Te Anau, *Petrie!* 2500 ft.

This only differs from *D. oreophila* in the flatter and more membranous leaves, larger spikelets with longer empty glumes, and longer awn usually twisted at the base. I have seen few specimens, and these all from one locality. It is not improbable that further investigations may reduce the plant to a variety of *D. oreophila.*

10. **D. pilosa** *R. Br. Prodr.* (1810) 177.—Culms tufted, slender, glabrous or sparingly pilose, leafy at the base, 1–2 ft. high, rarely more. Leaves usually much shorter than the culms, narrow, often setaceous, involute or rarely flat, glabrous or pilose with spreading hairs; sheaths narrow, grooved, pilose or glabrous; ligules reduced to a transverse band of long soft hairs. Panicle 1–4 in. long, usually narrow and contracted, sometimes racemiform; branches short, erect. Spikelets about ½ in. long, 4–8-flowered. Two outer glumes exceeding the flowering glumes, subequal, lanceolate, acute, membranous, 7-nerved. Flowering glumes 7–9-nerved, deeply 2-lobed at the tip, the lobes produced into fine awns as long or longer than the glume, central awn from between the lobes, exserted beyond the spikelet, flattened and spirally twisted and often dark-coloured at the base, a tuft of silky hairs at the base of the callus or pedicel of the glume, a tuft on the margin on each side above the callus, sometimes connected by hairs on the back, and another marginal tuft on each side opposite to the base of the lobes, the sides and back between usually glabrous. Palea broad, obtuse or shortly bifid at the tip.—*Hook. f. Fl. Nov. Zel.* i (1853) 303; *Fl. Tasm.* ii (1860) 120; *Benth. Fl. Austral.* vii (1878) 594; *Buch. N.Z. Grasses* (1879) t. 33; *Cheesem. Man. N.Z. Fl.* (1906) 890. D. semiannularis *var.* pilosa *Hook. f. Handb. N.Z. Fl.* (1864) 333. D. nervosa *Col. in Trans. N.Z. Inst.* xxviii (1896) 612 (*not of Hook. f.*).

Arundo penicillata Labill. 1804, 26–34. 1855. 334
Danthonia " GRAMINEAE.) F.N.Z. [Danthonia.

Var. **racemosa** *Buch. N.Z. Grasses* (1879) t. 33(2)B.—Culms very slender, drooping. Panicle reduced to a slender raceme of 4–10 almost sessile spikelets.

NORTH AND SOUTH ISLANDS, STEWART ISLAND: Abundant throughout. Sea-level to 4000 ft.

D. pilosa is technically distinguished from *D. semiannularis* by the absence of the transverse ring of hairs on the flowering glume just below the lobes. In the typical state this ring is reduced to a small tuft of hairs on each margin of the glume, the sides and back between the tufts being quite glabrous. But occasionally there are a few hairs on the back of the glume as well, and sometimes these become so numerous as almost to form a transverse ring, thus breaking down the distinction between the two species. *D. pilosa* is also found in Australia, ranging from Queensland to Tasmania and West Australia.

(Labill)

11. **D. semiannularis** *R. Br. Prodr.* (1810) 177.—Very variable in size, usually 1–2 ft. high, but often dwarfed to a few inches, and sometimes attaining 3 ft. Culms tufted, slender, smooth, glabrous or sparingly pilose. Leaves shorter than the culms, narrow, flat or involute, often almost setaceous; sheaths grooved, glabrous or pilose with long spreading hairs; ligules reduced to a narrow transverse band of soft silky hairs, those on the outside the longest. Panicle 1–4 in. long, usually compact and more or less contracted; branches few, short, erect. Spikelets $\frac{1}{4}$–$\frac{1}{2}$ in. long without the awns, 3–8-flowered. Two outer glumes exceeding the flowering glumes, subequal, lanceolate, acute, membranous, 5–7-nerved. Flowering glumes 7–9-nerved, deeply 2-lobed at the tip, the lobes produced into fine awns often as long as the glume, central awn from between the lobes, usually exserted beyond the spikelet, flat and spirally twisted at the base, a ring of short silky hairs around the glume at the base, and a transverse ring of longer hairs (often arranged in separate tufts) just below the base of the lobes. Palea exceeding the base of the awn, narrow-oblong.—*Hook. f. Fl. Nov. Zel.* i (1853) 304; *Handb. N.Z. Fl.* (1864) 333; *Benth. Fl. Austral.* vii (1878) 595; *Buch. N.Z. Grasses* (1879) t. 34; *Cheesem. Man. N.Z. Fl.* (1906) 890. D. unarede *Raoul Choix* (1846) 11, t. 4. D. gracilis *Hook. f. Fl. Nov. Zel.* i (1853) 303, t. 69B.

CKn. N.Z.J. Ag. 23 (1902) 146

Var. **setifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 304.—Culms more densely tufted. Leaves very narrow, terete from the strongly involute margins, strict, wiry, erect. Panicle smaller, with fewer spikelets. Flowering glumes less copiously silky, the hairs of the upper transverse band shorter.—D. semiannularis *var.* alpina *Buch. in Trans. N.Z. Inst.* iv (1872) 225; *N.Z. Grasses* (1879) t. 34(2)A.

Var. **nigricans** *Petrie in Trans. N.Z. Inst.* ~~xxxvi~~ (1914) 37.—Differs from var. *setifolia* in the shorter spikelets, smaller florets, and in the empty glumes being blackish-brown with a scarious margin.

NORTH AND SOUTH ISLANDS, STEWART ISLAND, CHATHAM ISLANDS: Abundant throughout, var. *setifolia* in mountainous situations, ascending to over 5000 ft. Var. *nigricans:* Mount Hector (Tararua Range); Waimangaroa, Millerton, Burnett's Face, and other localities near Westport; Lake Harris (Lake County), *Petrie!*

Also abundant throughout the whole of temperate Australia. In New Zealand this species and *D. pilosa* are now largely sown as pasture-grasses, especially in the northern part of the colony. On stiff clay soils they are far more permanent than most introduced species, and might with advantage be substituted for them.

12. **D. Buchanani** *Hook. f. Handb. N.Z. Fl.* (1864) 333.—Culms tufted, slender, smooth, quite glabrous, 3–12 in. high. Leaves mostly at the base of the stems and much shorter than them, strict, erect, wiry, very narrow, involute, filiform or nearly so; sheaths pale, glabrous, deeply grooved; ligules reduced to a band of short white hairs. Panicle small, contracted, $\frac{3}{4}$–2 in. long, of 4–12 spikelets; branches few, scaberulous. Spikelets pale-

(D. nigricans (Pet.) Calder Trans. Linn. Soc. Bot. 51: 1937: p. 8.

green, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 3–5-flowered. Two outer glumes exceeding the flowering glumes and often the awns as well, subequal, oblong-lanceolate, acute, 3–5-nerved. Flowering glumes 7–9-nerved, 2-lobed at the tip, the lobes produced into short awns, central awn from between the lobes, short, hardly equalling the length of the glume, straight or bent, not at all or very obscurely twisted at the base, a tuft of silky hairs at the base of the glume and on the margins higher up, usually connected by straggling hairs on the back and sides, forming an indistinct transverse ring. Palea oblong, 2-nerved; nerves ciliate.—*Cheesem. Man. N.Z. Fl.* (1906) 891.

Var. **tenuis** *Petrie in Trans. N.Z. Inst.* xlvi (1914) 37.—Leaves setaceo-filiform, shorter than the culms. Panicle linear. Spikelets shorter and narrower than the type!

SOUTH ISLAND: Canterbury—Upper Waimakariri, *T. Kirk! Petrie! T. F. C.;* Mount Torlesse, *Petrie!* Mount Arrowsmith, *Cockayne.* Otago—Lake district, *Hector* and *Buchanan!* Kurow, Mount Ida, Macrae's, Pembroke, Bendigo, Lake Te Anau, *Petrie!* Southland, *Crosby Smith.* 1000–3000 ft. Var. *tenuis:* Not uncommon in the

grooved. Panicle small, ovate or oblong, $\frac{3}{4}$–$1\frac{3}{4}$ in. long, of 6–15 spikelets; branches few, short, pubescent. Spikelets $\frac{1}{5}$–$\frac{1}{6}$ in. long, 2–3-flowered. Two outer glumes subequal, exceeding the flowering glumes and awns, oblong-lanceolate, acute. Flowering glumes very shortly bifid at the top, intermediate awn short, straight, about $\frac{1}{3}$–$\frac{1}{4}$ the length of the glume; two short tufts of hairs on each side near the margin of the glume, with a tuft at the base of the glume, and a few scattered hairs across the back.—*Handb. N.Z. Fl.* (1864) 333 (*but not of Buch. N.Z. Grasses*, t. 36A, *or of Cheesem. Man. N.Z. Fl.* (1906) 892). T.N.Z.I. 2?: 587 & 44: 108.

NORTH ISLAND: Ruahine Range, *W. Colenso!* Tararua Range, *B. C. Aston!* near Waiouru, *Petrie!*

As remarked by Hooker, this is not at all a characteristic species of *Danthonia*, differing in the very short erect awn, which is never twisted at the base, and in the much less evident lateral awns.

24. **ELEUSINE** Gaertn. 1788

Annual or perennial grasses. Leaves long, flat or folded, firm or membranous. Spikelets 3- to many-flowered, laterally compressed, sessile and densely imbricate in 2 rows on one side of a flattened rhachis, forming linear spikes; spikes digitately arranged or irregularly scattered; rhachilla disarticulating above the outer glumes. Two outer glumes shorter than the flowering glumes, persistent, empty, unequal, keeled, obtuse or mucronate, membranous, 3–5-nerved. Flowering glumes similar to the outer glumes, 3-nerved at the base. Palea shorter than the glumes, complicate and 2-keeled. Lodicules 2, minute. Stamens 3; anthers short. Styles short, distinct; stigmas plumose. Grain broadly oblong, grooved; pericarp lax, hyaline.

Species 6, most plentiful in tropical Asia and Africa, the one found in the New Zealand area a weed in all warm countries.

24. **ELEUSINE** Gaertn. 1766

Annual or perennial grasses. Leaves long, flat or folded, firm or membranous. Spikelets 3- to many-flowered, laterally compressed, sessile and densely imbricate in 2 rows on one side of a flattened rhachis, forming linear spikes; spikes digitately arranged or irregularly scattered; rhachilla disarticulating above the outer glumes. Two outer glumes shorter than the flowering glumes, persistent, empty, unequal, keeled, obtuse or mucronate, membranous, 3–5-nerved. Flowering glumes similar to the outer glumes, 3-nerved at the base. Palea shorter than the glumes, complicate and 2-keeled. Lodicules 2, minute. Stamens 3; anthers short. Styles short, distinct; stigmas plumose. Grain broadly oblong, grooved; pericarp lax, hyaline.

Species 6, most plentiful in tropical Asia and Africa, the one found in the New Zealand area a weed in all warm countries.

1. **E. indica** *Gaertn. Fruct.* i, 8.—Annual. Culms tufted, erect or decumbent at the base, branched, stout or slender, compressed, quite glabrous, 9–24 in. high. Leaves numerous, distichous, 4–9 in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad, flat, rather flaccid, acuminate; sheaths compressed, pale, margins ciliate; ligules almost obsolete. Spikes rather slender, straight, $1\frac{1}{2}$–3 in. long, usually 3–6 in a terminal umbel, generally one inserted lower down; rhachis smooth or pubescent at the base. Spikelets about $\frac{1}{6}$ in. long, densely imbricated, 3–6-flowered. Two outer glumes unequal, the lower small, 1-nerved; the upper 3–5-nerved. Flowering glumes much larger, ovate when spread out, acute, 3-nerved. Grain oblong; pericarp very lax and membranous, enclosing the rugose seed.—*Benth. Fl. Austral.* vii (1878) 615; *Cheesem. in Trans. N.Z. Inst.* xx (1888) 176; *Man. N.Z. Fl.* (1906) 892.

KERMADEC ISLANDS: Lower portions of Sunday Island and on Meyer Island, plentiful and apparently indigenous, *T. F. C., W. R. B. Oliver!* NORTH AND SOUTH ISLANDS: Naturalized near Auckland, *Sinclair*, and at Westport, *W. Townson!*

25. ARUNDO Linn.

Tall perennial reed-like grasses. Culms densely tufted, stout, almost woody at the base. Leaves flat. Spikelets numerous, laterally compressed, 2–7-flowered, arranged in large decompound panicles; rhachilla disarticulating above the two outer glumes and between the flowering glumes. Two outer glumes persistent, empty, subequal, lanceolate, acuminate, membranous, glabrous. Flowering glumes ovate-lanceolate, 3–5-nerved, pilose along the back and towards the base with long silky hairs, 2-fid at the apex, with a cuspidate point or awn from between the lobes. Palea short, hyaline, 2-nerved. Lodicules 2, obovate. Stamens 3. Ovary glabrous; styles distinct; stigmas plumose. Grain oblong, free within the flowering glume and palea.

A small genus of 10 or 12 species, dispersed through most tropical and warm-temperate regions. The two species found in New Zealand are endemic.

Two outer glumes including the flowering glumes and their awns.
Flowering glumes deeply bifid, the divisions long and bristle-pointed .. .. 1. *A. conspicua.*

Two outer glumes shorter than the awns of the flowering glumes.
Flowering glumes not so deeply bifid, the divisions scarcely bristle-pointed .. .. 2. *A. fulvida.*

1. **A. conspicua** *Forst. f. Prodr.* (1786) n. 48.—Forming huge dense tussocks with numerous long curving leaves. Culms 3–10 ft. high, as thick as the finger at the base, slender, erect, smooth, hollow. Leaves long, narrow, coriaceous, flat or involute, strongly nerved, smooth or scabrid along the margins and on the nerves of the upper surface; sheaths long, smooth; ligules reduced to a transverse band of short stiff hairs. Panicle very handsome, silky-white or yellowish-white, copiously branched, 1–2 ft. long; branches drooping, very many-spiculate, smooth or pilose-scabrid. Spikelets 1–3-flowered, on short capillary pedicels. Two outer glumes subequal, $\frac{3}{4}$–$1\frac{1}{2}$ in. long, longer than or at least equalling the awns of the flowering glumes, narrow-lanceolate, gradually tapering into long acuminate points, membranous, 1-nerved, usually with a very short lateral nerve on each side near the base. Flowering glumes hyaline, 3-nerved, lower half densely clothed with long silky hairs, deeply 2-fid at the tip, the

divisions produced into bristle-like awns; central awn from between the divisions, long, slender, scabrid. Palea shorter than the glume, pubescent on the nerves.—*Hook. f. Fl. Nov. Zel.* i (1853) 299; *Handb. N.Z. Fl.* (1864) 341; *Buch. N.Z. Grasses* (1879) t. 27; *Bot. Mag.* t. 6232; *Cheesem. Man. N.Z. Fl.* (1906) 893. A. australis *A. Rich. Fl. Nouv. Zel.* (1832) 121; *A. North and South Islands, Stewart Island, Chatham Islands: Abundant throughout in damp lowland situations. *Toetoe-Kakaho;* culms of, *Kakaho.*

The largest grass in the colony, forming a very characteristic feature of the vegetation in all swampy tracts, river-banks, sandhills, &c. The culms were formerly largely used by the Maoris for lining their meeting-houses, and were often dyed in elaborate patterns.

2. **A. fulvida** *Buch. in Trans. N.Z. Inst.* vi (1874) 242.—Habit and general appearance of *A. conspicua*, but rather smaller, culms seldom more than 6 ft. high. Panicle pale-fulvous, usually more compact, broader and more erect, 1–2 ft. long. Spikelets 1–3-flowered. Two outer glumes shorter, $\frac{1}{3}$–$\frac{2}{3}$ in. long, not drawn out into such long points, and usually considerably shorter than the awns of the flowering glumes. Flowering glumes not so deeply bifid at the tip, the divisions scarcely awned; central awn exserted beyond the outer glumes.—*Buch. N.Z. Grasses* (1879) t. 28; *Cheesem. Man. N.Z. Fl.* (1906) 894. A conspicua *var.* fulvida *T. Kirk in Trans. N.Z. Inst.* x, App. (1878) 43.

North and South Islands: From the Bay of Islands to Foveaux Strait, not nearly so abundant as *A. conspicua.*

This does not differ from *A. conspicua* except in the outer glumes not including the awns of the flowering glumes, and in the terminal lobes of the flowering glumes being shorter and scarcely awned. But these differences are easily recognized and well marked, and probably the species should be maintained.

26. **TRIODIA** R. Br.

Perennial grasses, of very various habit. Leaves narrow, rigid. Spikelets 2- to many-flowered, arranged in a lax or narrow panicle; rhachilla disarticulating above the 2 outer glumes and between the flowering glumes. Two outer glumes longer or shorter than the flowering glumes, somewhat rigid, empty, keeled, acute, awnless. Flowering glumes more or less imbricated, rounded on the back at the base, coriaceous or chartaceous, often hairy on the margins and callus, 3-nerved, 3-lobed or 3-toothed at the apex, the lobes equal or the central one produced into a short awn or mucro. Palea broad, thin, with 2 almost marginal keels. Lodicules 2. Stamens 3. Styles short, distinct; stigmas plumose. Grain usually compressed on the back, free within the flowering glume and palea.

Species from 25 to 30, mostly in the temperate regions of both hemispheres, a few in tropical America. The New Zealand species belong to the subgenus *Rhombolytrum,* characterized by the lateral teeth of the flowering glume being very small or almost obsolete, the middle tooth being also small and mucronate. It contains a few Chilian and North American species in addition to the five found in New Zealand, all of which are endemic.

Densely matted; culms 1–3 in. Panicle often reduced to a single spikelet. Outer glumes ovate. Flowering glumes silky on the margins, distinctly 3-toothed at the apex .. .. .. 1. *T. exigua.*

Culms tufted, 2–6 in. Panicle of 8–12 spikelets. Outer glumes lanceolate. Flowering glumes sparsely silky, 5–7-nerved, minutely 3-toothed at the apex .. .. 2. *T. pumila.*
Culms tufted, 4–12 in. Panicle of 6–16 spikelets. Outer glumes oblong-lanceolate. Flowering glumes silky at the base, and with two tufts on the margin on each side.. .. .. 3. *T. Thomsoni.*
Culms tufted, 2–4 in. Panicle of 6–15 spikelets. Outer glumes broadly ovate. Flowering glumes glabrous, 9-nerved, obscurely 3-toothed or irregularly erose at the apex .. .. 4. *T. australis.*
Culms tufted, 2½–5 in. Panicle of 6–16 spikelets. Outer glumes oblong, obtuse. Flowering glumes glabrous, ovate, 5-nerved, minutely 3-toothed or irregularly erose at the tip .. .. 5. *T. macquariensis.*

Danthonia Zotov. Trans 73: 234.

1. **T. exigua** (*T. Kirk*) *in Trans. N.Z. Inst.* xiv (1882) 378.—Small, densely matted, forming a compact sward. Rhizomes long, creeping, branched. Culms erect from the rhizome, slender, wiry, glabrous, 1½–4 in. high. Lower leaves reduced to sheathing scales; upper shorter than the culms, ½–2 in. long, very narrow, convolute, filiform, rigid, erect or curved, acute or almost pungent at the tip, quite glabrous; sheaths closely appressed, pale, membranous, grooved; ligules reduced to a line of short stiff hairs. Panicle frequently reduced to a single spikelet, sometimes 2–3, rarely as many as 4–5; pedicels short, slender, minutely scaberulous. Spikelets about ⅕ in. long, ovoid-oblong, 2–4-flowered. Two outer glumes subequal, as long as the flowering glumes or very slightly shorter than them, concave, ovate, subacute, rigid, the lower one 5-nerved, the upper 7-nerved. Flowering glumes broadly ovate, silky on the margins and back towards the base, minutely scaberulous above, 9-nerved, shortly 3-toothed at the apex, the middle tooth mucroniform, not much longer than the lateral teeth. Palea broad, ciliate on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 895. Danthonia pauciflora *Buch. N.Z. Grasses* (1879) t. 36B (*not of R. Br.*).

South Island: Nelson—Clarence Valley, *T. F. C.* Canterbury—Upper Waimakariri and Broken River, *J. D. Enys! T. Kirk! Cockayne! T. F. C.*; Mount Peel, *H. H. Allan!* Otago—Not uncommon in the dry plains of the central and north-western portions of the district, *Petrie!* 500–3000 ft.

A curious little species, with much of the habit of small states of *Zoysia pungens.*

*D. Kirkii Zotov.

2. **T. pumila**, *Hack. MSS.*—Culms tufted, slender, glabrous, much branched at the base, 2–8 in. high. Leaves shorter than the culms, very narrow, involute, filiform, strict, erect, 1–2 in. long; sheaths pale, membranous, deeply grooved, glabrous or sparingly pilose with long soft hairs; ligules reduced to a transverse ring of hairs. Panicle ½–1 in. long, strict, erect, much contracted, of 3–15 spikelets; branches very short, erect, pubescent. Spikelets ⅙–⅕ in. long, lanceolate, 2–3-flowered. Two outer glumes exceeding the flowering glumes, subequal, lanceolate, acute or subacute, 3–5-nerved. Flowering glumes broadly ovate, sparsely silky-pilose on the margins and back, faintly 5–7-nerved, minutely 3-toothed at the apex, the central tooth mucroniform. Palea bifid at the tip, 2-keeled, ciliolate on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 896. Atropis pumila *T. Kirk in Trans. N.Z. Inst.* xiv (1882) 379.

South Island: Canterbury—Upper Waimakariri and Broken River, *T. Kirk! T. F. C.*; Mount Peel, *H. H. Allan!* mountains near Lake Tekapo, *T. F. C.* Otago—Not uncommon in mountainous districts, *Buchanan! Petrie! T. Kirk! B. C. Aston!* Altitudinal range usually from 2000 to 5000 ft., but descending to sea-level in the south of Otago.

Hebe 3 See Zotov.

* = T. pumila (Kirk) Hack. ex Cheesem.
= atropis pumila Kirk
non. D. pumila Hees 1841.

Referred to *Atropis* by Mr. Kirk, but clearly a *Triodia*, and closely allied to the following species, from which it differs in the longer and narrower spikelets, narrow outer glumes, and silky flowering glumes, which are distinctly though minutely 3-toothed at the apex.

3. **T. Thomsoni** *Petrie in Trans. N.Z. Inst.* xliv (1912) 188.—Culms slender, tufted, branched at the base, quite glabrous, 4–12 in. high. Leaves much shorter than the culms, involute, filiform, quite smooth and glabrous; sheaths pale, grooved; ligules reduced to a band of silky hairs. Panicle small, erect, contracted, ½–1½ in. long, of 6–16 spikelets; branches few, short, pubescent. Spikelets greenish-white, small, narrow, 3–7-flowered. Two outer glumes usually exceeding the flowering-glumes and awns, subequal, oblong-lanceolate, acute, 3–5-nerved. Flowering glumes short and broad, ovate, 7–9-nerved, very shortly bifid at the tip, central awn from between the lobes, very short, ⅙–⅛ the length of the glume, not twisted at the base, a tuft of silky hairs at the base of the glume, and two small marginal tufts (sometimes confluent) on each side higher up, back of glume glabrous. Palea oblong, shorter than the glume.—Danthonia Thomsoni *Buch. N.Z. Grasses* (1879) t. 36 (2). Danthonia nuda *Cheesem. Man. N.Z. Fl.* (1906) 892 (*not of Hook. f.*).

South Island: Nelson—Mount Arthur Plateau, *T. F. C.* Marlborough—Endeavour Inlet, *J. H. Macmahon!* Canterbury—Broken River basin, *Petrie! T. F. C.*; Poulter River, *Cockayne!* Lake Tekapo, *T. F. C.* Otago—Common in dry places in the eastern and central portions of the district, *Buchanan! Petrie!*

In the first edition of this book I confounded this species with *Danthonia nuda*, a plant with which I was not then acquainted and which has proved to be altogether distinct.

4. **T. australis** *Petrie in Trans. N.Z. Inst.* xxii (1890) 442.—Culms densely tufted, much branched at the base, erect or spreading, quite glabrous, leafy below, 2–4 in. high. Leaves usually shorter than the culms, narrow, involute, filiform, deeply striate; sheaths broad, grooved, pale; ligules reduced to a narrow band of short white hairs with a longer tuft on each side. Panicle small, strict, erect, contracted, ½–¾ in. long, of 6–15 spikelets; branches 4–6, short, pubescent. Spikelets about ⅛ in. long, 2–4-flowered. Two outer glumes rather shorter than the flowering glumes, subequal, broadly ovate, obtuse, 7-nerved; margins broad, pale. Flowering glumes very broadly ovate or rounded, glabrous, firm, 9-nerved, minutely and irregularly 3-toothed or erose at the tip. Palea broad, 2-keeled, the keels ciliolate.—*Cheesem. Man. N.Z. Fl.* (1906) 896.

Var. **mucronulata** *Hack. MSS.*—Sheaths pilose with long hairs. Spikelets 3-5-flowered, the outer glumes distinctly shorter than the flowering glumes, which are more evidently 3-toothed, the middle tooth produced into a short mucro.

South Island: Otago—Sides of mountain-streams, Clark's Diggings, Mount Cardrona, Old Man Range, Maungatua, Blue Mountains, *Petrie!* Var. *mucronulata*: Swamps in the Tasman Valley, Canterbury, *T. F. C.* 2000–5000 ft.

5. **T. macquariensis** *Cheesem. in Vascl. Fl. Macquarie Is.* (1919) 34 (*Austral. Antarct. Exped.* vol. 7, part 3).—Apparently perennial, tufted, often forming dense patches, smooth and glabrous. Culms numerous, erect or geniculate at the base, 2½–5 in. high, leafy to the base of the panicle. Leaves equalling the culms or longer than them, rather narrow, $\frac{1}{10}$–$\frac{1}{20}$ in. broad, deeply striate, quite glabrous, flat or involute, margins thickened, tips obtuse, callous; ligules broad-ovate, thin and membranous;

sheaths unusually long, much broader than the blades, sometimes as much as $\frac{1}{6}$ in. across, smooth, pale and membranous. Panicle narrow, glabrous, $\frac{3}{4}$–$1\frac{1}{2}$ in. long; branches few, short, erect. Spikelets 6–15, 3–5-flowered, $\frac{1}{5}$–$\frac{1}{6}$ in. long, the lower flowers sessile at the base of the spikelet, the upper usually remote from one another. Empty glumes unequal, the lower $\frac{1}{2}$–$\frac{2}{3}$ the length of the upper, glabrous, oblong, obtuse, 3-nerved. Flowering glumes ovate or broadly ovate-oblong, rounded at the back, not keeled, 5-nerved, glabrous or very faintly pubescent on the nerves, minutely 3-toothed at the tip or irregularly erose. Palea broad, 2-keeled, the keels ciliolate. Lodicules 2, acute.

Macquarie Island: Common on the coast, in crevices in the bare rock or on the cliffs, *H. Hamilton!* (Mawson Expedition).

A puzzling plant to place. It differs from *Poa* mainly in the flowering glumes being rounded on the back, and minutely 3-toothed (or irregularly erose) at the tip. It agrees with *Atropis* in the flowering glumes being rounded on the back, but differs in habit and in the 3-toothed tip of the flowering glume. Although it is not a typical *Triodia*, it must be kept in the vicinity of the New Zealand *T. australis*, which is its nearest ally.

27. **KOELERIA** Pers.

Perennial or annual grasses. Leaves narrow; ligules hyaline. Spikelets 2–5-flowered with the uppermost flower sterile, laterally compressed, shining, densely crowded in spike-like panicles; rhachilla disarticulating above the outer glumes and between the flowering glumes, produced beyond the uppermost flower. Two outer glumes persistent, empty, unequal, keeled, acute or acuminate, margins hyaline. Flowering glumes exceeding the outer glumes, with broader hyaline margins, 3–5-nerved, entire or bifid, acuminate or mucronate or shortly awned. Palea white and hyaline, 2-toothed. Lodicules 2. Stamens 3. Styles short, distinct; stigmas plumose. Grain oblong, laterally compressed, free within the flowering glume and palea.

Species 12 or 15, mainly in the temperate parts of the Northern Hemisphere, rarer in the South Temperate Zone. The single New Zealand species is also found in South America.

1. **K. Kurtzii** *Hack. in Bolet. Acad. Sc. de Cordoba*, xvi (1900) 261.—Culms densely tufted, erect, slender, glabrous or pubescent, 6–24 in. high. Leaves crowded near the base of the culms, 2–9 in. long, $\frac{1}{6}$–$\frac{1}{8}$ in. broad, flat, soft or almost flaccid, glabrous or more or less pubescent, sometimes almost villous; sheaths long, rather tight, striate, pubescent or villous; ligules short, truncate, ciliolate. Panicle 1–5 in. long, cylindric, usually dense and spike-like, but sometimes irregularly interrupted or lobed; branches short, erect, minutely villous-pubescent. Spikelets pale-green or pale purplish-green, shining, about $\frac{1}{5}$ in. long, 2–3-flowered. Two outer glumes broadly lanceolate, hyaline, acute, 3-nerved, often scabrid on the keel. Flowering glumes oblong-lanceolate, glabrous or minutely rough on the back, 5-nerved, tip minutely 2-toothed or almost entire, with a very short scabrid awn inserted just below the teeth.—*Cheesem. Man. N.Z. Fl.* (1906) 897. K. cristata *Hook. f. Fl. Nov. Zel.* i (1853) 305; *Handb. N.Z. Fl.* (1864) 334; *Buch. N.Z. Grasses* (1879) t. 38 (*not of Pers.*). K. micrathera *Griseb. in. Goett. Abh.* xxi (1879) 292 (*but not* Trisetum micratherum *Desv.*).

See Domin for new spp. of Koeleria

North Island: Kaimanawa Ranges, *B. C. Aston!* South Island: Abundant in hilly and mountainous localities throughout. Sea-level to 4500 ft.

Also in temperate South America (Argentina), and probably also in Australia. Professor Hackel distinguishes it from the northern *K. cristata* by the flowering glume being minutely 2-toothed at the apex with a short awn protruding from below the sinus, whereas in *K. cristata* the flowering glume is entire and not awned. I find that the awn varies much in length, and is frequently almost obsolete.

Since the first edition of this work was published an elaborate monograph of the genus has been prepared by Dr. Karl Domin. In it the author has increased the number of species admitted in the "Genera Plantarum" (12) and the "Pflanzenfamilien" (15) to no less than 61, and even then he is careful to state that several of these are "collective species," and that the full number is 89. Moreover, many of his "species" are further separated into subspecies, varieties, subvarieties, forms, &c. Domin's account of the variable *K. cristata* covers no less than 65 pages of his monograph. The single New Zealand species, which Professor Hackel has assured me "is quite identical" with the South American *K. Kurtzii*, Dr. Domin not only separates from that plant, but divides it into three species confined to New Zealand. These species are mainly, if not altogether, founded on a collection sent by myself to Professor Hackel, all of which he included, without any hesitation, under *K. Kurtzii*. After a careful re-examination, I can make no other disposition of them than that given above. In case any one should wish to identify them, the following key, which I have adopted from Domin's work, may serve the purpose:—

Awn dorsal.	
Small; culms not creeping at the base	1. *K. novo-zelandica.*
Larger; culms creeping at the base	2. *K. superba.*
Awn strictly terminal	3. *K. Gintlii.*

28. **POA** Linn. 1737

Annual or perennial grasses. Leaves flat or convolute; ligules hyaline. Spikelets usually 2–6-flowered, laterally compressed, in lax or contracted rarely spiciform panicles; rhachilla disarticulating above the two outer glumes and between the flowering glumes, glabrous or sparsely hairy. Two outer glumes persistent, empty, keeled, membranous, 1–2-nerved, usually shorter than the flowering glumes. Flowering glumes obtuse or acute, not awned, keeled, 5–7-nerved or rarely 3-nerved, nerves often conniving near the top, callus and marginal nerves often clothed with crisped or tangled woolly hairs. Palea shorter than the flowering glume, 2-keeled. Lodicules 2. Stamens 3. Ovary glabrous; styles short, distinct; stigmas plumose. Grain ovoid or oblong or linear-oblong, compressed, often grooved, free or adherent to the palea; hilum small, basal, punctiform.

A large genus of over 150 species, comprising several important fodder-grasses, abundant in all temperate and cold climates, in the tropics found only on high mountains. The species are in all countries highly variable and difficult of discrimination, but nowhere more so than in New Zealand. Of the 28 species admitted in this work, 2 extend to Australia and Tasmania, the remainder are endemic. In addition to the indigenous species, several others from the Northern Hemisphere are now well established in most districts, the most abundant being *P. annua* Linn., *P. pratensis* Linn., and *P. trivialis* Linn., descriptions of which will be found in any British Flora. The last-mentioned has become even naturalized near the landing-places on the Auckland Islands and Antipodes Island; and on account of the remoteness of the locality has been described as an indigenous species, under the name of *P. antipoda* (Petrie in Subantarct. Is. N.Z. ii (1909) 478).

A. Two outer glumes reaching more than half-way up the flowering glumes immediately above them. Flowering glumes acuminate, often incurved at the tip. Anthers $\frac{1}{15}$–$\frac{1}{10}$ *in. long, linear.*

* Culms few-noded, densely tufted, erect.

Culms 1–4 ft., leafy throughout. Leaves flat, $\frac{1}{3}$–$\frac{3}{4}$ in. broad. Panicle 3–10 in. Flowering glumes prominently 5-nerved. Callus with base of keel and margins villous with crisped hairs	1. *P. foliosa.*

Culms 5–20 in., leafy throughout. Leaves flat, $\frac{1}{6}$–$\frac{1}{4}$ in. broad. Panicle 2–4 in. Flowering glumes 5-nerved, glabrous except a tuft of crisped hairs on the callus .. 2. *P. Hamiltoni.*

Culms 3–18 in., leafy at the base. Panicle 1–4 in. Flowering glumes faintly nerved, glabrous except a tuft of crisped hairs on the callus .. .. 3. *P. novae-zelandiae.*

Culms tall, 2–3 ft. Leaves linear-filiform. Panicle 3–5 in. Spikelets $\frac{1}{3}$ in., 4–5-flowered .. .. 4. *P. litorosa.*

Culms shorter, 12–15 in. Panicle ovate-oblong, 2–2$\frac{1}{2}$ in. Spikelets $\frac{1}{4}$ in., 5–6-flowered .. .. .. 5. *P. Astoni.*

Culms 12–18 in. Panicle very narrow-linear, 2–4 in. Flowering glumes finely acuminate, callus and keel with floccose hairs .. .. 6. *P. oraria.*

** Culms many-noded, decumbent or prostrate at the base, much branched. Panicle narrow.

Culms prostrate or pendent from cliffs, much branched. Leaves flat, flaccid, $\frac{1}{10}$–$\frac{1}{5}$ in. broad. Panicle 1–2 in. long 7. *P. ramosissima.*

Culms creeping or prostrate at the base. Leaves linear, almost filiform. Panicle 2–4 in. long .. .. 8. *P. Guthrie-Smithiana.*

Culms 6–18 in., branched, distichously leafy. Leaves flat or complicate. Panicle 1–3 in. .. .. .. 9. *P. polyphylla.*

B. Two outer glumes reaching more than half-way up the flowering glumes immediately above them. Flowering glumes obtuse or subacute, rarely acute. Anthers $\frac{1}{20}$–$\frac{1}{10}$ in. long, linear.

* Culms long or short; rhizome tufted or stoloniferous. Leaves flat or complicate or involute, not terete nor polished, not specially rigid, never pungent-pointed.

† Rhizome tufted. Ligules reduced to a truncate rim.

Culms 6–36 in., usually stout. Leaves flat or concave, $\frac{1}{10}$–$\frac{1}{4}$ in. broad. Panicle large; branches usually ternate or quinate. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. Flowering glumes minutely scaberulous, keel scabrid, callus and lower part of glume with a few crisped hairs .. .. 10. *P. anceps.*

Culms 4–15 in., slender. Leaves narrow, sometimes filiform. Panicle 1$\frac{1}{2}$–3 in., branches usually binate. Spikelets $\frac{1}{6}$–$\frac{1}{5}$ in. Flowering glumes as in *P. anceps* but smoother 11. *P. seticulmis.*

†† Rhizome creeping or stoloniferous; ligules short, truncate.

Culms 1–9 in. Leaves narrow, setaceous. Panicle $\frac{1}{2}$–2 in., few-flowered. Spikelets $\frac{1}{8}$–$\frac{1}{6}$ in. Flowering glumes smooth, callus and lower part of keel and margins with crisped hairs .. .. 12. *P. pusilla.*

Culms 4–6 in. Leaves soft and flaccid. Panicle 2–2$\frac{1}{2}$ in. Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. Flowering glumes ovate, glabrous or with few crisped hairs on the callus .. .. .. 13. *P. aucklandica.*

Culms 6–15 in. Leaves usually shorter than the culms, flaccid. Panicle broad, lax, few-flowered. Spikelets $\frac{1}{3}$ in. long, 4–8-flowered .. .. 14. *P. dipsacea.*

Culms 12–18 in. Leaves much shorter than the culms, rigid, erect, obtuse. Panicle broad, spreading. Spikelets $\frac{1}{4}$ in. long, 5–6-flowered .. .. 15. *P. Cheesemanii.*

Culms 12–20 in. Leaves shorter than the culms, rigid, acute. Panicle broad, lax. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. long, 2–3-flowered .. .. 16. *P. Cockayniana.*

††† Rhizome creeping, stoloniferous; ligules a transverse band of short dense hairs.

Culms 12–24 in. Leaves shorter than the culms, rigid, erect. Panicle 1$\frac{1}{2}$–3 in., dense. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. Flowering glumes 4–5-nerved .. .. .. 17. *P. chathamica.*

Poa antipoda Petrie in Trans. Ns. 2: 1909: 478
cf. P. trivialis

** Culms tufted, strict, erect, smooth and polished. Leaves terete or nearly so, erect, rigid, acute or pungent-pointed.

† Ligules almost obsolete.

Culms 1–3 ft., forming dense tussocks. Flowering glumes prominently 5-nerved; callus and base of keel with a tuft of long crisped hairs .. .. 18. *P. caespitosa.*

†† Ligules long, hyaline, sheathing (except in var. *breviligulata* of *P. Colensoi*).

Culms 2–15 in., longer than the leaves. Panicle $\frac{1}{2}$–3 in. Flowering glumes faintly 5-nerved, smooth or nearly so, callus with a tuft of crisped hairs .. .. .. 19. *P. Colensoi.*

Culms 2–6 in. Leaves imbricated, very short and rigid, with acicular points. Panicle $\frac{1}{2}$–1 in., few-flowered. Flowering glumes villous with short silky hairs below the middle, minutely rough above .. .. .. 20. *P. acicularifolia.*

*** Culms $\frac{1}{2}$–1 in., densely tufted and compacted, forming patches 2–6 in. across. Leaves $\frac{1}{6}$–$\frac{1}{2}$ in. long. Panicle reduced to 1–2 spikelets.. 21. *P. pygmaea.*

C. Two outer glumes reaching more than half-way up the flowering glumes immediately above them. Flowering glumes broad, obtuse. Anthers small, often minute, $\frac{1}{25}$–$\frac{1}{15}$ in. long, oblong.

Culms 6–18 in., stout or slender, leafy throughout. Panicle 2–6 in., many-flowered. Spikelets $\frac{1}{6}$–$\frac{1}{3}$ in., green or purplish-green. Flowering glumes prominently 5-nerved, glabrous or rarely with a tuft of hairs on the callus .. 22. *P. Kirkii.*

Culms 3–12 in., slender and delicate, leafy at the base. Panicle 1–3 in., few-flowered. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in. long, silvery-brown. Flowering glumes faintly 5-nerved, silky with short white hairs .. .. 23. *P. Lindsayi.*

Culms 2–4 in., leafy throughout. Panicle lax, few-flowered. Spikelets 3–6, turgid, $\frac{1}{8}$–$\frac{1}{6}$ in. long, purplish-brown. Flowering glumes glabrous .. .. 24. *P. incrassata.*

Culms 1–5 in., leafy throughout. Panicle contracted, few-flowered. Spikelets compressed, $\frac{1}{10}$–$\frac{1}{8}$ in., green tinged with purplish-red. Flowering glumes quite glabrous, margins white and membranous .. .. .. 25. *P. exigua.*

Culms 1–3 in., leafy at the base. Panicle contracted into an oblong head $\frac{1}{4}$–$\frac{1}{3}$ in. long. Spikelets 4–12, $\frac{1}{6}$ in. long, pale glaucous-green. Flowering glumes silky with short crisped hairs .. .. 26. *P. maniototo.*

Culms 2–8 in., rigid. Leaves rough with minute asperities. Panicle $\frac{3}{4}$–2 in. long, dense and spiciform, many-flowered. Spikelets $\frac{1}{8}$ in. Flowering glumes quite glabrous, margins white and membranous .. .. .. 27. *P. sclerophylla.*

D. Two outer glumes not reaching half-way up the flowering glumes immediately above them. Flowering glumes broadly oblong or ovate-oblong, obtuse or acute. Anthers minute, $\frac{1}{50}$ in.

Culms 4–15 in., slender, leafy, flaccid. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in. Outer glumes minute, often unequal .. .. .. 28. *P. imbecilla.*

1. **P. foliosa** *Hook. f. Handb. N.Z. Fl.* (1864) 338 (*excl. var.* b).—Often forming large tussocks. Culms densely tufted, 1–4 ft. high, $\frac{1}{3}$–$\frac{2}{3}$ in. diam. at the base, stout, erect, leafy, compressed below. Leaves very numerous, subdistichous, usually exceeding the culms, 1–4 ft. long, $\frac{1}{3}$–$\frac{3}{4}$ in. broad, gradually narrowed into acuminate points, flat, coriaceous, glabrous, minutely scabrid above, somewhat glaucous beneath; sheaths rather lax, broad, compressed, striate, glabrous; ligules short, membranous, entire or dentate. Panicle large, linear-oblong, dense, contracted, inclined or nodding, 3–10 in. long, 1–3 in. broad; rhachis stout, grooved, glabrous;

branches suberect, much divided, slender, glabrous, multi-spiculate. Spikelets shortly pedicelled, much compressed, rather large, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 3–5-flowered. Two outer glumes slightly unequal, keeled, acuminate; the lower subulate-lanceolate, 1-nerved; the upper broader and larger, about $\frac{2}{3}$ the length of the whole spikelet, lanceolate, 3-nerved. Flowering glumes ovate-lanceolate, acuminate, incurved at the tip, prominently 5-nerved; callus, together with the back and margins for $\frac{1}{2}$ their length, clothed with crisped silky hairs; upper portion of the glume scabrid. Palea $\frac{1}{3}$ shorter than the glume, linear-oblong, bifid at the tip.—*Buch. N.Z. Grassses* (1880) t. 42; *Cheesem. Man. N.Z. Fl.* (1906) 900. Festuca foliosa *Hook. f. Fl. Antarct.* i (1844) 99, t. 55.

STEWART ISLAND: Herekopere Island and headlands near the South Cape, *T. Kirk!* Codfish Island, Breakfast Island, and Long Island, *Poppelwell!* THE SNARES AND SOLANDERS: *T. Kirk! Chapman! Cockayne!* AUCKLAND AND CAMPBELL ISLANDS: *Hooker, Buchanan! T. Kirk! F. R. Chapman! B. C. Aston!* ANTIPODES ISLAND: *T. Kirk!* MACQUARIE ISLAND: *Fraser, Professor Scott, A. Hamilton! H. Hamilton!*

(Petrie) Trans. 73:236.

Var. **Tennantiana** *Cheesem.*—Smaller in all its parts. Culms densely tufted, 1–2 ft. high, $\frac{1}{3}$–$\frac{1}{2}$ in. diam. at the base. Panicle smaller, 3–6 in. long. Spikelets $\frac{1}{5}$ in. long, 2–4-flowered.—P. Tennantiana *Petrie in Subantarct. Is. N.Z.* ii (1909) 476. Barely differs from *P. foliosa* except in the reduced size and fewer-flowered spikelets.

Easily distinguished from all other New Zealand species by the great size, very broad flat leaves, and large dense panicle. It is closely allied to the Kerguelen Island *P. Cookii* Hook. f., and to the well-known tussock-grass of the Falkland Islands and Fuegia, *P. flabellata* Hook. f. (*Dactylis caespitosa* Forst.). The flowers seem to be partly if not altogether unisexual, most of the specimens that I have seen being females with the anthers much reduced in size.

2. **P. Hamiltoni** *T. Kirk in Trans. N.Z. Inst.* xxvii (1894) 353.—Perennial, densely tufted, 5–20 in. high. Culms shorter than the leaves, erect, stout, sometimes $\frac{1}{3}$ in. diam. below, compressed, leafy almost up to the base of the panicle. Leaves numerous, subdistichous, lower much reduced in size and sheathing the culm, gradually passing into the upper, which usually far overtop the paniele, $\frac{1}{6}$–$\frac{1}{4}$ in. diam. at the base, from thence gradually tapering into a long acuminate point, flat, coriaceous, many-striate, smooth and glabrous, not scabrid; ligules large, broad, ovate, membranous, deeply and irregularly laciniate; sheaths long, compressed, thin and rather membranous, regularly striate. Panicle linear-oblong or linear-obovate; sometimes almost clavate, dense and contracted, rarely sublobed towards the base, 2–3$\frac{1}{2}$ in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad, usually strict and erect; branches close-set, rarely more than 1$\frac{1}{2}$ in. long. Spikelets rather large, compressed, $\frac{2}{3}$–$\frac{3}{5}$ in. long, 2–4-flowered; lower flower almost sessile, upper pedicelled. Outer glumes unequal, but not remarkably so, ovate-lanceolate, acuminate, 3-nerved; flowering glumes lanceolate or ovate-lanceolate, acuminate or almost awned, incurved at the tip, keeled, 5-nerved, scabrid on the keel and nerves, shortly hairy on the sides towards the base, but not webbed with cottony hairs. Palea linear-oblong, bifid at the tip, ciliate on the margins and keel, about $\frac{1}{3}$ shorter than the glume. Lodicules broad-ovate, acute. Anthers large, narrow-linear, about $\frac{1}{10}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 1156; *Petrie in Subantarct. Is. N.Z.* ii (1909) 477; *Cheesem. in Vascl. Flora Macquarie Is.* (1919) 36.

MACQUARIE ISLAND: On rocks near the sea, usually fringing the *Poa foliosa* belt, *A. Hamilton, H. Hamilton!*

One of the few endemic plants of the island, and a very distinct species. It is best characterized by the short strict culms, the deeply laciniate ligule, and the short and narrow much contracted panicle. Kirk states that its nearest allies are *P. foliosa* and *P. anceps*. It doubtless belongs to the *P. foliosa* group; but it has little affinity with *P. anceps*, from which it differs in the mode of growth, in the leaves, and particularly in the deeply laciniate ligule, which is widely different from the truncate rim-like ligule of *P. anceps*, also in the acuminate and inourved flowering glumes and the large anthers. The particulars given above have been mainly drawn from my "Vascular Flora of Macquarie Island" (Australian Antarctic Expedition, vol. vii, part 3).

3. **P. novae-zealandiae** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 381.—Perennial, tufted, innovation-shoots intravaginal or mixed. Culms erect, 3–18 in. high, slender, glabrous, 3-noded, upper node about the middle of the culm. Leaves usually much shorter than the culms, 2–10 in. long, $\frac{1}{12}$–$\frac{1}{4}$ in. broad, linear, suddenly acuminate at the tip, flat or those of the innovation-shoots complicate, erect, quite glabrous, finely striate; sheaths lax, compressed; ligules ovate, acuminate, often dentate. Panicle broadly ovate to ovate-oblong or linear-oblong, dense, nodding or more rarely erect, 1–4 in. long; rhachis smooth, terete; branches binate or ternate, once or twice divided, smooth, capillary. Spikelets pale-green or whitish-green, much compressed, elliptic-oblong, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 5–6-flowered. Two outer glumes slightly unequal, acuminate, glabrous; lower subulate-lanceolate, 1-nerved; upper longer and broader, about $\frac{1}{2}$ as long as the whole spikelet or rather more, lanceolate, 3-nerved. Flowering glumes lanceolate, acuminate, often incurved at the tip, usually 5-nerved, but the intermediate nerve on each side faint and sometimes obsolete, callus with a tuft of crisped woolly hairs more than $\frac{1}{2}$ as long as the glume, remainder of the glume glabrous, smooth. Palea $\frac{1}{3}$ shorter than the glume, linear-oblong, bidentate, pubescent on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 901. P. foliosa *var.* b *Hook. f. Handb. N.Z. Fl.* (1864) 338; *Buch. N.Z. Grasses* (1880) t. 43. Festuca foliosa *Hook. f. Fl. Nov. Zel.* i (1853) 308 (*not of Fl. Antarct.*).

Var. **subvestita** *Hack. l.c.*—Flowering glumes rather longer, clothed with crisp hairs in the lower $\frac{1}{3}$, exterior lateral nerves more prominent. Spikelets often tinged with violet.

Var. **Wallii** *Petrie MS.*—Stout, depauperated, 2–4 in. high. Panicle short, broad, dense, sunk among the leaves. — Mount Miromiro, Amuri, *A. Wall!* Raglan Mountains, Wairau Valley, 5000 ft., *T. F. C.* Distinguished by Hackel as "*forma humilior.*"

North Island: Mount Hikurangi, *Petrie!* Tongariro, Ngauruhoe, and Ruapehu, *T. F. C., Cockayne!* Mount Egmont, *Buchanan! T. F. C.;* Tararua Mountains, *Buchanan! W. Townson!* South Island, Stewart Island: Abundant in damp alpine and subalpine localities. 2500–6500 ft.

Separated without any difficulty from *P. foliosa*, with which it was placed by Hooker, by the different habit, much smaller size, shorter narrower and smoother leaves, smaller and proportionately broader panicle, and less prominently nerved flowering glumes, which are less silky at the base, and almost smooth above.

4. **P. litorosa** *Cheesem. Man. N.Z. Fl.* (1906) 1156.—A tall densely tufted species, often forming tussocks 2–4 ft. high. Culms many, branched at the base, and there closely compacted together, leafy, quite glabrous, 2–3-noded, striate. Leaves much longer than the culms, narrow linear-filiform, gradually drawn out into long acuminate points, strongly involute throughout, coriaceous, glabrous, striate, erect at the base, curving

outwards above; sheaths very long, smooth, shining; ligules oblong, membranous. Panicle 3–5 in. long, erect or inclined, closely branched or more or less open; branchlets few or many, finely scaberulous. Spikelets pedicelled, compressed, ovate-oblong to ovate-lanceolate, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 4–6-flowered. Empty glumes slightly unequal, barely $\frac{1}{2}$ the length of the spikelet, lanceolate, acute, 3-nerved, the central nerve alone excurrent. Flowering glumes ovate-lanceolate, acute or subacute, prominently 5-nerved, callus, margins, and lower part of the keel with long crisped hairs, becoming shorter towards the middle of the glume, the upper part of the glume minutely scaberulous. Palea $\frac{1}{4}$ shorter than the glume, linear-oblong, bidentate, scabrid on the keels.—Poa Poppelwellii *Petrie in Trans. N.Z. Inst.* xlvi (1914) 38. Festuca scoparia *Hook. f. Fl. Antarct.* i (1844) 98 (*not* Poa scoparia *Kunth.*). Trans 45 : 264

Auckland and Campbell Islands: *Hooker, T. Kirk, Cockayne! B. C. Aston!* and others. Herekopere Island: *H. Guthrie-Smith!*

This, with *Poa foliosa* and *Danthonia antarctica*, constitute the chief "tussock-grasses" of the Subantarctic islands. I am unable to separate from it Mr. Petrie's *P. Poppelwellii*, based on cultivated specimens originally from Herekopere Island.

5. **P. Astoni** *Petrie in Trans. N.Z. Inst.* xxxviii (1906) 423.—Culms densely tufted, 12–15 in. high. Leaves equalling or exceeding the culms, very narrow, linear-filiform, gradually narrowed into an almost pungent point, closely involute, striate, glabrous; sheaths long, compressed, striate; ligules broadly triangular, acute. Panicle 2–2½ in. long, ovate or ovate-oblong, rather dense; branches short, simple or divided. Spikelets compressed, ovate-oblong, $\frac{1}{4}$ in. long, 5–6-flowered. Two outer glumes about $\frac{1}{2}$ as long as the spikelet, subequal, broadly lanceolate, acuminate, glabrous, 3-nerved. Flowering glumes ovate-lanceolate, acuminate, keeled, strongly 5-nerved, usually with a tuft of crisped hairs on the callus and lower part of the keel, but frequently without. Palea linear-oblong, bidentate, ciliate-scabrid on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 1165. Festuca scoparia *Hook. f. Handb. N.Z. Fl.* (1864) 341 (*in part, but not of Fl. Antarct.* i, 98); *Buch. N.Z. Grasses* (1880) t. 55A.

South Island: Coastal Cliffs at Okarito, *Cockayne.* Rocky cliffs on the coast-line of Otago, not uncommon. Stewart Island (and small islands in the vicinity): Common along the coast. The Solanders and Snares: *Cockayne.* Auckland Island: *B. C. Aston.*

This is closely allied to *P. litorosa*, from which it is best distinguished by its smaller size and more slender habit, and the usually smaller spikelets. Many specimens are quite intermediate in their characters.

6. **P. oraria** *Petrie in Trans. N.Z. Inst.* xlii (1910) 196.—Culms numerous, tufted, sparingly leafy, slender, strict, erect, smooth and polished, pale yellowish-green, 12–18 in. high, perfectly glabrous, 2- or rarely 3-noded, the lowest node distant from the base. Leaves longer or shorter than the culms, erect, filiform, strongly involute so that the leaf is almost terete, somewhat rigid and almost pungent-pointed, perfectly smooth and glabrous, striate; sheaths long, broad, membranous; ligule rather long, oblong, obtuse. Panicle 2–4 in. long, very narrow, linear, strict, erect; branches few, suberect, short, simple or sparingly divided; pedicels slender. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. long, 4–5-flowered. Two outer glumes subequal, about $\frac{1}{3}$ shorter than the spikelet, linear-lanceolate, acuminate, 3-nerved. Flowering glumes narrow-lanceolate, finely acuminate, membranous, 5-nerved, callus and lower part of keel sparingly pilose with floccose hairs, the keel and nerves

6. placed by Cotton as var. γ P. astoni Trans 73 : 236.

Poa wallii Petrie Trans 54:1923:571 Top of Craigieburn Ra. A.W.

above more or less scabrid with stiff silky hairs. Palea shorter than the flowering glumes, 2-nerved, the nerves slightly scaberulous.

South Island: Wet places at the head of Deep Cove, and others of the West Coast Sounds of Otago, *B. C. Aston!*

7. **P. ramosissima** *Hook. f. Fl. Antarct.* i (1844) 101.—Culms very numerous, densely packed, forming large prostrate masses on steep banks, or pendent from moist cliffs, 12–18 in. long, naked at the base or clothed with the remains of the old leaves, many-noded, much and fasciculately branched above. Branches many times divided, slender, leafy, flaccid, 2–9 in. long. Leaves much longer than the culms, 3–6 in. long, $\frac{1}{12}$–$\frac{1}{5}$ in. broad, narrow linear-subulate, acute, flat, flaccid, quite smooth and glabrous, obsoletely striate; sheaths long, slender, smooth, striate, fissured to the base; ligules oblong, membranous, lacerate. Panicle dense and contracted, linear-oblong, erect, 1–2 in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad; rhachis slender, smooth; branches short, erect, $\frac{1}{4}$ in. long, quite smooth and glabrous, bearing 3–4 shortly pedicelled spikelets. Spikelets $\frac{1}{5}$–$\frac{1}{4}$ in. long, ovate-lanceolate, acute, compressed, 3–5-flowered. Two empty glumes subequal, rather more than $\frac{1}{2}$ as long as the spikelet, lanceolate, acuminate, often incurved at the tips, glabrous; the lower 1-nerved, the upper broader, 3-nerved. Flowering glumes ovate-lanceolate, acuminate, keeled, 5-nerved, but the lateral nerves obscure, smooth and glabrous, callus at the base glabrous or with a tuft of crisped hairs. Palea linear-oblong, shorter than the flowering glume. Anthers long, linear.—*Hook. f. Handb. N.Z. Fl.* (1864) 338; *Cheesem. Man. N.Z. Fl.* (1906) 902; *Cockayne Veg. N.Z.* (1921) t. 88.

Auckland and Campbell Islands: Abundant near the sea, *Hooker! Cockayne! B. C. Aston!* and others.

Sir J. D. Hooker remarks that "this is a very abundant grass in both groups of islands, and of a most singular habit of growth. The culms are invariably prostrate and quite simple for a foot or two, when they suddenly ascend and divide into many short branches, each bearing a panicle of flowers. It forms a copious soft green herbage, especially on the banks near the sea, always throwing its long culms over the edges of the cliffs, which are thus fringed with a delicate festoon of green."

8. **P. Guthrie-Smithiana** *Petrie in Trans. N.Z. Inst.* xlv (1913) 275.—Culms densely tufted, creeping or prostrate at the base, many-noded, emitting from the nodes numerous intravaginal excessively slender erect or ascending branches 5–10 in. long. Leaves shorter than the culms, very narrow-linear, almost filiform, complicate, firm, erect, smooth and glabrous, obscurely striate, acute; sheaths long, much broader than the blade, fissured to the base, thin, striate; ligule thin, membranous, acute. Panicle 2–4 in. long, narrow-linear, dense, strict and erect; branches short, erect, in whorls of 3–5, minutely scaberulous. Spikelets shortly pedicelled, $\frac{1}{5}$–$\frac{1}{4}$ in. long, 3–5-flowered. Two outer glumes unequal, barely $\frac{1}{3}$ the length of the spikelet, lanceolate, acute, glabrous; lower 1-nerved, upper faintly 3-nerved. Flowering glumes oblong-lanceolate, acute or subacute, keeled, smooth and glabrous, 3-nerved, the central nerve often excurrent, margins thin and scarious, callus and base of keel with a few long crisped hairs. Palea nearly as long as the glume, linear-oblong, ciliate on the keels. Zotov. Trans 73:236 places this as P. colensoi var. Guthrie-Smithiana

Herekopere Island (off Stewart Island): *H. Guthrie-Smith!*

The above description has been drawn up from cultivated specimens grown in Mr. Petrie's garden, and may need revision when wild specimens are available. The species is remarkable for its slender habit, filiform leaves, and extremely narrow panicle.

Poa affinis R.Br. Pr. N.Z. i 207 } not taken up by Cheesem.
= uniflora Buch. t. xlix B. }

9. **P. polyphylla** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 383.—Tufted; innovation-shoots extravaginal. Culms erect or decumbent at the base and then ascending, often much branched, many-noded, compressed, glabrous, wiry, 6–18 in. high. Leaves numerous, sheathing the culm, distichously spreading, 4–10 in. long, about $\frac{1}{10}$ in. broad, flat or complicate, lower portion smooth, upper part scabrid on the margins and keel; sheaths overlapping, tight, compressed, grooved; ligules reduced to a narrow truncate rim. Panicle 1–3 in. long by $\frac{1}{2}$–1 in. broad, oblong, dense, contracted; branches usually binate, short, erect, divided, spiculate almost to the base, more or less scabrid. Spikelets oblong, compressed, 4–5-flowered, $\frac{1}{5}$–$\frac{1}{4}$ in. long. Two outer glumes unequal, lanceolate, acuminate, 1-nerved, sharply scabrid along the keel, the upper the longer, rather more than $\frac{1}{2}$ the length of the spikelet. Flowering glumes lanceolate, sharply acuminate, almost mucronate, keeled, prominently 5-nerved, minutely scabrid on the surface and nerves and sharply scabrid along the keel, callus and lower part of keel with long crisped woolly hairs. Palea slightly shorter than the glume, linear-oblong, scabrid on the keels. Anthers long.—*Cheesem. Man. N.Z. Fl.* (1906) 903; *Ill. N.Z. Fl.* ii (1914) t. 229. Placed by Zotov (13: 236) a var. of anceps.

Kermadec Islands: Abundant on Sunday and Macaulay Islands, chiefly near the sea, *T. F. C., Miss Shakespear! W. R. B. Oliver!*

Distinguished by the branching habit, distichously spreading leaves, short contracted panicle, and narrow acuminate flowering glumes, which are sharply scabrid on the keel, and scaberulous on the surfaces and veins.

10. **P. anceps** *Forst. f. Prodr.* (1786) n. 43.—Perennial, very variable; innovation-shoots extravaginal. Culms tufted, often branched at the base, stout, compressed, glabrous, leafy, 10–36 in. high or even more. Leaves longer or shorter than the culms, subdistichous, 9–18 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, acute or acuminate, rather coriaceous, flat or concave, smooth on both surfaces or the margins slightly scabrid near the apex; sheaths compressed, grooved; ligules a short truncate rim. Panicle very variable, 4–12 in. long, 1–5 in. broad, lanceolate to oblong or ovate, effuse or contracted, rather dense or open, inclined or erect; rhachis smooth or scaberulous; branches short or long, suberect or spreading, 2 or 3 or more from one node, once or twice divided; branchlets capillary, scaberulous. Spikelets ovate-oblong, compressed, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 4–6-flowered. Two outer glumes unequal, not $\frac{1}{2}$ the length of the spikelet, but reaching $\frac{3}{4}$-way up the flowering glume above them, lanceolate, acuminate, 3-nerved, scabrid on the keel and sides or almost glabrous. Flowering glumes oblong to oblong-ovate, obtuse or subacute, keeled, prominently 5-nerved, minutely scaberulous on the surface and nerves or almost smooth, keel usually scabrid, callus and lower part of keel with a few crisped hairs or almost glabrous. Palea almost as long as the flowering glume, linear-oblong, minutely ciliate-scabrid on the keels. Anthers long.—*Hook. f. Fl. Nov. Zel.* i (1853) 306; *Handb. N.Z. Fl.* (1864) 339; *Buch. N.Z. Grasses* (1880) t. 44; *Cheesem. Man. N.Z. Fl.* (1906) 904. P. australis *A. Rich. Fl. Nouv. Zel.* (1832) 141; *A. Cunn. Precur.* (1836) n. 262; *Raoul Choix* (1846) 39 (*not of R. Br.*).

1906

Var. **condensata** *Cheesem.*—Culms 4–18 in. high, often overtopped by the leaves. Panicle shorter and much more compact, dense-flowered. Spikelets rather smaller, 2–4-flowered. Glumes smoother, hardly scaberulous.

Var. **gracilis** *Cheesem.*—Culms slender, 4–18 in. high. Leaves narrow, often involute. Panicle lax; branches few, 2–3 from each node or solitary; spikelets fewer, towards the tips of the branchlets, smaller, 2–5-flowered. Glumes smoother. This appears to connect the type with *P. seticulmis.*

North and South Islands: The typical form throughout the whole of the North Island, ranging from sea-level to 3500 ft., apparently rare and local in the South Island, but recorded from Marlborough and Nelson, and extending along the West Coast to the south of Westport. Var. *condensata* not uncommon as far as Canterbury, but apparently rare to the south of Marlborough; var. *gracilis* has somewhat the same range.

What I consider to be the typical state of this variable plant includes the two varities *elata* and *foliosa* of the Handbook, and can be distinguished by the tall stout culms often branching at the base, broad and flat subdistichous smooth leaves, large usually lax panicle, and numerous rather large spikelets, with subacute flowering glumes prominently nerved and usually more or less finely scaberulous. But it runs on all sides into numerous varieties exceedingly difficult to define, if, indeed, they are capable of exact circumscription.

11. **P. seticulmis** *Petrie in Trans. N.Z. Inst.* xxxiv (1902) 391.—Culms tufted, branched at the base, very slender, erect, smooth and glabrous, 4–12 in. high. Leaves shorter or longer than the culms, very narrow, usually involute and filiform, rarely slightly broader and flat, erect, smooth, striate; sheaths pale, membranous, grooved; ligules reduced to a narrow membranous ciliolate rim. Panicle 1½–3 in. long, ovate to oblong, lax, few-flowered; rhachis capillary, scaberulous above; branches few, in distant pairs or the upper solitary, spreading or suberect, sparingly branched, capillary, scaberulous. Spikelets few at the tips of the branchlets, oblong, ⅙–⅕ in. long, 3–5-flowered. Two outer glumes slightly unequal, about ½ the length of the spikelet or less, lanceolate, acute, 3-nerved, smooth or nearly so. Flowering glumes oblong-ovate, obtuse or subacute, 5-nerved, smooth or minutely scaberulous on the keel, a few crisped hairs on the callus and lower part of the back. Palea almost as long as the glume, ciliate on the keels. Anthers long, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 904.

North and South Islands, Stewart Island: Not uncommon in dry places throughout. Sea-level to 2500 ft.

What may be taken as the typical form of this species is abundant on sandy soil near the sea in the northern part of the North Island, and from its very slender filiform culms and leaves and lax few-flowered panicle presents a very distinct appearance. But, as Mr. Petrie remarks, there is a widely spread inland state that cannot be separated from it by any characters of importance, but which gradually varies into small and slender states of *P. anceps*, the var. *gracilis* of that plant forming a direct connection between the two species.

12. **P. pusilla** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 31, t. 7, f. 35–40.—Rhizome long, creeping and rooting. Culms variable in size, often much dwarfed, 1–9 in. high, erect or ascending, slender, smooth and glabrous, striate. Leaves much shorter than the culms, subdistichous, narrow, involute, setaceous; sheaths pale, compressed, grooved; ligules extremely short, reduced to a mere rim. Panicle variable in size, ½–2 in. long, broadly ovate, lax, few-flowered; branches few, slender, capillary, spreading, in depauperated states reduced to 2 or 3, each with a single spikelet, in large forms 4–8, with 1–4 spikelets at the tip. Spikelets pale-green, ovate, compressed, ⅛–⅙ in. long, 2–5-flowered. Two outer glumes subequal, about ½ as long as the spikelet, oblong-ovate to oblong-lanceolate, acute, 3-nerved, smooth or scabrid on the keel above. Flowering

glumes oblong-ovate, obtuse, 5-nerved, smooth or rarely minutely scaberulous on the keel, callus and lower part of keel and margins with long crisped woolly hairs. Palea about $\frac{3}{4}$ the length of the glume, silky on the keels. Anthers long, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 905. P. anceps *var.* minima *Buch. N.Z. Grasses* (1880) t. 46F.

South Island: Wet places in mountain districts, from the Wairau Valley, Nelson, to the south of Otago. Stewart Island: *T. Kirk! Cockayne.* Sea-level to 5000 ft.

I am greatly puzzled with this species. Forms very closely resembling Berggren's plate and description are not uncommon in subalpine localities in the South Island, but they appear to pass insensibly into a larger lowland state, with a more developed panicle and larger spikelets. This in its turn approaches so near to *P. seticulmis* that it is difficult to draw a strict line of demarcation between the two plants.

13. **P. Aucklandica** *Petrie in Subantarct. Is. N.Z.* ii (1909) 478.—Culms slender, tufted, branched from the base, 4–6 in. high. Leaves equalling the culms, soft and flaccid, narrow-linear, setaceous above, acute; sheaths long, much broader than the blades, fissured to the base, strongly grooved, quite glabrous; ligules oblong, membranous, lacerate. Panicle short, 2–2½ in. long, broadly ovate, lax, few-flowered; branches few, very slender, scaberulous. Spikelets long-pedicelled, large for the size of the plant, $\frac{1}{5}$–$\frac{1}{4}$ in. long, broadly ovate, compressed, 4–5-flowered. Two outer glumes nearly equal, about $\frac{1}{2}$ the length of the spikelet, ovate-lanceolate, acute, 3-nerved. Flowering glumes ovate, acute, 5-nerved, the central nerve often slightly excurrent, glabrous, or with a few crisped hairs on the callus. Palea shorter than the flowering glume, linear-oblong; keels ciliate.

Auckland Islands: Hills above Carnley Harbour, *B. C. Aston!* Campbell Island: *R. M. Laing.*

The only specimens I have seen are few and imperfect and quite insufficient for a proper understanding of the species. Its nearest ally appears to be *P. dipsacea.*

14. **P. dipsacea** *Petrie in Trans. N.Z. Inst.* xxvi (1894) 271.—Culms erect from an often long and branched creeping and rooting base, stout or slender, smooth, leafy, 6–18 in. high. Leaves usually shorter than the culms, narrow, involute or complicate, quite smooth and glabrous, deeply striate; sheaths rather loose, pale, deeply grooved; ligules short, broad, submembranous. Panicle 2–5 in. long, broadly ovate, lax, few-flowered; rhachis smooth; branches usually in distant pairs, simple or forked, smooth, capillary, bearing few large spikelets towards the tips. Spikelets long-pedicelled, elliptic-ovate, compressed, greenish-brown, about $\frac{1}{3}$ in. long, 4–8-flowered. Two outer glumes unequal, almost as long as the flowering glumes immediately above them, lanceolate, acute, membranous, smooth or finely scabrid on the upper part of the keel. Flowering glumes ovate, obtuse or subacute, rather membranous, prominently 5-nerved, callus and lower part of the keel and margins with long silky hairs, upper part of keel sharply scabrid, surface and nerves in the upper half minutely scaberulous. Palea shorter than the glume, keels ciliate. Anthers long, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 906; *Ill. N.Z. Fl.* ii (1914) t. 230.

South Island: Nelson—Raglan Range, *T. F. C.* Canterbury—Wet places near the sources of the Broken River, *Petrie! T. F. C.*; Craigieburn Mountains, *Cockayne!* Mount Peel, *H. H. Allan!* 3000–5000 ft.

This seems to be a distinct species, recognized without much difficulty by the long decumbent bases of the culms, very lax few-flowered panicle, and large spikelets clustered at the tips of the branchlets. Depauperated states approach *P. pusilla,* but are easily distinguished by the larger spikelets and more distinctly nerved scaberulous flowering glumes.

15. **P. Cheesemanii** *Hack. in Trans. N.Z. Inst.* xxxv (1903) 383.—Perennial, hardly tufted; rhizome with creeping stolons furnished with leafless scales. Culms erect or decumbent at the base, slender, smooth, terete, 3-noded, the upper node about half-way up the culm, 12–18 in. high. Leaves much shorter than the culms, 2–6 in. long, about $\frac{1}{12}$ in. broad, rigid, erect, obtuse at the tip, more or less complicate when dry; sheaths shorter than the internodes, subcompressed, keeled in the upper part, glabrous; ligules short, truncate. Panicle ovate, lax, spreading, 2–5 in. long; rhachis smooth, more or less flexuose above; lower branches ternate, upper binate or solitary, slender, almost capillary, lower $\frac{2}{3}$ undivided and smooth, towards the tip bearing a few unispiculate branchlets. Spikelets elliptic, often tinged with red, rather more than $\frac{1}{4}$ in. long, 5–6-flowered. Two outer glumes unequal, $\frac{3}{4}$ the length of the flowering glumes above them or even more, oblong-lanceolate, acute, 3-nerved, quite smooth. Flowering glumes oblong-ovate, subacute, prominently 5-nerved, callus clothed with long crisped woolly hairs $\frac{1}{2}$ the length of the glume, keel and nerves near the base sparingly villous, remainder of the glume smooth and glabrous. Palea almost as long as the glume, linear-oblong, scabrid on the keels. Anthers linear, about $\frac{1}{12}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 906; *Ill. N.Z. Fl.* ii (1914) t. 231.

South Island: Nelson—Lake Tennyson, *T. F. C.*; near Westport, *W. Townson!*

Professor Hackel remarks of this species that it is allied to *P. anceps*, but differs markedly in the stoloniferous rhizome, the rhizome of *P. anceps* being invariably tufted and without stolons. The spikelets are also broader, the two outer glumes longer in proportion and smoother, and the flowering glumes much more hairy at the base and smoother above. *P. dipsacea* differs in the more flaccid habit, larger spikelets, and in the flowering glumes being scabrous above.

16. **P. Cockayniana** *Petrie in Trans. N.Z. Inst.* xlv (1913) 274.—Tufted, much branched at the base, and there clothed with leafless scales. Culms numerous, 12–20 in. high, erect, slender, smooth and glabrous, terete, 2–3-noded, the upper node rather more than half-way up the culm. Leaves shorter than the culms, about $\frac{1}{12}$ in. broad, rigid, erect, more or less complicate when dry, rarely flat, acute at the tip, smooth and glabrous when adult, finely pubescent when young, striate on both surfaces; sheaths long, membranous, grooved or striate; ligules short, broad, erose. Panicle ovate, lax, spreading, 4–6 in. long; rhachis slender, scaberulous; branches long, capillary, the lower 2-nate or rarely 3-nate, upper solitary. Spikelets few, distant, $\frac{1}{4}$–$\frac{1}{3}$ in. long, compressed, ovate, acute, 2–3-flowered. Two empty glumes slightly unequal, $\frac{4}{5}$ the length of the spikelet, oblong-lanceolate, acute, 3-nerved, quite smooth on the face, scabrid on the keel. Flowering glumes oblong, obtuse, membranous, erose at the tip, 5-nerved, margins thin and scarious, callus and lower part of the keel with long cobwebby hairs. Palea shorter than the glume, ciliate on the keels.

South Island: Banks of the Rolleston River, Westland, *Cockayne!* 3000–4000 ft.

Mr. Petrie considers this to be a near ally of *P. dipsacea*, but it is much more closely related to *P. Cheesemanii*, of which it has the habit and foliage, differing chiefly in the more open panicle, and fewer-flowered spikelets.

17. **P. Chathamica** *Petrie in Trans. N.Z. Inst.* xxxiv (1902) 394.—Rhizome long, wiry, creeping and rooting among *Sphagnum*, &c. Culms 1–2 ft. high, often decumbent and branched at the base, erect above,

rather rigid, smooth, leafy. Leaves usually shorter than the culms, narrow, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, erect, rather coriaceous, tapering to a stiff acute point, flat or concave, smooth, striate ; sheaths compressed, lax, grooved ; ligules a transverse band of short stiff white hairs. Panicle 1½–3 in. long, linear-oblong to ovate-oblong, rather dense ; branches few, usually binate, short, slender, capillary, scabrid-ciliate. Spikelets ovate or oblong-ovate, compressed, pale-green or purplish, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 4–5-flowered. Two outer glumes slightly unequal, about $\frac{1}{2}$ the length of the spikelet, oblong-lanceolate, acute, 3-nerved, scabrid on the keel. Flowering-glumes oblong-ovate, obtuse or subacute, prominently 5-nerved, minutely scaberulous on the surfaces and nerves, keel usually strongly scabrid, callus and lower part of keel and margins with sparse crisped woolly hairs. Palea about as long as the glume, bidentate, strongly ciliate on the keels. Anthers long, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 907.

CHATHAM ISLANDS : Abundant in *Sphagnum* swamps, *F. A. D. Cox! Cockayne!*

Closely allied to *P. anceps*, but sufficiently distinct in the creeping rhizome, more coriaceous erect leaves, ligule composed of short stiff hairs, and short dense panicle with few branches and rather large spikelets.

18. **P. caespitosa** *Forst. f. Prodr.* (1786) n. 498.—Culms densely tufted, forming compact tussocks, pale yellowish-green, slender, erect, smooth and polished, 1–3 ft. high. Leaves longer or shorter than the culms, very narrow, often filiform, usually with the margins strongly involute so that the leaf is nearly terete, rarely flat, strict, wiry, erect, pungent, smooth and polished ; sheaths long, smooth and shining ; ligules almost obsolete, reduced to a narrow transverse rim. Panicle 2–9 in. long, broad or narrow, lax ; branches few, in distant whorls or clusters, or in small specimens binate or solitary, sparingly divided, spreading, capillary, scabrid. Spikelets pale-green, about $\frac{1}{4}$ in. long, 3–6-flowered. Two outer glumes unequal, about $\frac{3}{4}$ the length of the flowering glumes above them, ovate-lanceolate, acute, membranous, 3-nerved, smooth or scabrid on the keel. Flowering glumes oblong-lanceolate to oblong-ovate, subacute or obtuse, prominently 5-nerved, minutely scaberulous, callus and base of keel with a tuft of long crisped silky hairs. Palea rather shorter than the glume, minutely ciliate on the keels. Anthers linear, about $\frac{1}{10}$ in. long.—*A. Cunn. Precur.* (1836) n. 264 ; *Raoul Choix* (1846) 39 ; *Benth. Fl. Austral.* vii (1878) 651 ; *Cheesem. Man. N.Z. Fl.* (1906) 907. P. australis *var.* laevis *Hook. f. Handb. N.Z. Fl.* (1864) 339 ; *Buch. N.Z. Grasses* (1880) t. 47. P. laevis *var.* filifolia *Hook. f. Fl. Nov. Zel.* i (1853) 307.

Var. **leioclada** *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 908. — Panicle-branches smooth. Spikelets larger, ⅓ in. long or more.

Var. **australis** *Benth. Fl. Austral.* vii (1878) 653.—Leaves rough and scabrous. Panicle very lax and spreading. Perhaps naturalized.

Var. **planifolia** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 58.—Dark-green. Sheaths of the leaves long, scaberulous ; blades flat, keel prominent.

NORTH AND SOUTH ISLANDS, STEWART ISLAND : The typical state abundant from the Upper Thames and Waikato southwards. Var. *leioclada :* Mount Egmont, *Petrie !* near Westport, *W. Townson !* Var. *australis :* Marua, near Whangarei, *H. Hawkins !* near Auckland, *T. F. C.* Var. *planifolia :* Cultivated specimens grown from seed brought from Antipodes Island, *Petrie !* Sea-level to 4500 ft. "*Tussock-grass.*"

Also in Australia and Tasmania. The most abundant grass through wide districts in the South Island, also plentiful in the elevated central portions of the North Island. Unfortunately, it is not relished by stock, and is seldom eaten, save in the absence of better food.

19. **P. Colensoi** *Hook. f. Handb. N.Z. Fl.* (1864) 340.—Culms densely tufted, branched at the base, slender, erect, quite smooth, pale whitish-green, 2–14 in. high. Leaves shorter than the culms, very narrow, filiform, the margins so strongly involute that the leaf is almost terete, acute, erect or curved, rigid and wiry, quite smooth, polished; sheaths long, pale, rigid, grooved, the lower persistent long after the blades have fallen; ligules very large and long, sheathing, membranous, hyaline. Panicle ½–2 in. long, broadly ovate, lax, few-flowered; branches few, usually binate, slender, capillary, scabrid, bearing 1–3 spikelets at the tip. Spikelets pale-green, compressed, ⅕–¼ in. long, 3–6-flowered. Two outer glumes unequal, reaching about ⅔-way up the flowering glumes above them, oblong-lanceolate, acute, 3-nerved, the lateral nerves short and faint, smooth. Flowering glumes oblong-ovate, subacute, faintly 5-nerved, smooth or nearly so, keel and surfaces in the lower half very sparsely silky-pubescent or quite glabrous, with no long tuft of crisped hairs as in *P. caespitosa*. Palea slightly shorter than the glume. Anthers long, linear, about $\frac{1}{12}$ in. long.—*Buch. N.Z. Grasses* (1880) t. 48B; *Cheesem. Man. N.Z. Fl.* (1906) 908.

Var. **intermedia** *Cheesem. Man. N.Z. Fl.* (1906) 908.—Taller, with more of the tussocky habit of *P. caespitosa*, 9–18 in. high. Ligules as in the typical state. Panicle larger, 2–3 in. long. Spikelets more numerous, larger, ⅓ in. long, but flowering glumes as in the type.—P. intermedia *Buch. N.Z. Grasses* (1880) t. 48A.

Var. **breviligulata** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 57.—Ligules very short or almost obsolete, not sheathing. Otherwise much as in the type.

North Island: Mountainous localities and dry elevated plains of the interior, from Moehau (Cape Colville) southwards, but rare and local to the north of Lake Taupo. South Island, Stewart Island: Plentiful throughout. Usually from 1000 to 5000 ft., but descends almost to sea-level in the south of Otago, and ascends to over 7000 ft. on Mount Egmont. Var. *intermedia*: Probably not uncommon from the Nelson Mountains southwards to Foveaux Strait, *Buchanan! T. Kirk! W. Townson! H. H. Allan! T. F. C.* Var. *breviligulata*.—North Island: Mount Egmont, *Petrie!* South Island: Not uncommon in mountain districts throughout, *Petrie!*

A very remarkable species. I have reunited Mr. Buchanan's *P. intermedia* with it, there being no differences save those of size and habit, in which respect the two forms pass into one another by insensible gradations. Professor Hackel also takes the same view. Small states of *P. caespitosa* can always be distinguished by the almost obsolete ligules and by the long crisped hairs on the callus of the flowering glume.

P. Colensoi is one of the most important of the indigenous pasture-grasses. It is eaten by all kinds of stock, and is a specially valuable sheep-grass in mountain districts.

20. **P. acicularifolia** *Buch. N.Z. Grasses* (1880) t. 49A.—Much branched at the base, forming compact leafy glaucous-green patches 2–6 in. across; branches short, curved, densely leafy. Culms very slender, almost filiform, smooth, naked for the greater part of their length, 2–6 in. high. Leaves imbricating on the branches, crowded, short, ⅙–½ in. long, involute and terete, curved, rigid, smooth, suddenly narrowed into an acute or acicular tip; sheaths short, pale, lax; ligules very long, sheathing, deeply 2-fid, membranous, hyaline, decurrent along the margins of the sheath. Panicle ½–1 in. long, broadly ovate, lax, of 3–10 spikelets; branches few, slender, capillary, scabrid. Spikelets compressed, about ¼ in. long, 3–6-flowered. Two outer glumes unequal, oblong-lanceolate, acute, 3-nerved, smooth or slightly scabrid above. Flowering glumes oblong-ovate, subacute, 5-nerved, densely villous with short silky hairs below the middle, minutely rough above,

P. antipoda Petrie sub. is. 2 478

callus sometimes with a tuft of crisped hairs. Palea almost as long as the glume, linear-oblong, silky on the keels. Anthers long, linear, about $\frac{1}{12}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 909.

South Island: Nelson—Mount Arthur, *A. Mackay!* Canterbury—Limestone rocks in the Broken River basin, *J. D. Enys! T. Kirk! T. F. C.* 2000–4000 ft.

Very closely allied to *P. Colensoi*, and chiefly distinguished by the peculiar habit, short rigid acicular leaves, and densely silky flowering glumes.

21. **P. pygmaea** *Buch. N.Z. Grasses* (1880) t. 50A.—Small, much branched, very densely tufted, forming compact rigid patches 2–4 in. diam. and $\frac{1}{2}$–1 in. high. Culms very short, clothed throughout with densely imbricating leaves. Leaf-blades very short, $\frac{1}{8}$–$\frac{1}{3}$ in. long, extremely rigid and coriaceous, folded, about $\frac{1}{20}$ in. broad when spread out, subacute, strongly grooved, quite smooth; ligules broad, thin. Panicle reduced to 1–3 spikelets; pedicels short, smooth. Spikelets about $\frac{1}{6}$ in. long, brownish-green, often tinged with purple, 3–5-flowered. Two outer glumes slightly unequal, oblong-lanceolate, acute, 3-nerved, quite smooth. Flowering glumes ovate, subacute, faintly 5-nerved, smooth, lower half clothed with short white silky hairs. Palea $\frac{1}{4}$ shorter than the glume, ciliate on the keels. Anthers long, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 909.

South Island: Otago—Summit of Mount Pisa, altitude 6000 ft., *Petrie!*

A very remarkable little species, quite unlike any other.

22. **P. Kirkii** *Buch. N.Z. Grasses* (1880) t. 51B.—Culms tufted, erect, compressed, smooth, leafy, 3–5-noded, 6–18 in. high. Leaves much shorter than the culms, erect, 1–4 in. long, $\frac{1}{15}$–$\frac{1}{6}$ in. broad, linear, gradually tapering to an acuminate point, flat, smooth or the margins scabrid above, striate; sheaths compressed, grooved, the uppermost long, often sheathing the greater part of the culm; ligules long, membranous, erect. Panicle oblong or oblong-ovate, lax, erect, 2–5 in. long; rhachis slender, flexuous, smooth or minutely scaberulous; branches in alternate pairs or in alternate fascicles of 3–5, unequal, slender, sparingly divided, smooth or scaberulous. Spikelets elliptic-oblong, compressed, green or purplish-green, $\frac{1}{6}$–$\frac{1}{4}$ in. long, 3–5-flowered. Two outer glumes unequal, $\frac{1}{2}$–$\frac{2}{3}$ the length of the whole spikelet, oblong-lanceolate, acute, 3-nerved, smooth or scabrid along the keel. Flowering glumes oblong-ovate, obtuse, prominently 5-nerved, smooth or minutely scabrid on the keel and nerves above, glabrous or rarely with a tuft of crisped hairs on the callus. Palea about $\frac{1}{4}$ shorter than the glume, linear-oblong, ciliate on the keels. Anthers linear-oblong, $\frac{1}{20}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 910; *Ill. N.Z. Fl.* ii (1914) t. 232. P. purpurea *T. Kirk in Trans. N.Z. Inst.* ix (1877) 500 (*name only*).

Var. **Mackayi** *Hack. MSS.*—Taller and stouter; leaves often $\frac{1}{4}$ in. broad. Spikelets larger, $\frac{1}{3}$ in. long. Flowering glumes often with a tuft of long crisped hairs on the callus. Anthers $\frac{1}{15}$ in. long.—P. Mackayi *Buch. N.Z. Grasses* (1880) t. 50A.

Var. **Collinsii** *Hack. MSS.*—Slender, pale-green, laxly tufted, 1–2 ft. high; nodes of the culm usually naked. Panicle 3–6 in. long, very lax; branches long, slender. Spikelets as in the type, but rather larger.—P. Collinsii *Kirk ex Petrie in Trans. N.Z. Inst.* xxviii (1896) 589 (*name only*).

North Island: Mount Egmont, *Petrie! T. F. C.;* Ruahine Mountains, *B. C. Aston!* Tararua Range, *H. H. Travers! T. P. Arnold!* South Island: Abundant in subalpine localities throughout. Var. *Collinsii:* Mount Fyffe (Marlborough), *T. Kirk!* Hooker Valley, *T. F. C.* 2000–5000 ft.

A variable plant. Buchanan's *P. Mackayi* looks different at first sight, from its larger spikelets and broader leaves, but is connected with the type by intermediate forms. On the Mount Arthur Plateau, Nelson, the two varieties can be seen to merge into one another. *P. Collinsii* is a taller and more slender plant, with a larger and laxer panicle, but the structure of the spikelets is the same as in the type. *P. Kirkii* is a valuable grass for all kinds of stock in cool elevated localities, and is well worth cultivation.

23. **P. Lindsayi** *Hook. f. Handb. N.Z. Fl.* (1864) 340.—Culms numerous, densely tufted, very slender, erect, quite smooth, leafy at the base, naked above, 3–12 in. high. Leaves much shorter than the culms, ½–3 in. long, very narrow, flat or involute, soft and flaccid, quite smooth, pale-green or bluish-green; sheaths short or the upper alone long, narrow, grooved; ligules oblong, membranous, hyaline. Panicle broadly ovate or oblong, erect, lax, 1–4 in. long; rhachis slender, smooth; branches rather distant, binate or ternate, spreading, very slender, capillary, smooth or scaberulous, simple or sparingly divided, bearing a few spikelets towards the tip. Spikelets $\frac{1}{10}$–$\frac{1}{8}$ in. long, ovate, brownish-green or silvery-brown, 4–6-flowered. Two outer glumes unequal, about ½ as long as the spikelet, oblong-ovate, subacute, 3-nerved, membranous. Flowering glumes broadly oblong, obtuse, faintly 5-nerved, silky throughout with short hairs, but no tuft of crisped hairs on the callus; margins white, membranous. Palea slightly shorter than the glume, ciliate on the keels. Anthers small, oblong, about $\frac{1}{40}$ in. long.—*Buch. N.Z. Grasses* (1880) t. 52; *Cheesem. Man. N.Z. Fl.* (1906) 910.

North Island: Hawke's Bay — Ruataniwha Plains, *Tryon!* South Island: Not uncommon from the south of Nelson to Foveaux Strait. Sea-level to 5000 ft.

A pretty and distinct species, easily recognized by its small size and slender delicate habit, lax panicle, small silvery-brown spikelets, and faintly nerved silky flowering glumes. Hooker describes the flowering glumes as glabrous and nerveless, but I do not find them so.

24. **P. incrassata** *Petrie in Trans. N.Z. Inst.* xxxiv (1902) 394.—Culms small, densely tufted, quite smooth and glabrous, leafy, 2–4 in. high. Leaves equalling or sometimes overtopping the culms, erect or slightly spreading, slender, smooth, flaccid, very narrow, almost setaceous, complicate when dry; sheaths rather lax, almost as long as the blade, grooved; ligules short, membranous, truncate. Panicle ½–1 in. long, lax, of 3–6 spikelets on rather long smooth pedicels. Spikelets ⅛–$\frac{1}{6}$ in. long, broadly oblong, rather turgid, purplish-brown, 3–4-flowered. Two outer glumes subequal, about ½ the length of the flowering glumes immediately above them, oblong, obtuse, 3-nerved, quite smooth. Flowering glumes broadly oblong, obtuse, prominently 5-nerved, quite smooth and glabrous. Palea almost as long as the glume, linear-oblong, minutely ciliate on the keels. Anthers oblong, minute, about $\frac{1}{50}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 911. P. Campbellensis *Petrie in Trans. N.Z. Inst.* 1 (1918) 211.

Auckland and Campbell Islands: Port Ross, *B. C. Aston, F. R. Chapman!* Campbell Island, *B. C. Aston.*

I have seen very few specimens of this species, and the above description will probably require modification when a larger series is obtained. It appears to be nearest to *P. exigua*, but the panicle is much more lax, the spikelets larger and more turgid, and the outer glumes are much shorter. I am unable to separate Mr. Petrie's *P. Campbellensis* from the type.

25. **P. exigua** *Hook. f. Handb. N.Z. Fl.* (1864) 338.—Culms densely tufted, small, slender, quite smooth and glabrous, leafy, 1–5 in. high. Leaves numerous, shorter than the culms or rarely equalling them, ½–3 in. long, very narrow, involute, setaceous, erect, soft and flaccid, smooth; sheaths lax, thin, grooved; ligules short, white, membranous. Panicle small, ¼–¾ in. long, rarely more, narrow, contracted, usually dense-flowered; branches few, short, erect. Spikelets few or many, green tinged with purplish-red, ovate, small, $\frac{1}{10}$–⅛ in. long, 2–3-flowered. Two outer glumes unequal, membranous, minutely scabrid on the upper part of the keel; lower oblong-lanceolate, acute, 1-nerved; upper larger and broader, ¾ the length of the whole spikelet, oblong, obtuse, 3-nerved. Flowering glumes broadly oblong with white membranous margins, obtuse, 5-nerved, smooth or minutely scaberulous on the keel above, quite glabrous at the base. Palea linear-oblong, glabrous. Anthers oblong, minute, about $\frac{1}{50}$ in. long.—*Buch. N.Z. Grasses* (1880) t. 50B; *Cheesem. Man. N.Z. Fl.* (1906) 911.

South Island: Canterbury—Mount Arrowsmith, *Cockayne* and *R. M. Laing;* Lake district, *Hector* and *Buchanan;* Mount Pisa, Hector Mountains, Mount Cardrona, *Petrie!* Humboldt Mountains, *Cockayne!* 3500–6000 ft.

26. **P. Maniototo** *Petrie in Trans. N.Z. Inst.* xxii (1890) 443.—Culms forming small compact tufts, slender, leafy below, naked and filiform above, smooth and glabrous, 1–3 in. high. Leaves much shorter than the culms, pale glaucous-green; blade ¼–¾ in. long, very narrow, filiform, involute and almost terete, grooved down the back, obtuse at the tip; sheaths broad, pale, membranous, grooved; ligules long, broad, hyaline, often bifid or irregularly lacerate. Panicle reduced to an oblong spike-like head ¼–⅓ in. long of 4–12 spikelets. Spikelets pale glaucous-green, about ⅙ in. long, ovate, 4–7-flowered. Two outer glumes subequal, ovate-oblong, acute, the lower 1-nerved, the upper 3-nerved with the lateral nerves faint. Flowering glumes ovate-oblong, obtuse, faintly 3–5-nerved, the lateral nerves sometimes obsolete, silky all over with very short crisped hairs. Palea shorter than the glume, linear-oblong, silky on the keels. Anthers oblong, very minute, about $\frac{1}{75}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 912.

South Island: Canterbury—Broken River basin, Mackenzie Plains, *T. F. C.;* Mount Arrowsmith, *Cockayne* and *R. M. Laing.* Otago—Dry plains in the interior, Kurow, Maniototo, Bendigo, Mount Pisa, *Petrie!* Lake Wanaka, *T. Kirk!* 1200–3000 ft.

27. **P. sclerophylla** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 30.—Forming small dense tufts. Culms stout, erect, rigid, compressed, leafy, 2–8 in. high. Leaves numerous towards the base of the culms and sheathing their whole length, much shorter than them, glaucous or greenish-grey, everywhere rough with minute projections; blade ½–2 in. long, narrow, folded, $\frac{1}{16}$–⅛ in. broad when spread out, rigid and coriaceous, acute or almost pungent, straight or curved, strongly grooved, quite glabrous; sheaths broader than the blade, pale, compressed, the upper 1 or 2 very long and sheathing the culm; ligules rather long, membranous. Panicle ¾–2 in. long, very narrow, contracted, dense, spiciform, pale whitish-green; branches numerous, short, erect. Spikelets numerous, small, about ⅛ in. long, 2–4-flowered. Two outer glumes subequal, about ⅔ the length of the whole spikelet, oblong-lanceolate, acute, 3-nerved, the lateral nerves faint.

27. P. buchanani Zotov. 73: 231.

Flowering glumes broadly oblong, obtuse, 5-nerved, margins white and membranous, surfaces very minutely rough, quite glabrous. Palea linear-oblong, glabrous. Anthers oblong, small, about $\frac{1}{40}$ in. long. Ripe grain adherent to the palea.—*Cheesem. Man. N.Z. Fl.* (1906) 912. P. albida *Buch. N.Z. Grasses* (1880) t. 50c. P. anceps *var.* alpina *Hook. f. Handb. N.Z. Fl.* (1864) 339.

South Island: Probably not uncommon on dry shingle slopes in alpine localities. Nelson—Mount Percival, *T. F. C.;* Mount Captain, *T. Kirk.* Canterbury—Mount Torlesse, *Berggren, Petrie!* mountains above the Broken River, *T. F. C.;* Mount Peel, *H. H. Allan!* Mount Dobson and Mount Darwin, *Haast;* Mount Cook district, *T. F. C.* Otago—Mount St. Bathan's, Mount Ida, Mount Kyeburn, *Petrie!* 3500–6000 ft.

A very peculiar and distinct little species, quite unlike any other.

Sprengel 1807-8. p.340.

28. **P. imbecilla** *Forst. f. Prodr.* (1786) n. 499 (*name only*).—Culms tufted, branched and decumbent at the base, ascending or erect above, weak, very slender, often filiform, quite smooth and glabrous, leafy, 3–14 in. high. Leaves shorter than the culms, very narrow, $\frac{1}{30}$–$\frac{1}{15}$ in. broad, flat, flaccid; sheaths narrow, smooth, grooved, the upper often long; ligules rather long, membranous. Panicle very lax and slender, 1–5 in. long; branches in alternate fascicles of 3–5 or in small specimens binate or solitary, long, spreading, capillary, minutely scaberulous. Spikelets on long pedicles, small, green, $\frac{1}{10}$–$\frac{1}{8}$ in. long, laxly 2–6-flowered. Two outer glumes unequal, often small, from $\frac{1}{3}$ to $\frac{1}{2}$ the length of the flowering glumes immediately above them, ovate or ovate-oblong, obtuse or subacute, 3-nerved. Flowering glumes often remote, oblong or broadly oblong, obtuse, faintly 3-nerved, or occasionally 5-nerved with the intermediate nerve on each side indistinct, smooth and glabrous, or slightly scabrid on the keel and sometimes on the nerves above, no tuft of hairs on the callus. Palea about $\frac{3}{4}$ the length of the glume, linear-oblong, ciliate on the keels. Anthers oblong, minute, about $\frac{1}{60}$ in. long.—*Spreng. Fl. Hal. Mant.* i, 33; *A. Cunn. Precur.* (1836) n. 263; *Raoul Choix* (1846) 39; *Hook. f. Fl. Nov. Zel.* i (1853) 306; *Handb. N.Z. Fl.* (1864) 337; *Buch. N.Z. Grasses* (1880) t. 53b; *Cheesem. Man. N.Z. Fl.* (1906) 913. Eragrostis imbecilla *Benth. Fl. Austral.* vii (1878) 643.

Var. **breviglumis** *Cheesem.*—Two outer glumes very unequal, the lower sometimes nearly obsolete. Other characters very much as in the type.—P. breviglumis *Hook. f. Fl. Antarct.* i (1844) 101; *Cheesem. Man. N.Z. Fl.* (1906) 913.

Var. **Matthewsii** *Hack. MSS.*—Taller, 10–20 in. high. Panicle larger, 4–8 in. long. Spikelets rather larger, 4–6-flowered. Flowering glumes closer, usually 5-nerved, but the intermediate nerves on each side often very faint.—P. Matthewsii *Petrie in Trans. N.Z. Inst.* xxxiv (1902) 392. P. breviculmis *Hook. f. Handb. N.Z. Fl.* (1864) 337 (*in part*).

North and South Islands, Stewart Island, Chatham Islands: Not uncommon in shaded places throughout. Sea-level to 4000 ft. Var. *breviglumis:* Auckland and Campbell Islands, *Hooker! T. Kirk! F. R. Chapman!* Var. *Matthewsii:* Not uncommon from North Canterbury southwards to Foveaux Strait.

As a species, *P. imbecilla* is well characterized by the slender flaccid habit, small spikelets with minute outer glumes, and obtuse glabrous flowering glumes, which are usually 3-nerved in the typical form, but generally 5-nerved in var. *Matthewsii.* It is said to occur in Australia. In the first edition of this work I maintained Hooker's *P. breviglumis* as a separate species; but the examination of additional specimens and the perusal of Petrie's paper "On *Poa breviglumis*" (Trans. N.Z. Inst. xlii (1910) 197) have convinced me that it cannot be separated as a species from *P. imbecilla.*

PUCCINELLIA Parl. H. Hal. i, 366. (1846)

See Allan & Jansen Trans. 69: 262. + 15: 256.

29. ATROPIS Rupr. 1853

Annual or perennial grasses. Leaves linear, flat or plicate or convolute; ligules hyaline. Spikelets 3- to many-flowered, narrow, laterally compressed or almost cylindric, in open or contracted panicles; rhachilla disarticulating above the two outer glumes and between the flowering glumes, glabrous, produced beyond the uppermost flower. Two outer glumes persistent, broad, empty, unequal, rounded on the back, 1–3-nerved. Flowering glumes broad, oblong, obtuse, rounded on the back, 5-nerved, nerves often obscure. Palea nearly as long as the flowering glume, 2-keeled. Lodicules 2, large, ovate, usually distinct. Stamens 3. Ovary glabrous; styles wanting; stigmas plumose. Grain enclosed in the hardened flowering glume and palea, oblong, almost semiterete; hilum small, basal, punctiform.

Sect p 163

A small genus of 15 or 20 species, mostly from the temperate regions of the Northern Hemisphere. It differs from *Poa* principally in the flowering glumes being rounded on the back, not keeled.

* Panicle contracted in flower, open in fruit.

6–18 in. high. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in., 5–9-flowered	1. *A. stricta.*

** Panicle contracted in both flower and fruit.

Small, very slender, 4–8 in. high, 2-noded. Spikelets $\frac{1}{3}$ in., 5–6-flowered	2. *A. antipoda.*
Slender, 4–14 in. high, 3–4-noded. Spikelets $\frac{1}{4}$ in., 4–5-flowered ..	3. *A. Walkeri.*
Stout, loosely tufted, 9–18 in. high, 4–5-noded. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in., 4–6-flowered	4. *A. Chathamica.*

1. **A. stricta** (orth f.) *Hack. MSS.*—Annual. Culms tufted, strict, erect, quite glabrous, leafy, 3–4-noded, the uppermost node below the middle, 6–18 in. high. Leaves sheathing almost the whole of the culm, narrow, setaceously involute, strict, erect, quite smooth; sheaths pale, lower rather lax; ligules ovate, membranous. Panicle slender, contracted when in flower, 3–6 in. long; branches very unequal, in distant fascicles of 2–5, strict, erect in flower, spreading in fruit, simple or sparingly branched. Spikelets alternate on the branchlets, narrow, almost terete, pale, $\frac{1}{4}$–$\frac{1}{3}$ in. long, 5–9-flowered. Two outer glumes very unequal, the lower narrow-ovate, acute, 1-nerved, not $\frac{1}{2}$ the length of the flowering glume above it; upper twice as long as the lower, subacute, 3-nerved. Flowering glumes oblong, obtuse and hyaline at the tips, distinctly 5-nerved, but the nerves disappearing below the tip, quite smooth and glabrous. Palea shorter than the glume, linear-oblong, ciliolate along the keels. Lodicules distinct. Anthers oblong, about $\frac{1}{40}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 914. Glyceria stricta *Hook. f. Fl. Nov. Zel.* i (1853) 304; *Handb. N.Z. Fl.* (1864) 336; *Fl. Tasm.* ii (1860) 123, t. 162B; *Benth. Fl. Austral.* vii (1878) 658; *Buch. N.Z. Grasses* (1880) t. 41A.

Var. **suborbicularis** *Hack. MSS.*—Flowering glume much broader than in the type, in outline almost orbicular. Leaves weaker and thinner.

NORTH AND SOUTH ISLANDS: Not uncommon in brackish-water marshes from the Bay of Islands southwards to the Bluff. Var. *suborbicularis:* Banks Peninsula, *R. M. Laing;* near Oamaru, *Petrie!* AUCKLAND ISLANDS: Enderby Island, *B. C. Aston!*

Also in Australia and Tasmania. The northern *A. distans* Griseb., which is closely allied to *A. stricta*, is naturalized in several localities. It is not nearly so strict, the leaves are flatter, the panicle not so contracted, and the spikelets are much smaller.

2. **A. antipoda** (*Petrie*) *in Subantarct. Is. N.Z.* (1909) 480.—Pale-green, tufted, leafy, 4–8 in. high. Culms numerous, strict, erect, smooth and glabrous, 2-noded, upper node placed near the middle of the culm. Leaves sheathing the culm as far as the panicle, and often including the lower part of it, strict, erect, complicate, or nearly flat, striate, narrowed into long attenuate points; sheaths long, lax, fissured to the base, rather broad, pale, smooth and glabrous; ligules oblong, membranous, lacerate at the tip. Panicle 2–3 in. long, narrow, contracted, pale whitish-green, not equalling the leaves; branches unequal, in fascicles of 2 or 3, erect, sparingly divided. Spikelets $\frac{1}{3}$ in. long, shortly pedicelled, 5–6-flowered. Two outer glumes unequal, about $\frac{1}{2}$ the length of the spikelet, narrow-lanceolate, acuminate, lower 1-nerved, upper 3-nerved. Flowering glumes narrow oblong-lanceolate, subacute, 5-nerved, the median nerve slightly excurrent, glabrous except for a few hairs on the callus. Palea slightly shorter than the flowering glume; margins ciliate.

Auckland Islands: *T. Kirk! B. C. Aston!* Antipodes Island: *B. C. Aston!*

This is closely allied to *A. Walkeri*, but appears to differ in the smaller size and more slender habit, 2-noded culm, and in the larger number of florets in the spikelets.

3. **A. Walkeri** *Cheesem. n. comb.*—Annual, pale whitish-green. Culms densely tufted, erect, quite glabrous, leafy, 3–4-noded, the uppermost node much above the middle, 4–14 in. high. Leaves sheathing the whole of the culm, strict, erect, complicate, striate; sheaths compressed, usually longer than the blades, grooved; ligules broad, membranous, hyaline, irregularly toothed at the tip. Panicle 2–6 in. long, erect, contracted, dense, pale whitish-green; branches in fascicles of 2–7, very unequal, short, smooth, erect. Spikelets numerous, sessile or shortly pedicelled, about $\frac{1}{4}$ in. long, 4–5-flowered. Two outer glumes slightly unequal, about $\frac{1}{2}$ the length of the whole spikelet; lower narrow, lanceolate, acute, 1-nerved, sometimes with a short lateral nerve on each side; upper broader and more obtuse, 3-nerved. Flowering glumes oblong or oblong-ovate, obtuse and hyaline at the tip, with sometimes an obscure notch on each side, 5-nerved, glabrous or slightly hairy on the back near the base. Palea as long as the glume, linear-oblong, minutely bidentate at the tip, ciliolate on the nerves. Lodicules distinct. Anthers linear-oblong, about $\frac{1}{20}$ in. long.—A. novae-zealandiae *Hack. in Man. N.Z. Fl.* (1906) 915; *Cheesem. Man. N.Z. Fl.* (1906) 915. Poa Walkeri *T. Kirk in Trans. N.Z. Inst.* vii (1885) 224. Glyceria novae-zealandiae *Petrie in Trans. N.Z. Inst.* xxxiii (1901) 329.

South Island: Brackish-water marshes on the south coast of Otago, *T. Kirk! Petrie!* Stewart Island: East coast, local, *T. Kirk!*

Easily distinguished from the preceding by the stouter habit, denser panicle with shorter branches, smaller pale whitish-green spikelets with fewer florets, much larger empty glumes, and narrower and more pointed flowering glumes.

4. **A. Chathamica** (*Cheesem.*) *n. sp.*—Tall, stout, loosely tufted, perfectly smooth and glabrous, 9–18 in. high. Culms erect or decumbent at the base, 4-noded, the upper node placed about the middle; innovation-shoots intravaginal. Leaves numerous, those at the base short and scale-like, membranous, without any lamina; cauline leaves sheathing the whole culm and the greater part of the panicle, perfectly smooth and glabrous, pale whitish-green, folded, grooved, tip cartilaginous, subobtuse; sheaths very large and broad, longer than the blades, split to the base, compressed,

deeply striate; ligules broad, transversely oblong, membranous. Panicle narrow-linear, 2–6 in. long, rigid, erect, glabrous; branches few, unequal, solitary or 2-nate, more rarely 3-nate, erect, often almost appressed to the rhachis. Spikelets $\frac{1}{3}$–$\frac{1}{4}$ in. long, narrow-lanceolate, 4–6-flowered. Two outer glumes unequal, the longer one about $\frac{1}{3}$ the length of the spikelet, lanceolate, 3–nerved; the shorter broader, 1-nerved. Flowering glume oblong-ovate, subacute, faintly 3-nerved, glabrous, or a fine tuft of silky hairs on the callus. Palea nearly as long as the glume, margins ciliate.

CHATHAM ISLANDS: Exact locality not stated, *F. A. D. Cox!*

This appears to be a distinct species, easily recognized by its stout loosely tufted habit, long narrow panicle, and narrow many-flowered spikelets.

30. **FESTUCA** Linn. 1735.

Perennial or rarely annual grasses. Leaves flat or complicate or convolute, often setaceous; ligules scarious. Spikelets 2- to many-flowered, arranged in open or contracted often unilateral panicles; rhachilla disarticulating above the two outer glumes and between the flowering glumes. Two outer glumes unequal or subequal, empty, persistent, more or less keeled, 1–3-nerved. Flowering glumes lanceolate, acute or acuminate or awned, rounded on the back or slightly keeled towards the tip, herbaceous, 5–7-nerved; awn from the tip or close to it, straight; callus glabrous or nearly so. Palea 2-keeled, more or less 2-toothed, scabrid or ciliolate along the keels. Lodicules 2. Stamens 3. Ovary glabrous or minutely hairy at the tip; styles distinct, very short; stigmas plumose. Grain enclosed within the slightly hardened flowering glume and palea and often adherent to the latter, oblong, concave or grooved in front; hilum long, linear.

A genus of about 120 species, mainly found in the temperate regions of the Northern Hemisphere, not so abundant in the South Temperate Zone, absent in the tropics except on high mountains. It differs from *Atropis* in the long linear hilum, and from *Poa* in the same character and in the flowering glumes being more or less rounded on the back and often awned.

* Flowering glumes not awned.

Culms 1½–3 ft., forming dense hard tussocks. Panicle 2–9 in. Spikelets turgid, ½–¾ in. long .. .. 1. *F. littoralis.*

** Flowering glumes awned; awn much shorter than the glume.

† Spikelets 4–8-flowered.

Culms 1–2 ft., forming dense tussocks. Leaves cylindric, scabrid. Spikelets ½ in. .. .. 2. *F. novae-zealandiae.*

Culms 1–2 ft., not forming tussocks. Leaves complicate, smooth. Spikelets large, ½–⅔ in. .. .. .. 3. *F. Matthewsii.*

Culms 9–18 in., few-noded, erect. Leaves flat or involute, smooth. Spikelets ¼–⅓ in. .. .. 4. *F. rubra.*

Culms 6–15 in., many-noded, decumbent at the base. Leaves more or less secund .. .. 5. *F. multinodis.*

†† Spikelets 2–3-flowered.

Culms 9–12 in., densely tufted. Leaves complicate, terete, strict, erect .. .. 6. *F. erecta.*

*** Flowering glumes awned; awn as long or longer than the glume.

Culms 6–18 in., densely tufted, stoloniferous. Leaves soft, pliant, terete. Panicle narrow, spiciform. Spikelets 3–5-flowered .. .. 7. *F. Coxii.*

1. **F. littoralis** *Labill. Pl. Nov. Holl.* i (1806) 22, t. 27.—Forming dense hard tussocks of a pale yellow-green colour. Culms branched at the base, erect, rigid, smooth and polished, 1½–3 ft. high. Leaves longer or shorter than the culms, narrow, so strongly involute that the blade is terete, erect, rigid and pungent-pointed, quite smooth and polished; sheaths pale, grooved; ligules short. Panicle 2–9 in. long, narrow, dense and spike-like; rhachis stout, angled, grooved; branches short, erect, usually few-flowered; pedicels short, pilose. Spikelets large, broad, flattened or somewhat turgid, ½–¾ in. long, 4–7-flowered, pale yellowish-green. Two outer glumes subequal, more than ½ as long as the spikelet, keeled, lanceolate, acuminate, 3–5-nerved, glabrous. Flowering glumes oblong-lanceolate, rounded on the back at the base, keeled above, 5–7-nerved, acute or very minutely notched at the tip, the central nerve stout and slightly protruding in the notch, equally minutely hairy all over, base of glume, callus, and rhachilla more or less densely clothed with short hairs. Palea lanceolate, ciliolate along the keels. Grain narrow-oblong, almost terete; hilum linear, very short.—*A. Rich. Fl. Nouv. Zel.* (1832) 123; *Hook. f. Fl. Tasm.* ii (1860) 138; *Handb. N.Z. Fl.* (1864) 341; *Buch. N.Z. Grasses* (1880) t. 54; *Cheesem. Man. N.Z. Fl.* (1906) 917. Schedonorus littoralis *Beauv. Agrost.* (1812) 99; *A. Cunn. Precur.* (1836) n. 259; *Raoul Choix* (1846) 39; *Hook. f. Fl. Nov. Zel.* i (1853) 310.

North and South Islands, Stewart Island, Chatham Islands: Abundant in sandy and rocky places near the shore. Also common on the coasts of temperate Australia.

Var. triticoides *Benth. Fl. Austral.* vii (1878) 656; *Buch. N.Z. Grasses* (1880) t. 54 (*left-hand figure*). F. triticoides *Steud. Syn. Gram.* (1855) 315 is not uncommon on many parts of the New Zealand coasts, and usually can be easily recognized by its greater size, larger spikelets, and 7-nerved flowering glumes. But Professor Hackel has pointed out that the differences are inconstant and not of sufficient weight to maintain it as a variety.

2. **F. novae-zealandiae** *Cockayne in Trans. N.Z. Inst.* xlviii (1916) 178.—Forming dense tussocks 1–2 ft. high. Culms slender, erect, scabrid, 3-noded. Leaves shorter than the culms or almost equalling them, strict, rigid, erect, very narrow, cylindric, setaceous, sharply acute or almost pungent, rough with minute scabrid points; sheaths fissured to the base, quite smooth and glabrous; ligules evidently biauricled, glabrous. Panicle linear-oblong, contracted but somewhat lax, 2–5 in. long; lower branches binate, 3–6-spiculate. Spikelets elliptic, ⅓ in. long, laxly 5–7-flowered. Two outer glumes linear-lanceolate, acuminate, margins and keel scaberulous. Flowering glumes narrow-lanceolate, mucronate or shortly awned at the tip.—F. ovina *var.* novae-zealandiae *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 917; *Ill. N.Z. Fl.* ii (1914) t. 233. F. duriuscula *Hook. f. Fl. Nov. Zel.* i (1853) 309, *and Handb. N.Z. Fl.* (1864) 341 (*in part, but not of Linn.*).

North Island: Kaimanawa Mountains, *B. C. Aston!* Ruahine Mountains, *A. Hamilton!* South Island: Not uncommon in mountain districts throughout. Banks Peninsula, *R. M. Laing!* 1000–4000 ft.

I agree with Dr. Cockayne in considering that this plant should be treated as worthy of the rank of a species, a course which Professor Hackel was inclined to adopt when he first described it. It occupies a prominent place in large areas of the eastern slopes of the Southern Alps, and is of considerable economic importance.

3. **F. Matthewsii** *Cheesem. n. sp.*—Culms erect, quite smooth and glabrous, 12–24 in. high, 2-noded; upper node about the middle of the culm. Innovation-shoots few-leaved, elongate. Leaves almost equalling the culms,

narrow-linear, complicate, acute at the tip, furnished at the base with a brown pulvinate callus, glabrous without, ribbed when dry, puberulous within, 5-nerved, hexagonal in transverse section ; sheaths rather lax, open, quite smooth ; ligules 2-lobed, lobes acute, ciliolate. Panicle 3–6 in. long, ovate-oblong, lax, spreading, nodding ; rhachis and branches scabrid ; the latter binate, naked at the base, 1–3-spiculate at the top. Spikelets large, ovate-lanceolate, 5–7-flowered, $\frac{1}{2}$–$\frac{2}{3}$ in. long, dense-flowered, the upper shortly pedicelled, the remainder long-pedicelled. Two outer glumes unequal, lanceolate, acute, smooth. Flowering glumes linear-lanceolate, acute, narrowed into a rather long awn. Palea as long as or longer than the flowering glume, subulately bidentate ; keels scaberulous.—F. ovina *var.* Matthewsii *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 918.

South Island : Otago—Mount Bonpland, *H. J. Matthews!*

This appears to me to be a perfectly distinct species, easily recognized by the large spikelets and curious pulvinate callus at the base of the leaf-blades.

4. **F. rubra** *Linn. Sp. Plant.* (1753) 74.—Culms 9–18 in. high, laxly or densely tufted, erect or geniculate at the base, smooth, striate, 2-noded ; innovation-shoots both intravaginal and extravaginal, the extravaginal ones ascending or stoloniferous and creeping. Leaves 3–6 in. long, narrow, those of the innovation-shoots and sometimes of the culms setaceous, but frequently the culm-leaves are broader and flat or involute when dry, 3–7-nerved, smooth, obtuse or subacute at the tip ; sheaths of the innovation-shoots tight, smooth, closed almost to the mouth ; ligules very short, glabrous, not auricled or obscurely so. Panicle very variable, 1–5 in. long, contracted, usually rather dense, erect or nodding, often secund ; rhachis angled, scabrid ; branches solitary or the lowest binate, divided almost from the base, scaberulous. Spikelets elliptic-lanceolate to oblong, $\frac{1}{4}$–$\frac{1}{2}$ in. long, laxly 4–8-flowered. Two outer glumes unequal ; lower lanceolate, acuminate, 1-nerved ; upper larger, ovate-lanceolate, 3-nerved. Flowering glumes oblong-lanceolate, involute and rounded on the back, faintly 5-nerved, shortly awned ; awn slender, scaberulous. Palea as long as the glume, linear-oblong, ciliolate on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 918. F. duriuscula *Hook. f. Fl. Nov. Zel.* i (1853) 309 ; *Handb. N.Z. Fl.* (1864) 341 (*for the most part, but not of Linn.*).

North and South Islands, Stewart Island : Abundant from the East Cape and the Upper Waikato southwards. Sea-level to 4500 ft.

According to Professor Hackel, this constitutes the greater part of the *F. duriuscula* of the "Flora Novae-Zelandiae" and the Handbook, the true *F. duriuscula* probably not existing in an indigenous state in New Zealand. It is very closely allied to *F. ovina*, differing mainly in the innovation-shoots being frequently stoloniferous, and usually both extravaginal and intravaginal, and in their sheaths being closed almost to the mouths ; also in the ligules not being auricled, and in the stem-leaves being usually broader and flatter than those on the innovation-shoots. It has considerable value as a sheep-grass, and is often sown on sheep-runs. From that fact it is doubtful whether some of the European forms that can now be readily collected even in remote districts may not have been introduced. Of some varieties, however, there is no reason to doubt their nativity. *F. rubra* has a wide range in Europe and northern Asia.

5. **F. multinodis** *Petrie and Hack. in Trans. N.Z. Inst.* xliv (1912) 186.—Culms densely tufted, decumbent or geniculate below, ascending above, branched and sometimes excessively so, leafy, 6–15 in. long, very slender, terete, many-noded ; innovation-shoots extravaginal. Leaves numerous, 10–12 to a culm, shorter than the culms, more or less secund,

smooth and glabrous, involute, setaceous, acute ; sheaths long, fissured to the base, not striate ; ligules short, glabrous. Panicle 1¼–2½ in. long, ovate-lanceolate, usually rather dense and compact ; rhachis and branches glabrous and angled ; branches solitary or the lower binate ; divisions few, glabrous. Spikelets ovate-lanceolate, ¼–⅓ in. long, shortly pedicelled or almost sessile, 4–8-flowered. Two outer glumes unequal ; lower lanceolate, acuminate, 1-nerved ; upper larger, ovate-lanceolate, 3-nerved. Flowering glumes rounded on the back, oblong-lanceolate, acute, faintly 5-nerved. Awn variable, sometimes short and almost wanting, at other times well developed. Palea as long as the flowering glume, linear-oblong, the keels smooth.

North Island : Shores of Port Nicholson, and rocky slopes of Cook Strait, *T. Kirk ! B. C. Aston ! D. Petrie ! T. F. C.* South Island : Awatere Valley and Banks Peninsula, *Cockayne !*

6. **F. erecta** *D'Urv. in Mem. Soc. Linn. Paris*, iv (1826) 601.—Perennial, densely tufted, 8–12 in. high. Culms strict, erect, 2-noded or rarely 3-noded, the lowest node near the base, quite smooth and glabrous. Leaves usually overtopping the culms, narrow, strict, erect, quite glabrous ; sheaths rather lax, much broader than the blades, ⅛–⅓ in. diam., pale, thin and membranous, striate ; blades narrow, $\frac{1}{15}$–$\frac{1}{12}$ in. across, complicate and appearing almost terete, quite smooth, faintly 10–12-ribbed on the outside, the ribs much more prominent on the inner face, which is usually furnished with short stiff hairs ; apex of leaf rigid and pungent. Panicle contracted, narrow, erect, 2½–4 in. long ; rhachis angular, finely scabrid [illegible] branches usually solitary, or the lower a little remote ;

Festuca
Man.

N.Z. Fl. (1906) 919 ; *Petrie in Subantarct. . .*

Macquarie Island : Rocks near the sea, not uncommon, *Dr. Scott ! A. Hamilton ! H. Hamilton !*

Also found in Fuegia, Falkland Islands, and Kerguelen. But for its absence from the New Zealand Subantarctic Islands it might be included in the "circumpolar species" that are found throughout the ring or zone of widely separated islands that girdle the Antarctic seas within the parallels of 45° S. to 60° S. I am indebted to Dr. Stapf, of the Kew Herbarium, for comparing some of Mr. Hamilton's specimens with Fuegian examples, and for informing me that they quite correspond.

7. **F. Coxii** *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 919.—Rhizome stout, creeping. Culms densely tufted, branched at the base, erect or slightly geniculate, slender, smooth, leafy, 6–18 in. high. Leaves numerous, longer than the culms, slender, soft, pliant, the margins so much involute that the leaf is terete, smooth on the back, midrib prominent on the inner face ; sheaths rather lax, thin, smooth, striate, open to the base ; ligules very short, truncate, ciliolate at the tip. Panicle 2–3 in. long, narrow, rather dense, often reduced to a simple raceme or spike, or with 2–3-spiculate branches in the lower part ; rhachis stout, angled, scabrid ; branches or pedicels very short, stout, scabrid, the upper spikelets nearly sessile.

narrow-linear, complicate, acute at the tip, furnished at the base with a brown pulvinate callus, glabrous without, ribbed when dry, puberulous within, 5-nerved, hexagonal in transverse section ; sheaths rather lax, open, quite smooth ; ligules 2-lobed, lobes acute, ciliolate. Panicle 3–6 in. long, ovate-oblong, lax, spreading, nodding ; rhachis and branches scabrid ; the latter binate, naked at the base, 1–3-spiculate at the top. Spikelets large, ovate-lanceolate, 5–7-flowered, $\frac{1}{2}$–$\frac{2}{3}$ in. long, dense-flowered, the upper shortly pedicelled, the remainder long-pedicelled. Two outer glumes unequal, lanceolate, acute, smooth. Flowering glumes linear-lanceolate, acute, narrowed into a rather long awn. Palea as long as or longer than the flowering glume, subulately bidentate ; keels scaberulous.—F. ovina *var.* Matthewsii *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 918.

South Island : Otago—Mount Bonpland, *H. J. Matthews!*

This appears to me to be a perfectly distinct species, easily recognized by the large spikelets and curious pulvinate callus at the base of the leaf-blades.

4. **F. rubra** *Linn. Sp. Plant.* (1753) 74.—Culms 9–18 in. high, laxly or densely tufted, erect or geniculate at the base, smooth, striate, 2-noded ; innovation-shoots both intravaginal and extravaginal, the extravaginal ones ascending or stoloniferous and creeping. Leaves 3–6 in. long, narrow, those of the innovation-shoots and sometimes of the culms setaceous, but frequently the culm-leaves are broader and flat or involute when dry, 3–7-nerved, smooth, obtuse or subacute at the tip ; sheaths of the innovation-shoots tight, smooth, closed almost to the mouth ; ligules very short, glabrous, not auricled or obscurely so. Panicle very variable, 1–5 in. long, usual branc lous. Two larger involu slend on th *Fl. N but no*

vol. 57, p. 64. (Ckn. & Allan).

North and South Islands, Stewart Island : Abundant from the East Cape and the Upper Waikato southwards. Sea-level to 4500 ft.

According to Professor Hackel, this constitutes the greater part of the *F. duriuscula* of the "Flora Novae-Zelandiae" and the Handbook, the true *F. duriuscula* probably not existing in an indigenous state in New Zealand. It is very closely allied to *F. ovina*, differing mainly in the innovation-shoots being frequently stoloniferous, and usually both extravaginal and intravaginal, and in their sheaths being closed almost to the mouths ; also in the ligules not being auricled, and in the stem-leaves being usually broader and flatter than those on the innovation-shoots. It has considerable value as a sheep-grass, and is often sown on sheep-runs. From that fact it is doubtful whether some of the European forms that can now be readily collected even in remote districts may not have been introduced. Of some varieties, however, there is no reason to doubt their nativity. *F. rubra* has a wide range in Europe and northern Asia.

5. **F. multinodis** *Petrie and Hack. in Trans. N.Z. Inst.* xliv (1912) 186.—Culms densely tufted, decumbent or geniculate below, ascending above, branched and sometimes excessively so, leafy, 6–15 in. long, very slender, terete, many-noded ; innovation-shoots extravaginal. Leaves numerous, 10–12 to a culm, shorter than the culms, more or less secund,

smooth and glabrous, involute, setaceous, acute ; sheaths long, fissured to the base, not striate ; ligules short, glabrous. Panicle 1¼–2½ in. long, ovate-lanceolate, usually rather dense and compact ; rhachis and branches glabrous and angled ; branches solitary or the lower binate ; divisions few, glabrous. Spikelets ovate-lanceolate, ¼–⅓ in. long, shortly pedicelled or almost sessile, 4–8-flowered. Two outer glumes unequal ; lower lanceolate, acuminate, 1-nerved ; upper larger, ovate-lanceolate, 3-nerved. Flowering glumes rounded on the back, oblong-lanceolate, acute, faintly 5-nerved. Awn variable, sometimes short and almost wanting, at other times well developed. Palea as long as the flowering glume, linear-oblong, the keels smooth.

North Island : Shores of Port Nicholson, and rocky slopes of Cook Strait, *T. Kirk ! B. C. Aston ! D. Petrie ! T. F. C.* South Island : Awatere Valley and Banks Peninsula, *Cockayne !*

6. **F. erecta** *D'Urv. in Mem. Soc. Linn. Paris*, iv (1826) 601.—Perennial, densely tufted, 8–12 in. high. Culms strict, erect, 2-noded or rarely 3-noded, the lowest node near the base, quite smooth and glabrous. Leaves usually overtopping the culms, narrow, strict, erect, quite glabrous ; sheaths rather lax, much broader than the blades, ⅕–⅓ in. diam., pale, thin and membranous, striate ; blades narrow, $\frac{1}{15}$–$\frac{1}{12}$ in. across, complicate and appearing almost terete, quite smooth, faintly 10–12-ribbed on the outside, the ribs much more prominent on the inner face, which is usually furnished with short stiff hairs ; apex of leaf rigid and pungent. Panicle contracted, narrow, erect, 2½–4 in. long ; rhachis angular, finely scabrid on the angles ; branches usually solitary, or the lower a little remote ; lateral branches very short. Spikelets ⅔–⅘ in. long including the awns, 2–3-flowered ; two outer glumes unequal, lanceolate, acuminate, from ¾–⅘ the length of the entire spikelet ; lower faintly 3-nerved, upper distinctly 3-nerved. Flowering glumes lanceolate, rounded on the back, faintly scaberulous, rather thin, distinctly 5-nerved, narrowed into a short stiff awn. Palea shorter than the glume, narrow-lanceolate, scaberulous on the keels. Grain narrow-obovoid ; hilum long, linear.—*Cheesem. Vascl. Fl. Macquarie Is.* (1919) 37 ; *Hook. f. Fl. Antarct.* ii (1847) 384. Festuca contracta *T. Kirk in Trans. N.Z. Inst.* xxvii (1898) 353 ; *Cheesem. Man. N.Z. Fl.* (1906) 919 ; *Petrie in Subantarct. Is. N.Z.* ii (1909) 479.

Macquarie Island : Rocks near the sea, not uncommon, *Dr. Scott ! A. Hamilton ! H. Hamilton !*

Also found in Fuegia, Falkland Islands, and Kerguelen. But for its absence from the New Zealand Subantarctic Islands it might be included in the "circumpolar species" that are found throughout the ring or zone of widely separated islands that girdle the Antarctic seas within the parallels of 45° S. to 60° S. I am indebted to Dr. Stapf, of the Kew Herbarium, for comparing some of Mr. Hamilton's specimens with Fuegian examples, and for informing me that they quite correspond.

7. **F. Coxii** *Hack. in Cheesem. Man. N.Z. Fl.* (1906) 919.—Rhizome stout, creeping. Culms densely tufted, branched at the base, erect or slightly geniculate, slender, smooth, leafy, 6–18 in. high. Leaves numerous, longer than the culms, slender, soft, pliant, the margins so much involute that the leaf is terete, smooth on the back, midrib prominent on the inner face ; sheaths rather lax, thin, smooth, striate, open to the base ; ligules very short, truncate, ciliolate at the tip. Panicle 2–3 in. long, narrow, rather dense, often reduced to a simple raceme or spike, or with 2–3-spiculate branches in the lower part ; rhachis stout, angled, scabrid ; branches or pedicels very short, stout, scabrid, the upper spikelets nearly sessile.

Spikelets about ¾ in. long with the awns, laxly 3–5-flowered. Two outer glumes unequal, from ½ to ¾ the length of the whole spikelet, narrowed into long acuminate scabrid points; lower linear, 1-nerved; upper longer, narrow-lanceolate, 3-nerved. Flowering glumes oblong-lanceolate, firm, rounded on the back, concave, faintly 5-nerved, gradually narrowed into a terete scabrid awn as long or longer than the glume, surface densely minutely scabrid, callus glabrous. Palea as long as the glume, deeply 2-fid, serrulate along the keels. Grain linear-oblong, deeply grooved; hilum ⅘ the length of the grain.—Agropyrum Coxii *Petrie in Trans. N.Z. Inst.* xxxiv (1902) 395; *Cockayne Veg. N.Z.* (1921) t. 85.

CHATHAM ISLANDS: Common on rocks and sands near the shore, *F. A. D. Cox* and *Cockayne!*

A distinct species, well marked by the peculiar habit, narrow spike-like panicles, short stout pedicels, narrow awned empty glumes, and by the long-awned flowering glumes.

31. **BROMUS** Linn. 1735.

Annual or perennial grasses, of very various habit. Leaves flat, often flaceid; ligules membranous. Spikelets laterally compressed, 4- to many-flowered, arranged in a lax or contracted panicle, rarely reduced to a raceme; rhachilla disarticulating above the two outer glumes and between the flowering glumes. Two outer glumes unequal, empty, persistent, 1–7-nerved. Flowering glumes lanceolate to oblong, rounded on the back or keeled, 5–9-nerved, usually 2-toothed at the apex, awned from between the teeth or rarely from below them. Palea 2-toothed, ciliolate or scabrid on the keels. Lodicules 2, oblong or lanceolate, entire or lobed. Stamens usually 3. Ovary oblong or obovoid, furnished with a 2–3-lobed hairy cushion-like appendage at the summit; styles short, placed laterally on the appendage; stigmas plumose. Grain linear or oblong, furrowed, adherent to the palea; hilum long, narrow-linear.

Species 40 or 50, most abundant in the North Temperate Zone and in South America, rare on the high mountains of the tropics. The single indigenous species is a common Australian plant." (pas. not only in N.Z.)"

1. **B. arenarius** *Labill. Pl. Nov. Holl.* i (1806) 23, t. 28.—Annual, everywhere villous with soft spreading hairs. Culms slender, erect or ascending, sometimes geniculate near the base, leafy. Leaves 2–5 in. long, linear, flat, flaccid, withering early; sheaths close, thin, strongly striate; ligules hyaline, fimbriate at the tip. Panicle 2–6 in. long, flaccid, nodding; rhachis slender, pilose; branches in fascicles of 3–7, slender, capillary, spreading and flexuous, the longest 1½ in. long, bearing 1–3 spikelets on very slender capillary pedicels. Spikelets about ⅔ in. long without the awns, 1¼–1½ in. long with them, 4–8-flowered. Two outer glumes unequal, not ½ the length of the spikelet, villous with long hairs, acuminate, margins hyaline; the lower narrow-lanceolate, 3-nerved, but the lateral nerves often short and faint; upper oblong-lanceolate, 5–7-nerved. Flowering glumes oblong-lanceolate, thin and membranous, hyaline on the margins, strongly 7-nerved, villous, deeply 2-fid at the tip; awn as long or longer than the glume, straight, scabrid, from the back just below the notch. Palea narrow, shorter than the glume, ciliate on the keels.—*Hook. f. Fl. Nov. Zel.* i (1853) 310; *Handb. N.Z. Fl.* (1864) 341; *Benth. Fl. Austral.* vii (1878) 661; *Buch. N.Z. Grasses* (1880) t. 56A; *Cheesem. Man. N.Z. Fl.* (1906) 920. B. australis *R. Br. Prodr.* (1810) 178; *A. Cunn. Precur.* (1836) n. 358; *Raoul Choix* (1846) 39.

North Island: Rocky and sandy places near the sea, abundant from the North Cape to the East Cape and Taranaki, local farther south, rare inland, but occurring at Lake Rotorua and elsewhere. South Island: Cape Farewell, *T. Kirk!* Also not uncommon in Australia.

Several species of *Bromus* from the Northern Hemisphere are now firmly established as naturalized plants, the most abundant being *B. mollis*, a rather small species with a compact ovoid panicle and turgid spikelets; and *B. sterilis*, with a lax drooping panicle and large long-awned spikelets 2 in. long with the awns.

32. **AGROPYRUM** Gaertn.

Annual or perennial grasses. Leaves flat or convolute; ligules scarious. Spikelets more or less laterally compressed, 3- to many-flowered, solitary and sessile, distichously placed in the alternate hollows of the continuous or jointed rhachis of a simple spike, one face of the spikelet next the rhachis; rhachilla disarticulating above the two outer glumes and usually between the flowering glumes. Two outer glumes subequal or unequal, empty, persistent, lanceolate or linear. Flowering glumes more or less rigid and coriaceous, rounded on the back or keeled above, 5–7-nerved, awned or awnless. Palea rather shorter than the glume, sharply 2-keeled, ciliate on the keels. Lodicules 2, oblique or unequally lobed, entire or ciliate. Stamens 3. Ovary villous at the top; styles very short; stigmas plumose. Grain narrow, compressed at the back, often adherent to the palea; hilum as long as the grain.

Species about 35, found in almost all temperate countries, but most abundant in Europe and north Asia. Of the 4 species found in New Zealand, 1 extends to Australia, the remaining 3 are endemic.

* Awn short, never more than ½ the length of the flowering glume.

Spikelets 1 in., 6–12-flowered. Awn very short, sometimes wanting.. 1. *A. multiflorum.*

Spikelets ½ in., 2–4-flowered. Awn from ⅓ to ½ the length of the flowering glume .. .. 2. *A. aristatum.*

** Awn very long, from 3 to 5 times the length of the flowering glume.

Spikelets 1½–3 in. long with the awns; awn usually slender .. 3. *A. scabrum.*

1. **A. multiflorum**, *T. Kirk in Trans. N.Z. Inst.* xxix (1897) 530.—Perennial. Culms densely tufted, branched, decumbent or almost prostrate at the base, erect above, quite smooth and glabrous, leafy, 1–2 ft. high. Leaves 3–8 in. long, about ⅙ in. broad, flat or slightly convolute when dry, tapering from the base upwards, somewhat rigid and coriaceous, prominently striate, rough above, often glaucous; sheaths tight, pale, grooved; ligules short, truncate, membranous. Spike straight, erect, 3–6 in. long, of 6–12 spikelets; rhachis pubescent on the angles. Spikelets about 1 in. long, close or somewhat distant, erect, appressed to the rhachis, 6–12-flowered. Two outer glumes small, unequal, lanceolate, acuminate, 3–7-nerved. Flowering glumes oblong-lanceolate when spread out, convolute, smooth and rounded on the back below, scabridly keeled above, 7–9-nerved, coriaceous, acute or mucronate or produced into a short awn of varying length. Palea sharply keeled and folded, ciliolate on the keels.—*Cheesem. Man. N.Z. Fl.* (1906) 921. Triticum multiflorum *Banks and Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 311; *Handb. N.Z. Fl.* (1864) 342; *Buch. N.Z. Grasses* (1880) t. 56B. T. repens *A. Rich. Fl. Nouv. Zel.* (1832) 138; *A. Cunn. Precur.* (1836) n. 261; *Raoul Choix* (1846) 39 (*not of Linn.*).

Var. **longisetum** *Hack. MSS.*—Awn longer, sometimes half the length of the flowering glume.

North Island: Not uncommon in lowland districts throughout, especially near the coast. South Island: Queen Charlotte Sound, *Banks* and *Solander;* near Nelson, *T. F. C.;* Canterbury, *J. B. Armstrong;* Banks Peninsula, *T. Kirk.*

A variable plant in the size of the spikelets, number of flowering glumes, and the extent to which the awn is developed.

2. **A. aristatum** *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 234.—Culms laxly tufted, very slender, weak, decumbent at the base, erect above, sparingly leafy, 1–2½ ft. high. Leaves much shorter than the culms, $\frac{1}{15}$–$\frac{1}{6}$ in. broad, flat, flaccid, striate, minutely rough to the touch, glabrous or sparingly villous; sheaths long, tight, softly villous or the upper ones almost glabrous; ligules short, truncate, erose. Spike 2–5 in. long, slender, erect or inclined, often interrupted below, of 9–18 spikelets; rhachis compressed, scabrid on the angles. Spikelets bluish-green, ½ in. long, 2–4-flowered. Two outer glumes about ½ the length of the spikelet, subequal, linear-lanceolate, 3–5-nerved, gradually narrowed into a scabrid acuminate point or awn ⅓–½ the length of the glume. Flowering glumes lanceolate, rounded on the back, smooth and coriaceous, 5-nerved, sometimes minutely 2-toothed at the tip, narrowed into a short scabrid awn about ⅓ the length of the glume. Palea shorter than the glume, linear-oblong, coriaceous, ciliolate on the keels.—A. Enysii *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 352; *Cheesem. Man. N.Z. Fl.* (1906) 922. Asprella aristata *Petrie in Trans. N.Z. Inst.* xxvii (1894) 272.

South Island: Canterbury—Slopes of Mount Torlesse and Broken River, *J. D. Enys! Petrie! T. F. C.;* Bealey River, *T. Kirk!* Poulter River, *Cockayne!* Southern Alps, *N. T. Carrington!* 2500–4500 ft.

A very distinct species, at once recognized by the weak habit, flat membranous leaves, narrow spike, and few-flowered spikelets. Very similar in habit to *Asperella gracilis*, and easily mistaken for it on a cursory inspection, but the structure of the spikelet is that of *Agropyrum.*

3. **A. scabrum** *Beauv. Agrost.* (1812) 102.—Annual or perennial, very variable. Culms laxly tufted, slender, decumbent at the base, erect or ascending above, quite smooth, leafy, 6–24 in. high. Leaves 2–9 in. long, $\frac{1}{20}$–$\frac{1}{10}$ in. broad, flat or convolute, usually scabrid on both surfaces, often glaucous; sheaths smooth, grooved, the upper long; ligules short, truncate. Spike 3–9 in. long, of 2–10 rather distant erect spikelets; rhachis flattened, scabrid on the angles. Spikelets ¾–1 in. long without the awns, 1½–3 in. with them, 6–12-flowered. Two outer glumes small, not reaching more than ⅓ up the flowering glumes immediately above them, subequal, narrow-lanceolate, tapering into short acuminate points, rigid, 3–5-nerved. Flowering glumes lanceolate, coriaceous, smooth and rounded on the back at the base, obscurely keeled and scabrid above, 3–5-nerved, narrowed into a long and slender straight or flexuous scabrid awn from 3 to 5 times as long as the glume itself. Palea almost as long as the glume, linear-oblong, ciliolate on the keels.—*Benth. Fl. Austral.* vii (1878) 665; *Cheesem. Man. N.Z. Fl.* (1906) 923. Triticum scabrum *R. Br. Prodr.* (1810) 178; *A. Rich. Fl. Nouv. Zel.* (1832) 137; *A. Cunn. Precur.* (1836) n. 260; *Raoul Choix* (1846) 39; *Hook. f. Fl. Nov. Zel.* i (1853) 311; *Handb. N.Z. Fl.* (1864) 342; *Buch. N.Z. Grasses* (1880) t. 57. Festuca scabra *Labill. Pl. Nov. Holl.* i (1806) 22, t. 26. Triticum Youngii *Hook. f. Handb. N.Z. Fl.* (1864) 343. Agropyrum Youngii *Cheesem. Man. N.Z. Fl.* (1906) 923.

KERMADEC ISLANDS, NORTH AND SOUTH ISLANDS, STEWART ISLAND: Abundant throughout. Sea-level to 4500 ft.

Also plentiful in Australia, from Queensland to Tasmania and West Australia. In small specimens the spike is sometimes reduced to a single terminal spikelet. Subalpine specimens usually have larger and fewer spikelets with longer awns than those from lowland districts, but the size of the spikelet and length of the awns varies excessively. I have reduced Hooker's *Triticum Youngii* to *A. scabrum*. So far as I can judge from the original description (for it has not been collected since it was discovered by Haast in 1861), it only differs from *A. scabrum* in the larger size of the spikelets and the longer and stouter awns, and, considering how variable these characters are in *A. scabrum*, I can have little doubt in transferring it to that species.

COCKAYNEA 2010. Trans 13 233
HYSTRIX Moench Meth. Pl. 294 (1794)

33. **ASPERELLA** Humb. 1790

Perennial grasses. Leaves narrow, flat. Spikelets 1- to several-flowered, 2–3 together or solitary in the alternate hollows of the rhachis of a simple slender spike, one face of the spikelet next the rhachis; rhachilla disarticulating above the two outer glumes and between the flowering glumes. Two outer glumes either wanting, or present in the lower spikelets as minute subulate bristles. Flowering glumes narrow-lanceolate, rigid, convolute, rounded on the back, 5-nerved above, produced into a short awn. Palea rather shorter than the glume, 2-keeled. Lodicules 2, obovate or dimidiate-obovate, hairy. Stamens 3. Styles short, distinct; stigmas plumose. Grain narrow-oblong, villous at the tip, grooved down the front, adherent to the palea.

A small genus of 7 species—2 in New Zealand, 2 in North America, and 1 each in the Himalayas, Japan, and Siberia.

Outer glumes often wanting. Flowering glumes more or less scabrid, distinctly 5-nerved, narrowed into an awn of varying length .. 1. *A. gracilis.*

Outer glumes always present. Flowering glumes smooth, faintly 3–5-nerved, truncately 3-toothed at the apex, the middle tooth produced into a short mucro .. .. 2. *A. laevis.*

C. (Hooker) 2

1. **A. gracilis** (*T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 352.—Perennial. Culms much branched and decumbent at the base, erect above, slender, often rather wiry, quite smooth and glabrous, leafy throughout, 1–3 ft. high. Leaves 3–9 in. long, $\frac{1}{12}$–$\frac{1}{6}$ in. broad, flat, striate, minutely scabrid on the margins and upper surface; sheaths smooth, thin, striate; ligules often obscure. Spike elongated, 3–8 in. long, very slender, of 20–40 sessile spikelets placed singly in the alternate hollows of the rhachis; rhachis compressed, flat, flexuous, ciliate on the edges. Spikelets pale-green, $\frac{1}{3}$–$\frac{2}{3}$ in. long with the awns, 1–3-flowered. Two outer glumes altogether absent or reduced to minute bristles. Flowering glumes lax, lanceolate, 5-nerved, rounded on the back below, midrib prominent above, usually more or less scabrid but sometimes nearly smooth, gradually narrowed into a scabrid awn of variable length, callus prominent. Palea almost as long as the glume, keels ciliate.—*Cheesem. Man. N.Z. Fl.* (1906) 924. Gymnostichum gracile *Hook. f. Fl. Nov. Zel.* i (1853) 312, t. 70; *Handb. N.Z. Fl.* (1864) 343; *Buch. N.Z. Grasses* (1880) t. 58.

NORTH AND SOUTH ISLANDS: Auckland—Kaitaia, *H. B. Matthews!* Te Pahi, Kaipara, *T. Kirk!* Thames, *Adams! T. F. C.*; Te Aroha, *Adams!* Rotorua, *T. F. C.*; East Cape district, *Adams* and *Petrie*. Hawke's Bay—Tarawera, Dannevirke, *Colenso!* Turangarere, *Petrie*. Wellington—*Buchanan*. Nelson—Lower Motueka, Graham River, *T. F. C.* Canterbury—Akaroa, *Raoul, J. B. Armstrong*; Mount Peel, *H. H. Allan*; Mount Cook district, *T. F. C.* Otago—Not uncommon in lowland districts, *Buchanan! Petrie!* Sea-level to 3000 ft. see Petrie Trans 13 : 332

2. **A. laevis** (*Petrie*) *in Trans. N.Z. Inst.* xxvii (1895) 406.—Culms branched from the base, slender, erect or diffuse, sparingly leafy, 10–30 in. high. Leaves 3–9 in. long, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, flat or involute, striate, smooth or nearly so; sheaths smooth or puberulous; ligules short. Spike 3–6 in. long, slender, of 15–30 spikelets; rhachis flat, flexuous, scabrid on the edges. Spikelets pale-green, about $\frac{1}{3}$ in. long, 1-2-flowered. Two outer glumes always present, reduced to linear-subulate bristles about $\frac{3}{4}$ the length of the lower flowering glume, subequal, erect, channelled, scabrid. Flowering glumes lanceolate, faintly 3–5-nerved, rounded on the back, quite smooth, unequally 3-toothed at the apex, the middle tooth produced into a short scabrid mucro. Palea rather shorter than the glume, keels smooth or minutely ciliolate.—*Cheesem. Man N.Z. Fl.* (1906) 924.

SOUTH ISLAND: Nelson—Clarence Valley, *T. Kirk!* Otago—Matukituki Valley, Catlin's River, *Petrie!* Waikawa, *H. J. Matthews!* Doubtful Sound, *B. C. Aston!* Sea-level to 2000 ft.

Very close to *A. gracilis*, from which it differs in the two outer glumes being always present, and in the flowering glumes being smooth, obscurely nerved, and truncately 3-toothed at the apex, the middle tooth being produced into a short stout mucro. Further observation is required to prove the constancy of these characters.

Family XII. CYPERACEAE.

Grassy or rush-like herbs, usually perennial. Stems solid or rarely slightly hollow, often trigonous, sometimes compressed or terete. Leaves alternate, mostly radical, few or many, sometimes wanting or reduced to sheathing scales; sheaths closed, not split to the base. Flowers hermaphrodite or unisexual, minute, solitary and sessile in the axils of small imbricated bracts (glumes), which are aggregated into few- or many-flowered (rarely 1-flowered) spikelets. Spikelets either solitary and terminal, or arranged in spikes, racemes, panicles, or clusters. Glumes rigid or scarious or membranous, concave, distichous or imbricated all round, persistent or deciduous, 1 or 2 (rarely more) at the base of each spikelet empty. Perianth wanting or represented by few hypogynous bristles or scales. Stamens 1–3, rarely 4–6, hypogynous; filaments linear, flat, often elongating after flowering; anthers usually exserted from the spikelet and pendulous, linear, basifixed, 2-celled. Ovary entire, 1-celled, in *Carex* and its allies enclosed in a peculiar flask-shaped organ called the utricle or perigynium formed of 1 or 2 modified bracteoles; style short or long, 2–3-cleft, divisions stigmatic on the inner side; ovule solitary, basal, erect, anatropous. Fruit a small indehiscent nut (in *Carex* enclosed in the utricle), lenticular or compressed or more often trigonous. Seed erect; testa membranous; albumen farinaceous; embryo minute, at the very base of the albumen.

A very large family, found in all parts of the world, both temperate and tropical, and in almost all stations, but most abundant in marshes, or by the margins of lakes and rivers. It is closely allied to grasses, being chiefly distinguished by the stiffer habit, solid and usually angled or compressed stems, entire leaf-sheaths, basifixed anthers, undivided (not plumose) stigmas, and by the position of the embryo. Genera 68; species estimated at 3500. Notwithstanding the extent of the order, it is of little economic importance. The herbage is too coarse and harsh, and too deficient in nutritive properties, to be serviceable as food for cattle; and the seed is useless. The tuberous roots of certain species of *Scirpus* and *Cyperus* contain starch, and have been used as food, while in others they are bitter, tonic, and stimulating, and have been employed in medicine. Many species are serviceable for paper-making, or in the

    Stems leafy at base, lower bract not glume-like . . . . . scirpus

RHACHILLA ?

SCIRPUS

used as food, while in others they are bitter, tonic, and stimulating, and have been employed in medicine. Many species are serviceable for paper-making, or in the

fabrication of mats, baskets, &c. The paper of the ancients was manufactured from the well-known *Papyrus*, a plant common along the Nile and in other parts of tropical Africa. Of the 14 genera found in New Zealand 9 are either cosmopolitan or very widely distributed; 2 (*Carpha* and *Oreobolus*) are confined to Australia and South America; *Uncinia* has a similar range, but extends northwards to the Sandwich Islands, Mexico, and the West Indies; the 2 remaining (*Lepidosperma* and *Gahnia*) are mainly Australian, but reach as far north as Malaya and China.

In the first edition of this work I received great assistance from the late Mr. C. B. Clarke, who had an unrivalled knowledge of the family. He not only supplied me with full information and critical notes respecting the New Zealand species, but also provided me with a list of the synonymy of the species, which proved to be of the greatest possible use, and which I have again consulted, with much profit, during the present rearrangement. I have also to acknowledge the great help derived from Pastor Kukenthal's recent revision of the genera *Uncinia* and *Carex*, given in Heft 30 of Engler's Pflanzenreich.

Tribe CYPEREAE.—Spikelets usually many-flowered, flat or compressed. Glumes distichous, imbricate, lower 1–2 empty. Flowers hermaphrodite or the upper 1–2 male by arrest. Hypogynous bristles absent.

Spikelets small, 1- or rarely 2-flowered, clustered in a simple or lobed head. Style 2-fid .. .. 1. KYLLINGA.
Spikelets many-flowered; glumes falling away from the persistent rhachilla. Style 3-fid .. .. 2. CYPERUS.
Spikelets many-flowered; glumes persistent, the rhachilla finally coming away above the 2 lowest. Style 3-fid .. .. 3. MARISCUS.

Tribe SCIRPEAE.—Spikelets usually many-flowered, terete. Glumes spirally arranged, lower 1–2 empty. Flowers hermaphrodite or the upper 1–2 male. Hypogynous bristles often present.

Leafless. Spikelet solitary, terminal. Nut crowned by the persistent thickened base of the style. Hypogynous bristles present .. .. 4. ELEOCHARIS.
Leaves radical. Spikelets umbellate. Style bulbous at the base, usually deciduous. Hypogynous bristles wanting .. .. 5. FIMBRISTYLIS.
Spikelets few or many, fascicled or umbelled. Style not thickened at the base, continuous with the nut. Hypogynous bristles present or wanting .. .. 6. SCIRPUS.

Tribe RHYNCHOSPOREAE.—Spikelets 1- or few-flowered, terete or compressed. Glumes spirally arranged, several (usually more than 2) of the lower ones empty. Hermaphrodite flowers 1 or 2; the remainder male or imperfect.

Alpine, leafy at the base. Spikelets in a terminal corymb, compressed, pale, 1-flowered; glumes 4, distichous. Hypogynous bristles long, plumose .. .. 7. CARPHA.
Spikelets few-flowered, compressed; glumes several, distichous. Rhachilla often elongated and flexuose between the flowers .. 8. SCHOENUS.
Spikelets 1–7-flowered, lowest flower alone hermaphrodite; glumes not distichous. Stamens 3, rarely elongating. Hypogynous bristles wanting.. .. .. 9. CLADIUM.
Spikelets 1–3-flowered, upper flower alone hermaphrodite. Stamens 3, rarely elongating. Hypogynous bristles present .. 10. LEPIDOSPERMA.
Tall, harsh and grassy. Spikelets 1–3-flowered, upper flower alone hermaphrodite. Stamens 3–6, usually elongating in fruit and holding the nut. Hypogynous bristles wanting .. 11. GAHNIA.
Dwarf alpine plants forming dense cushions in bogs. Spikelets solitary or 2–3 together, 1-flowered; glumes 3. Hypogynous scales (perianth) 6, persistent .. .. 12. OREOBOLUS.

Tribe CARICEAE.—Spikelets monoecious, the male and female flowers in the same or in distinct spikelets; rarely dioecious. Nuts enclosed in an entire or 2-fid inflated sac (utricle).

Spikelet solitary, androgynous. Rhachilla produced beyond the utricle into a hooked bristle .. .. 13. UNCINIA.
Spikelet solitary, or more often clustered or spicate or panicled, androgynous or unisexual. Rhachilla not produced beyond the utricle .. .. 14. CAREX.

1. KYLLINGA Rottb. 1773.

Stems slender, simple, erect, leafy at the base. Spikelets small, numerous, compressed, 1–3-flowered, densely crowded in 1–3 ovoid or cylindric terminal heads or spikes subtended by 2–6 unequal linear leaf-like bracts. Glumes 4–7, distichous; the two lowest small, empty; the next, or rarely the two next, hermaphrodite and fruit-bearing; the upper ones male or the uppermost smaller and empty; in fruit the rhachilla falls away above the two lowest glumes. Hypogynous scales wanting. Stamens 1–3. Style continuous with the ovary, not thickened at the base; branches 2, filiform. Nut laterally compressed, smooth.

A genus of about 50 species, widely spread through the warmer regions of both hemispheres, but not found in Europe.

1. **K. brevifolia** *Rottb. Desc. et Ic.* (1773) t. 4, f. 3.—Rhizome creeping, elongate. Stems numerous from the rhizome, slender, 4–12 in. high or more. Leaves flat, grassy, usually shorter than the stems, $\frac{1}{10}$–$\frac{1}{6}$ in. broad. Bracts usually 3, spreading, similar to the leaves. Spikes solitary or rarely 2–3 together, broadly ovoid, greenish, $\frac{1}{5}$–$\frac{1}{3}$ in. long. Spikelets about $\frac{1}{8}$ in.; fertile flower usually solitary. Glume of fertile flower ovate, mucronate, eglandular, keeled; keel not winged above, 3-nerved; sides of glume with 3–4 striae. Stamens 2. Nut ellipsoid, pale yellow-brown, about $\frac{1}{2}$ as long as the glume.—*C. B. Clarke in Hook. f. Fl. Brit. Ind.* vi (1893) 588; *Ill. Cyp.* t. i, f. 1–4; *Cheesem. Man. N.Z. Fl.* (1906) 764. K. monocephala *Cheesem. in Trans. N.Z. Inst.* xi (1879) 434 (*not of Rottb.*).

Common in most warm countries, and possibly only naturalized in New Zealand. It is very closely allied to the equally abundant *K. monocephala*, to which I formerly referred it, but which can be distinguished by the glume of the fertile flower having the upper part of the keel winged or crested and more or less glandular.

Kermadec Islands: *W. R. B. Oliver!* North Island: From Ahipara and Mangonui northwards to the North Cape, *W. T. Ball! T. F. C., H. Carse!* Also naturalized near the North Manukau Head.

2. CYPERUS Linn. 1735.

Annual or more commonly perennial herbs. Stems erect, simple below the inflorescence. Leaves at the base of the stem, usually long, the lowest sometimes reduced to sheaths. Inflorescence umbellate or capitate, often large and compound; bracts at the base long, leaf-like, spreading. Spikelets oblong or linear, compressed; rhachilla persistent. Glumes usually many, distichous; the two lowest empty; four at least and generally many of the succeeding ones hermaphrodite and fruit-bearing, falling away from the rhachilla one by one, commencing with the lowest; the uppermost 1–3 sterile or empty. Stamens 2–3, rarely 1. Style continuous with the ovary, not thickened at the base; branches 3, filiform. Nut triquetrous or plano-convex, the flat face against the rhachilla, surface smooth.

A large genus of over 375 species, most abundant in the tropical and subtropical districts of both hemispheres, comparatively rare in temperate regions. The two New Zealand species are widely distributed; one of them is certainly a recent introduction, and possibly the other as well.

Small, 1–3 in. high. Inflorescence of a single head; spikelets 1–3 . . . . . 1. *C. tenellus.*
Tall, 1–2 ft. high. Inflorescence in a compound umbel; spikelets very numerous . . . . . 2. *C. vegetus.*

The tropical *C. rotundus* Linn., easily recognized by the black ovoid tubers on the creeping stolons, and hence frequently known by the name of "nut-grass," has become naturalized in the vicinity of Auckland. It is a most pernicious weed.

C. tenellus L. var australiensis B.H. Brown. "New Polynesian Plants" Bish. Mus. occ. papers IX, 4, 1930: p 7.

1. **C. tenellus** *Linn. f. Suppl.* (1781) 103.—A small densely tufted annual. Stems numerous, very slender, almost filiform, 1–3 in. high. Leaves few, much shorter than the stem, filiform. Spikelets 1–3 together, digitate, much flattened, oblong, obtuse, large for the size of the plant, $\frac{1}{8}$–$\frac{1}{4}$ in. long; bracts 2, setaceous, one erect and continuous with the stem, the other much smaller. Glumes 10–25, regularly distichous, ovate, obtuse or mucronate, boat-shaped, conspicuously 5–9-nerved, varying in colour from almost white to red-brown. Stamens 1 or 2. Style-branches 3, linear. Nut rather more than $\frac{1}{2}$ the length of the glume, elliptical, acutely trigonous, smooth.—*Hook. f. Handb. N.Z. Fl.* (1864) 745; *Benth. Fl. Austral.* vii (1878) 265; *C. B. Clarke in Fl. Cap.* vii (1897) 164; *Cheesem. Man. N.Z. Fl.* (1906) 765.

See Kirk 1942. 42: 77. H. O'Neill.

3. **MARISCUS** Gaertn.

Stems erect, simple below the inflorescence, leafy at the base. Inflorescence of the same forms as in *Cyperus*. Spikelets oblong or linear, compressed; rhachilla disarticulating above the two lowest empty glumes, and falling away in one piece, leaving a terminal rounded boss or knob. All other characters as in *Cyperus*.

Species about 180, found in all tropical and subtropical regions, but not extending into Europe. The single New Zealand species is endemic.

(A. Rich.)

1. **M. ustulatus**, *C. B. Clarke MS.*—Very robust, 2–4 ft. high. Stem smooth, striate, trigonous, $\frac{1}{4}$ in. diam. Leaves crowded at the base of the stem, long, keeled, coriaceous, spongy towards the base, $\frac{1}{3}$–1 in. broad;

North Island: From the North Cape southwards to Taranaki and Hawke's Bay, abundant. Sea-level to 1500 ft. November–December.

A common South African plant, doubtfully indigenous in temperate Australia and New Zealand.

2. **C. vegetus** *Willd. Sp. Plant.* i (1797) 283.—Roots fibrous. Stems 1–2 ft. high, rather stout, smooth, sharply 3-angled above. Leaves shorter than the stem, rather flaccid, $\frac{1}{6}$–$\frac{1}{3}$ in. broad; margins smooth. Inflorescence a terminal compound umbel varying from $1\frac{1}{2}$ to 6 in. diam.; rays 5–9, unequal, each terminated by a dense globose umbellule; bracts about 6, similar to the leaves, long and spreading, the lowest in large specimens sometimes 18 in. long. Spikelets very numerous, pale yellowish-green, much compressed, $\frac{1}{3}$–$\frac{3}{4}$ in. long, 12–40-flowered. Glumes distichous, boat-shaped, ovate, apiculate, 3-nerved, margins membranous. Stamen 1. Nut about $\frac{2}{3}$ the length of the glume, obovoid-triquetrous, shortly rostrate. Style-branches 3, linear.—*Cheesem. Man. N.Z. Fl.* (1906) 766. *C. gracilis Buch. in Trans. N.Z. Inst.* iii (1871) 210 (*not of R. Br.*). C. Buchanani *T. Kirk in Trans. N.Z. Inst.* x (1878) App. xli.

North Island: Auckland—Oruru and Oruaiti Valleys, near Mangonui, *T. F. C.* Wellington—Lower Hutt, Waiwetu, Wainuiomata, Greytown, *Buchanan! T. Kirk!* Tararua Mountains, Cape Turakirae, *B. C. Aston!* November–January.

The true home of this plant, as has been pointed out by Mr. C. B. Clarke (Journ. Bot. 1897, 71) is in temperate South America, and there can be no doubt that it exists only as an introduced species in New Zealand, as also in many localities in southern Europe, the Azores, North America, Tahiti, &c. I retain it in the Flora because it has been twice described as an indigenous species, and on account of the remarkable fact that wherever found it presents all the appearance of a true native, and would certainly be taken as such by any one unacquainted with its origin.

See Rhodora 1942. 44: 77. A. O'Neill.

3. **MARISCUS** Gaertn. 1788

Stems erect, simple below the inflorescence, leafy at the base. Inflorescence of the same forms as in *Cyperus*. Spikelets oblong or linear, compressed; rhachilla disarticulating above the two lowest empty glumes, and falling away in one piece, leaving a terminal rounded boss or knob. All other characters as in *Cyperus*.

Species about 180, found in all tropical and subtropical regions, but not extending into Europe. The single New Zealand species is endemic.

(B. Rock)

1. **M. ustulatus** *C. B. Clarke MS.*—Very robust, 2–4 ft. high. Stem smooth, striate, trigonous, $\frac{1}{4}$ in. diam. Leaves crowded at the base of the stem, long, keeled, coriaceous, spongy towards the base, $\frac{1}{3}$–1 in. broad;

margins and keel sharply and minutely serrulate. Inflorescence a large terminal umbel often more than 6 in. diam.; rays 6–10, each bearing an oblong spike 1–2 in. long of very numerous red-brown spikelets; bracts numerous, forming an involucre at the base of the umbel, very long and leafy, the lowest frequently over 2 ft. Spikelets linear-lanceolate, $\frac{1}{3}$–1 in. long, 5–20-flowered. Glumes distichous, ovate-oblong, obtuse or mucronate, smooth and shining, grooved. Stamens 3. Nut linear-oblong, trigonous; style-branches 3.—*Cheesem. Man. N.Z. Fl.* (1906) 766. Cyperus ustulatus *A. Rich. Fl. Nouv. Zel.* (1832) 101, t. 17; *A. Cunn. Precur.* (1836) n. 270; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 268; *Handb. N.Z. Fl.* (1864) 297.

forma grandispiculosa, Kükenth. ex Carse.

Kermadec Islands: Plentiful, *T. F. C., W. R. B. Oliver!* North Island: Abundant in lowland districts at low levels throughout. South Island: Chiefly near the coast, extending as far south as Okarito (*Hamilton*) and northern Otago (*Buchanan*). Stewart Island: Half-moon Bay, *Miss Chase!* Sea-level to 1500 ft. *Toetoe-upoko-tangata; Toetoe-whatu-manu.* November–January.

See H. K. Svenson Monographic studies (H.) in genus Eleocharis Rhodora 31: 1929

4. ELEOCHARIS R. Br. 1810.

Stems simple, erect, without perfect leaves. Sheaths few, the uppermost cylindric, truncate or produced on one side into a short tooth. Inflorescence a single terminal many-flowered terete spikelet. Glumes many, imbricate all round the rhachis; the lowest 1 or 2 empty, shorter than the spikelet; many succeeding ones hermaphrodite and fruit-bearing; the uppermost male or sterile. Hypogynous bristles usually 6, but varying from 3 to 8, rarely absent. Stamens 3 or fewer. Style swollen at the base; branches 3 or 2, linear. Nut obovoid, trigonous or plano-convex.

Species estimated at 100, distributed over the whole world, but most numerous in America. Of the 5 found in New Zealand, 2 are endemic, 2 extend to Australia, the remaining one is almost cosmopolitan.

A. Limnochloa. *Stem stout, spikelet large, hardly wider than the stem. Glumes subrigid.*

Stems stout, septate. Spikelet 1–2 in. long .. .. .. 1. *E. sphacelata.*

B. Eleogenus. *Stem slender. Spikelets small, broader than the stem. Glumes membranous. Style 2-fid.*

Stems short, 1–2$\frac{1}{2}$ in. Spikelet $\frac{1}{6}$–$\frac{1}{4}$ in. .. .. .. 2. *E. neo-zealandica.*

1. **E. sphacelata** *R. Br. Prodr.* (1810) 224.—Rhizome stout, creeping, stoloniferous. Stems stout, cylindrical, 1–3 ft. high, $\frac{1}{3}$ in. diam., hollow, transversely septate; sheaths long, membranous. Spikelet very large, 1–2 in. long, $\frac{1}{3}$ in. diam., solitary, terminal, cylindrical, pale-coloured, tip acute. Glumes numerous, very closely imbricate, obovate-oblong, obtuse, 1-nerved, membranous, pale with a brown line just inside the scarious margin. Hypogynous bristles 6–9, usually exceeding the nut, retrorsely scabrid. Style very long, branches 3. Nut broadly obovoid, compressed,

minutely granular, pale, crowned with the persistent dark-brown conic swollen base of the style.—*A. Cunn. Precur.* (1836) n. 277; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 269; *Handb. N.Z. Fl.* (1864) 300; *Benth. Fl. Austral.* vii (1878) 292 (Heleocharis); *Cheesem. Man. N.Z. Fl.* (1906) 767; *C. B. Clarke Ill. Cyp.* (1909) t. xxxiv, f. 1–6.

North Island: Wet swamps and margins of lakes, not uncommon at low altitudes. South Island: Nelson—Takaka, *T. Kirk!* Canterbury—*J. B. Armstrong.* Westland—Okarito, *A. Hamilton!* Southland—Bluff Island, *Lyall.* Stewart Island: Head of Paterson's Inlet, *Petrie!* swamps from Fresh-water Valley to Mason Bay, *Cockayne.* Sea-level to 1500 ft. December–February.

An abundant Australian and Tasmanian plant, and very closely allied to the widely diffused *E. plantaginea* R. Br.

2. **E. neo-zealandica** *C. B. Clarke ex T. Kirk in Trans. N.Z. Inst.* xxxi (1894) 260.—Rhizome slender, creeping, 1–3 in. long. Stems short, 1–2½ in. high, striate; sheath membranous, mouth oblique. Spikelet solitary, terminal, ⅙–¼ in. long, broadly ovoid, much wider than the stem, 4–8-flowered. Glumes broadly ovate, concave, obtuse, red-brown with a paler centre and scarious margins. Hypogynous bristles wanting. Stamens 3. Style with 2 linear arms and a very small swollen base. Nut obovoid, biconvex, smooth, pale-brown.—*Cheesem. Man. N.Z. Fl.* (1906) 768; *C. B. Clarke Ill. Cyp.* (1909) t. xxxvi, f. 10–14.

North Island: Auckland—Sand-dunes between Cape Maria van Diemen and Ahipara, *T. F. C., H. Carse!* South Island: Nelson—Cape Farewell, *T. Kirk!*

A curious little species, belonging to the section *Eleogenus*, characterized by the spikelets broader than the slender stems, membranous glumes, and 2-fid style. Mr. Clarke remarks that it approaches the section *Isolepis* of *Scirpus* in the absence of hypogynous bristles and the reduced

margins and keel sharply and minutely serrulate. Inflorescence a large terminal umbel often more than 6 in. diam.; rays 6–10, each bearing an oblong spike 1–2 in. long of very numerous red-brown spikelets; bracts numerous, forming an involucre at the base of the umbel, very long and leafy, the lowest frequently over 2 ft. Spikelets linear-lanceolate, $\frac{1}{3}$–1 in. long, 5–20-flowered. Glumes distichous, ovate-oblong, obtuse or mucronate, smooth and shining, grooved. Stamens 3. Nut linear-oblong, trigonous; style-branches 3.—*Cheesem. Man. N.Z. Fl.* (1906) 766. Cyperus ustulatus *A. Rich. Fl. Nouv. Zel.* (1832) 101, t. 17; *A. Cunn. Precur.* (1836) n. 270; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 268; *Handb. N.Z. Fl.* (1864) 297.

forma grandispiculosa, Kükenth. ex Cheesem.

Kermadec Islands: Plentiful, *T. F. C., W. R. B. Oliver!* North Island: Abundant in lowland districts at low levels throughout. South Island: Chiefly near the coast, extending as far south as Okarito (*Hamilton*) and northern Otago (*Buchanan*). Stewart Island: Half-moon Bay, *Miss Chase!* Sea-level to 1500 ft. *Toetoe-upoko-tangata; Toetoe-whatu-manu.* November–January.

See H.K. Svenson (H.) Monographic studies in genus Eleocharis: Rhodora 31: 1929

4. **ELEOCHARIS** R. Br. 1810.

Stems simple, erect, without perfect leaves. Sheaths few, the uppermost cylindric, truncate or produced on one side into a short tooth. Inflorescence a single terminal many-flowered terete spikelet. Glumes many, imbricate all round the rhachis; the lowest 1 or 2 empty, shorter than the spikelet; many succeeding ones hermaphrodite and fruit-bearing; the uppermost male or sterile. Hypogynous bristles usually 6, but varying from 3 to 8, rarely absent. Stamens 3 or fewer. Style swollen at the base; branches 3 or 2, linear. Nut obovoid, trigonous or plano-convex.

minutely granular, pale, crowned with the persistent dark-brown conic swollen base of the style.—*A. Cunn. Precur.* (1836) n. 277; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 269; *Handb. N.Z. Fl.* (1864) 300; *Benth. Fl. Austral.* vii (1878) 292 (Heleocharis); *Cheesem. Man. N.Z. Fl.* (1906) 767; *C. B. Clarke Ill. Cyp.* (1909) t. xxxiv, f. 1–6.

North Island: Wet swamps and margins of lakes, not uncommon at low altitudes. South Island: Nelson—Takaka, *T. Kirk!* Canterbury—*J. B. Armstrong.* Westland—Okarito, *A. Hamilton!* Southland—Bluff Island, *Lyall.* Stewart Island: Head of Paterson's Inlet, *Petrie!* swamps from Fresh-water Valley to Mason Bay, *Cockayne.* Sea-level to 1500 ft. December–February.

An abundant Australian and Tasmanian plant, and very closely allied to the widely diffused *E. plantaginea* R. Br.

2. **E. neo-zealandica** *C. B. Clarke ex T. Kirk in Trans. N.Z. Inst.* xxxi (1894) 260.—Rhizome slender, creeping, 1–3 in. long. Stems short, 1–2½ in. high, striate; sheath membranous, mouth oblique. Spikelet solitary, terminal, ⅙–¼ in. long, broadly ovoid, much wider than the stem, 4–8-flowered. Glumes broadly ovate, concave, obtuse, red-brown with a paler centre and scarious margins. Hypogynous bristles wanting. Stamens 3. Style with 2 linear arms and a very small swollen base. Nut obovoid, biconvex, smooth, pale-brown.—*Cheesem. Man. N.Z. Fl.* (1906) 768; *C. B. Clarke Ill. Cyp.* (1909) t. xxxvi, f. 10–14.

North Island: Auckland—Sand-dunes between Cape Maria van Diemen and Ahipara, *T. F. C., H. Carse!* South Island: Nelson—Cape Farewell, *T. Kirk!*

A curious little species, belonging to the section *Eleogenus*, characterized by the spikelets broader than the slender stems, membranous glumes, and 2-fid style. Mr. Clarke remarks that it approaches the section *Isolepis* of *Scirpus* in the absence of hypogynous bristles and the reduced size of the swollen base of the style.

3. **E. acicularis** *R. Br. Prodr.* (1810) 224.—Rhizome very slender, almost filiform, creeping, stoloniferous. Stems numerous, tufted, extremely slender, capillary, 2–6 in. high; sheaths membranous, acute. Spikelet small, slender, ⅛–⅕ in. long, compressed, pale to dark-brown, 3–6-flowered. Glumes ovate, obtuse, membranous, brown with a greenish or pale centre and narrow scarious margins. Hypogynous bristles 2–4, short, deciduous. Style-branches 3; style-base small, conic, depressed. Nut small, pale, obovoid-oblong, longitudinally ribbed and with minute transverse striae between the ribs.—*Kunth Enum.* ii (1833) 141; *C. B. Clarke in Hook. f. Fl. Brit. Ind.* vi (1893) 628.

South Island: Otago—Lake Te Anau, *Petrie!* (No. 1647).

I have seen no specimens but Mr. Petrie's, which are in young flower only. Mr. C. B. Clarke, who has examined them, states that he is satisfied that they belong to the small group consisting of *E. acicularis* and a very few closely allied species, and most probably to *E. acicularis* itself, which is an almost cosmopolitan plant, although not yet recorded from Australia.

4. **E. acuta** *R. Br. Prodr.* (1810) 224.—Rhizome creeping. Stems numerous, tufted, 4–18 in. high, rather stout or slender, striate; sheath closely appressed to the stem, with a horizontally truncate mouth, the margin of which is thickened and usually dark-coloured, with a small erect mucro or rudimentary lamina on one side. Spikelet variable in length, ¼–¾ in. or more, linear-oblong, cylindric, obtuse or subacute, many-flowered. Glumes broadly ovate, obtuse, membranous, concave, brown with usually a pale line down the centre; margins broad, scarious. Hypogynous scales

4–8, exceeding the nut. Stamens 3. Style-branches 3. Nut broadly obovoid, biconvex, smooth or very minutely pitted, brown, crowned by the small conic style-base.—*Hook. f. Handb. N.Z. Fl.* (1864) 745; *Benth. Fl. Austral.* vii (1878) 294 (Heleocharis); *Cheesem. Man. N.Z. Fl.* (1906) 768. E. gracilis (*excl. var.* b *and* y) *Hook. f. Fl. Nov. Zel.* i (1853) 270; *Handb. N.Z. Fl.* (1864) 301. E. ambigua *T. Kirk ex Buch. in Trans. N.Z. Inst.* vi (1874) 225.

Kermadec Islands: *W. R. B. Oliver!* North and South Islands, Chatham Islands: Abundant in wet places from the North Cape to Foveaux Strait. Stewart Island: *Cockayne.* Sea-level to 3500 ft. November–March.

Also plentiful in Australia, Tasmania, and Norfolk Island.

5. **E. Cunninghamii** *Boeck. in Flora*, xli (1858) 412 (Heleocharis).—Rhizome long, creeping, scaly, stout or slender, dark red-brown or almost black. Stems many from the rhizome, variable in length, 3–15 in., very slender, sometimes almost filiform, striate; sheath membranous, with a thin oblique mouth. Spikelet small, short, $\frac{1}{8}$–$\frac{1}{4}$ in. long, broadly ovoid, subacute, 5–20-flowered. Glumes broadly oblong, obtuse, membranous, usually pale but often stained with red-brown; margins broad, scarious. Hypogynous bristles 4–8, exceeding the nut. Style-branches 3. Nut broadly obovoid, plano-convex or obscurely trigonous, smooth, pale yellowish-brown, crowned by the small pyramidal style-base, which is rather broader than the top of the nut.—*Linnaea*, xxxvi (1869–70) 427; *Cheesem. Man. N.Z. Fl.* (1906) 769. E. gracilis *var.* gracillima *and var.* radicans *Hook. f. Fl. Nov. Zel.* i (1853) 270; *Handb. N.Z. Fl.* (1864) 301 (*not of R. Br.*). E. gracillima *Hook. f. Handb. N.Z. Fl.* (1864) 745. Heleocharis Hookeri *Boeck. in Linnaea*, xxxvi (1869–70) 430. Isolepis acicularis *A. Rich. Fl. Nouv. Zel.* (1832) 103 (*not of R. Br.*).

North and South Islands.—Wet places from the North Cape to Foveaux Strait, but often local in the South Island. Stewart Island: Swampy ground, *Cockayne!* Sea-level to 4500 ft. November–March.

Hooker's two varieties *gracillima* and *radicans*, originally published as forms of the Australian *E. gracilis*, only differ in size and degree of development, *radicans* being clearly a depauperated state. In many localities they can be seen to merge into one another. Boeckeler, probably working upon scanty herbarium material, treated them as distinct species, publishing his *E. Cunninghamii*, which answers to var. *radicans*, in 1858, and *E. Hookeri*, which is equivalent to var. *gracillima*, in 1869. *E Cunninghamii* has several years' priority over Hooker's *gracillima*, which was not published until 1867, but it is unfortunate that it was not originally applied to what must be considered the type of the species, Hooker's var. *gracillima*.

5. **FIMBRISTYLIS** Vahl.

Annual or perennial tufted herbs, usually of small or medium size. Leaves from near the base of the stem, grassy or filiform. Inflorescence a terminal simple or compound umbel, or reduced to a solitary terminal spikelet. Spikelets many-flowered. Glumes imbricate all round or rarely distichous; the lowest 1–2 empty; the remainder all hermaphrodite, or the uppermost male or sterile. Hypogynous bristles wanting. Stamens 3, more rarely 2 or 1. Style often hairy or ciliate, with a bulbiform or conic base, deciduous; style-branches 3 or 2. Not obovoid, trigonous or biconvex, often narrowed at the base.

A large genus of about 140 species, found in all tropical or warm temperate regions.

1. **F. squarrosa** *Vahl. Enum.* ii (1806) 289.—A slender more or less pubescent annual 2–8 in. high; stems numerous, tufted, striate. Leaves linear, setaceous, shorter than the stems. Umbel terminal, usually compound, 1–3 in. diam.; rays slender, unequal, 1–2 in. long; bracts 3–4, similar to the leaves, often exceeding the umbel. Spikelets numerous, on slender pedicels, $\frac{1}{6}$–$\frac{1}{5}$ in. long, narrow-ovoid, brownish. Glumes elliptic-lanceolate, acuminate, keeled, 3-nerved, more or less squarrose. Stamens 1 or 2. Style pubescent, the bulbiform base with numerous long hairs which hang over the nut and are closely appressed to it; style-branches 2. Nut about $\frac{1}{3}$ the length of the glume, obovoid-oblong, biconvex, pale-yellow, smooth.

Var. **velata** *C. B. Clarke.*—Nerves of the glumes almost fused into a solid keel, the excurrent tip not nearly so squarrose.—F. velata *R. Br. Prodr.* (1810) 227; *Hook. f. Fl. Nov. Zel.* i (1853) 272; *Benth. Fl. Austral.* vii (1878) 309. F. dichotoma *Hook. f. Handb. N.Z. Fl.* (1864) 303 (*not of Vahl.*).

North Island: Auckland—Bay of Islands, *Colenso!* near Auckland (?), *Sinclair;* Port Waikato, *T. Kirk!* hot springs at Ohinemutu, Lake Rotorua, *T. Kirk! T. F. C.;* Lake Rotomahana, *Filhol.* Sea-level to 1000 ft. December-February.

The typical form of the species is found in most warm countries; the var. *velata* is restricted to eastern Australia and New Zealand.

6. **SCIRPUS** Linn. 1735

Glabrous annual or perennial herbs of very various habit, small and tufted, or tall and stout with a creeping rhizome. Leaves usually from near the base of the stem, long or short, sometimes reduced to appressed sheaths. Spikelets usually many-flowered, solitary or fascicled, or more numerous and umbellate or panicled. Glumes imbricate all round the rhachis; lowest 1 or 2 empty; several or many succeeding ones hermaphrodite and fruit-bearing; the uppermost sterile. Hypogynous bristles 3–8 or wanting. Stamens 3 or fewer. Style long or short, passing gradually into the nut; style-branches 2 or 3. Nut obovoid or broadly oblong, trigonous or plano-convex, sessile or nearly so.

A somewhat heterogeneous assemblage of about 145 species, found in all parts of the world, both tropical and temperate. Of the 13 species found in New Zealand, 4 are generally distributed in both the Northern and Southern Hemispheres; 6 extend to Australia, 3 of them reaching South Africa as well; 1 is found in Tristan d'Acunha; the remaining 2 are endemic. The student will find it a difficult and perplexing task to discriminate between several of the species of the first section.

Isolepis R. Br. Prodr. 221 1810

Section I. Isolepis. *Usually small and slender plants. Spikelets in clusters or solitary. Hypogynous bristles wanting.*

* Spikelets solitary or 2–3 in a head.

Stems long, slender, often much branched and floating. Spikelet solitary. Style-branches 2. Nut biconvex, white	1. *S. lenticularis.*
Stems very short, $\frac{1}{8}$–$\frac{1}{2}$ in. long, leafy. Spikelets usually solitary, concealed by the leaves. Style-branches 2. Nut biconvex, brown	2. *S. basilaris.*
Stems 1–6 in., branched below. Leaves several, equalling the stems. Spikelets 1–2. Style-branches 3. Nut obovoid, obtusely trigonous, white	3. *S. Aucklandicus.*
Stems 2–6 in. Leaves 1–2, shorter than the stems. Spikelets 1–3. Style-branches 3. Nut obovoid, obtusely trigonous	4. *S. cernuus.*

S. fluitans see Carse Trans 57:1926:89.
S. Carsei Kirk. et Carse.

** Spikelets usually more than 3 in a cluster (sometimes reduced to 1 in small states of *S. antarcticus* and *S. inundatus*).

Stems ½–6 in. Leaves 1–3, often rigid and cartilaginous. Spikelets 1–9; glumes rigid, keeled, grooved on the sides. Stamens 3. Style-branches 3. Nut acutely trigonous, yellow to dark-brown 5. *S. antarcticus.*

Stems 2–12 in., usually slender and flaccid. Leaves 1–2 or wanting. Heads often proliferous; spikelets 2–15. Stamen 1. Style-branches 3. Nut acutely trigonous, white .. .. .. 6. *S. inundatus.*

Stems 8–16 in., rather stout, leafless. Spikelets 6–20, short, oblong. Stamen usually 1. Style-branches 2. Nut plano-convex, smooth and polished, pale .. .. 7. *S. sulcatus.*

Stems 1–2 ft., rather stout, flaccid, leafless. Spikelets 10–30, long, linear. Stamens 3. Style-branches 3. Nut acutely trigonous.. 8. *S. prolifer.*

Stems 1–3 ft., stout, rigid, erect, leafless. Spikelets numerous, short, ovoid, crowded. Stamens 3. Style-branches 3. Nut obtusely trigonous, brown .. .. 9. *S. nodosus.*

Hk.f. Fl. N.Z. i 271 : 1853

Section II. Desmoschoenus. *Tall, harsh, rigid and coriaceous. Spikelets numerous, spirally arranged around the upper part of the stem. Hypogynous bristles wanting.*

Rhizome long. Stems 1-3 ft. Leaves numerous, subsquarrose .. 10. *S. frondosus.*

Section III. Eu-Scirpus. *Usually large. Stem leafy at the base or leaves wanting. Spikelets usually panicled or umbelled, rarely in heads or solitary. Hypogynous bristles present.*

Stems acutely trigonous, 1–2 ft. high. Leaves 1–4, trigonous, shorter than the stem. Spikelets few, crowded into a small head 11. *S. americanus.*

Stems terete, spongy, leafless, 2–6 ft. high. Spikelets in a broad panicle or umbel 2–4 in. diam. .. .. 12. *S. lacustris.*

Stems acutely trigonous, 1–5 ft. high. Leaves longer than the stems, broad, flat. Spikelets in a terminal umbel; involucral bracts long, leafy.. .. .. 13. *S. maritimus.*

S. lac.

1. **S. lenticularis** *Poir. Encyc. Suppl.* v (1817) 103.—Stems slender, in very wet places 6–18 in. long, elongated and much branched, putting out a small tuft of leaves at each node, often forming large floating masses; in drier situations shorter and stouter, much more sparingly branched, 2–6 in. high. Leaves 1–3 in. long, filiform in floating specimens, stouter in terrestrial ones. Peduncle shorter or longer than the leaves, slender, usually 1 from each tuft of leaves, each bearing a single terminal spikelet. Spikelets variable in size, ⅛–¼ in. long, oblong or oblong-ovoid, obtuse, pale-green; bract (lowest glume) usually longer than the spikelet. Glumes ovate, acute, concave but scarcely keeled, green, sometimes stained with chestnut-brown. Hypogynous bristles wanting. Stamens 2 or 3. Style-branches 2. Nut ¾ the length of the glume, obovoid, biconvex, tipped by a minute point, slightly narrowed at the base, smooth, pale.—*Benth. Fl. Austral.* vii (1878) 326; *Cheesem. Man. N.Z. Fl.* (1906) 772. S. fluitans *var.* terrestris *Benth. l.c.* 325. S. crassiusculus *Cheesem. in Trans. N.Z. Inst.* xv (1883) 300 (*not of Hook. f.*). Isolepis lenticularis *R. Br. Prodr.* (1810) 222; *Hook. f. Fl. Tasm.* ii (1860) 86, t. 145D. Isolepis fluitans *T. Kirk in Trans. N.Z. Inst.* iii (1871) 166 (*not of R. Br.*).

North Island: Auckland—North Cape Peninsula, *T. F. C.*; Lake Tongonge, *H. Carse!* Waikato River, Lakes Whangape, Waikare, and Waihi, *T. Kirk! T. F. C.*; Lake Taupo, *T. Kirk!* swamps near the base of Ruapehu, *Berggren! Tryon! A. Hamilton! Petrie!* Sea-level to 2500 ft. December–March.

Also in eastern Australia and Tasmania, and very closely allied to the widely spread *S. fluitans* L. In all probability two species are included in the present circumscription of the species, but my specimens are not sufficiently good to enable me to separate them in a satisfactory manner.

1. crassiusculus Hk f. see Trans 69:1939:277

2. **S. basilaris** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 772, *and Ill. Cyp.* (1909) t. xlvii, f. 3, 4.—A dwarf species forming dense tufts 1–3 in. diam. Stems very short, $\frac{1}{8}$–$\frac{1}{2}$ in. long, much branched at the base, leafy. Leaves far overtopping the stems, $\frac{1}{2}$–$1\frac{1}{2}$ in. long, sheathing at the base, semiterete above, channelled in front, convex at the back, tip obtuse. Spikelets terminal, solitary or rarely 2 together, concealed amongst the leaves and sometimes almost radical, $\frac{1}{10}$–$\frac{1}{6}$ in. long, ovoid, obtuse, pale-green; bract long, leafy. Glumes broadly ovate, obtuse, with broad white membranous margins, and a stout green midrib which is usually produced into a thick excurrent tip. Stamens 2. Style-branches 2. Nut orbicular-obovoid, not angled nor trigonous, slightly compressed, obtuse, smooth but not polished, minutely dotted, light- or dark-brown.—Isolepis basilaris *Hook. f. Handb. N.Z. Fl.* (1864) 302. I. novae-zealandiae *Col. in Trans. N.Z. Inst.* xxi (1889) 102.

North Island: Hawke's Bay — Mud-banks by the Ngaruroro River, *Colenso! T. Kirk! Petrie!* South Island: Westland—Jackson's, Teremakau River, *Petrie!* Otago—Not uncommon in the middle portion of the Clutha Valley, Roxburgh, Beaumont, Spear-grass Flat, *Petrie!* Pomahaka, *T. Kirk!* Sea-level to 2000 ft. November–March.

A curious little plant, in its usual state easily distinguished by the very short stems with the spikelets concealed by the leaves. But some forms have the stems more developed, and are then easily taken for small varieties of *S. Aucklandicus*, which, however, has a very different nut.

3. **S. Aucklandicus** *Boeck. in Linnaea*, xxxvi (1869–70) 491.—Forming compact grassy patches 2–6 in. diam. or more. Stems numerous, densely crowded, much branched at the base, stout or slender, striate, leafy at the base, 1–6 in. high. Leaves 2–6, equalling or longer than the stems, stout or slender, usually more or less coriaceous and rigid but sometimes almost flaccid, semiterete, convex on the back, grooved in front, tips obtuse. Spikelet solitary or rarely 2, small, $\frac{1}{12}$–$\frac{1}{8}$ in. long, broadly ovoid, varying in colour from dark chestnut-brown to pale whitish-green; bract very long, leafy, obtuse at the tip. Glumes few, ovate, obtuse, concave, often with a thick excurrent keel, very variable in colour. Stamens 3 or 2. Style-branches 3. Nut elliptic-ovoid, compressed, trigonous with the angles rounded, white or pale-yellow, smooth but not polished.—*Cheesem. Man. N.Z. Fl.* (1906) 773. Isolepis Aucklandica *Hook. f. Fl. Antarct.* i (1844) 88, t. 50; *Handb. N.Z. Fl.* (1864) 302. Isolepis cartilaginea *var.* rigida *Berggr. in Minnesk. Fisiog. Sallsk. Lund.* (1877) n. viii, 23. I. alpina *Hook. f. Fl. Tasm.* ii (1860) 86 (*in part*).

Var. **subcucullata** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 773.—Much more slender and diffuse. Stems weak, almost filiform; spikelet pale, solitary, 3–6-flowered. Glumes slightly hooded at the tip.—Isolepis subcucullata *Berggren, l.c.* 22, t. 5, f. 16–20.

North Island: Very plentiful around Tongariro and Ruapehu, *T. F. C.;* Rangipo Desert, *Petrie!* Ruahine Mountains, *Colenso!* ascending to 5000 ft.; Tararua Mountains, *B. C. Aston! Petrie!* South Island: Not uncommon in mountain-swamps throughout. Stewart Island, Auckland, Campbell, and Antipodes Islands: Plentiful in moist places, descending to sea-level. Macquarie Island: *H. Hamilton!*

A variable plant. The typical state can be recognized without much difficulty by the dense leafy habit, the leaves frequently overtopping the stems, by the small usually solitary spikelets, and pale elliptic-ovoid nut. But lowland states, with a more slender and less leafy habit, are difficult to separate from *S. cernuus*. Other forms approach very closely to *S. antarcticus*. According to Mr. C. B. Clarke, the species is also found in Tasmania and Amsterdam Island.

4. **S. cernuus** *Vahl. Enum.* ii (1806) 245.—Stems densely tufted, very slender, quite glabrous, 2–6 in. high, rarely more. Leaves setaceous, 1–3 near the base of the stem and shorter than it. Spikelets solitary or 2–3 together, ovoid or oblong-ovoid, $\frac{1}{10}$–$\frac{1}{5}$ in. long; bract variable in length, usually exceeding the spikelets, continuous with the stem so that the spikelets appear to be lateral. Glumes 6–15, broadly ovate, concave or obscurely keeled, obtuse or with a short point, green or chestnut-brown. Stamens 3, rarely 2 or 1. Style-branches 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, trigonous, obovoid, obtuse, minutely apiculate, not longitudinally ribbed, the surface appearing to be minutely reticulate from the numerous subquadrate cells.—*Cheesem. Man. N.Z. Fl.* (1906) 773. S. Savii *Sebast. and Mauri Prodr. Fl. Rom.* (1818) 22. S. riparius *Poir. Encycl. Suppl.* v, 103; *Benth. Fl. Austral.* vii (1878) 327. Isolepis riparia *R. Br. Prodr.* (1810) 222; *Hook. f. Fl. Tasm.* ii (1860) 89, t. 145c; *Handb. N.Z. Fl.* (1864) 302. I. setacea *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*in part, not of R. Br.*). I. setosa *Raoul Choix* (1846) 40.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands: Abundant throughout. Sea-level to 2000 ft. November–February.

Nearly cosmopolitan, being found in all temperate and tropical countries except south-eastern Asia. In New Zealand there are two principal forms: one, which is usually littoral, has the stems rather stiff, the spikelets usually solitary and often chestnut-brown, and the nut broadly obovoid; the other is more slender, the spikelets are paler, and the nut much smaller, more elliptical, and more acutely trigonous.

5. **S. antarcticus** (*Linn.*) *Mant.* ii (1771) 181.—Densely tufted, very variable in size, sometimes $\frac{1}{2}$–$1\frac{1}{2}$ in. high, stout, rigid, cartilaginous; at other times taller and more slender, 3–6 in. high or more. Leaves 1 or several at the base of the stem and shorter than it, obtuse at the tip, rigid and coriaceous in the smaller forms, softer and more grassy in the larger ones. Heads solitary, terminal, of 1–4 spikelets in the small stout forms, of 3–9 in the larger ones; bracts $\frac{1}{4}$–1 in. long, usually far exceeding the head. Spikelets rather stout, ovoid-oblong, $\frac{1}{8}$–$\frac{1}{5}$ in. long, many-flowered. Glumes broadly ovate, boat-shaped with a prominent keel, obtuse or the keel produced into a short point, often rigid and coriaceous, pale whitish-yellow with a conspicuous dark chestnut-brown spot; sides broad, marked with prominent curved lines; back often curved. Hypogynous scales wanting. Stamens 3 or 2, rarely 1. Style-branches 3. Nut rather more than $\frac{1}{2}$ as long as the glume, elliptic-ovoid, trigonous, acute, minutely punctate, white to yellow, sometimes ultimately almost black.—*C. B. Clarke in Fl. Cap.* vii (1898) 223; *Cheesem. Man. N.Z. Fl.* (1906) 774. S. cartilagineus *Poir. Encycl. Suppl.* v (1811) 103; *Benth. Fl. Austral.* vii (1878) 328. S. ebenocarpus *T. Kirk in Trans. N.Z. Inst.* xvii (1885) 224. Isolepis cartilaginea *R. Br. Prodr.* (1810) 222; *Hook. f. Fl. Nov. Zel.* i (1853) 271; *Fl. Tasm.* ii (1860) 88, t. 145; *Handb. N.Z. Fl.* (1864) 302.

North Island: Hawke's Bay—*Colenso! A. Hamilton!* Wellington—Karioi, Kaiwarawara, *T. Kirk!* South Island: Nelson—Cape Farewell, *T. Kirk!* Canterbury—Banks Peninsula, *A. Wall;* Burnham, *T. Kirk!* Springfield, *T. F. C.* Otago—Catlin's River, *Petrie!* Lake Wakatipu, *T. Kirk!* Bluff Hill, *T. Kirk!* Stewart Island: Port Pegasus, *Petrie! T. Krik!* Sea-level to 2000 ft. November–March.

Also in extratropical Australia, South Africa, and St. Helena.

6. **S. inundatus** *Poir. Encycl. Suppl.* v (1811) 103.—Very variable in size and habit of growth. Stems 2–12 in. high, often small, slender and filiform, at other times stouter and taller, and resembling small states of

S. sulcatus and *S. prolifer*. Leaves 1 or rarely 2 at the base of the stem, or reduced to a short and broad sheath. Heads solitary, terminal, of 2–15 crowded spikelets, often proliferous and putting out 1 or several short or long branches ending in a smaller head of spikelets; bract very variable in length. Spikelets $\frac{1}{10}$–$\frac{1}{4}$ in. long, ovate or ovate-oblong, subacute, pale or dark chestnut-brown, many-flowered. Glumes broadly ovate, concave or keeled at the back, obtuse or subacute, the sides usually more or less stained or striate with dark red-brown, the keel usually pale. Stamen 1. Style-branches 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, oblong-obovoid, equally and conspicuously trigonous, with a small conical point, not longitudinally ribbed, white, smooth but not polished.—*Benth. Fl. Austral.* vii (1878) 329. S. reticularis *Col. in Trans. N.Z. Inst.* xviii (1886) 277; *Cheesem. Man. N.Z. Fl.* (1906) 775. Isolepis inundata *R. Br. Prodr.* (1810) 222. I. prolifer *Hook. f. Handb. N.Z. Fl.* (1864) 301; *Fl. Tasm.* ii (1860) 87, t. 144 (*not of R. Br.*). I. setacea *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*in part, not of R. Br.*).

Var. **major**.—Stems tall and stout, 5–12 in. high, usually leafless. Spikelets more numerous, 6–15, densely compacted. Glumes obtuse. Approaches small forms of *S. sulcatus*, but is at once distinguished by the smaller acutely trigonous nut.

Var. **gracillima**.—Stems slender, often filiform, 2–6 in. long. Spikelets 2–6,

223.

Scirpus platycarpus S. T. Blake in Proceed. R.S.Q. LI (2) 1940, p.180.

tufted, 8–16 in. high, stout, grooved when dry, leafless except a large purple or purplish-black sheath at the base. Heads solitary, terminal, of 6–20 densely packed spikelets, often proliferous and emitting 1 or several branches ending in a smaller head of spikelets; bract variable in length. Spikelets rather short, $\frac{1}{8}$–$\frac{1}{4}$ in. long, oblong, obtuse, many-flowered. Glumes broadly ovate, obtuse, concave, dark chestnut-brown with a green keel and pale margins. Hypogynous bristles wanting. Stamens usually 1. Style-branches 2, rarely 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, obovoid, plano-convex, the convex side not keeled, smooth and polished, shining, white or pale yellowish-white.—Isolepis prolifer *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*for the most part, but not of R. Br., nor of Hook. f.*); *Handb. N.Z. Fl.* (1864) 301.

North and South Islands: Apparently common: Auckland—Hokianga, *Berggren;* Whangarei, *H. Carse!* vicinity of Auckland, *Petrie! T. F. C.;* Rotorua, *Cartwright, Petrie! T. F. C.;* Taupo, *T. Kirk!* Hawke's Bay—Norsewood, *Colenso!* Wellington—Murimotu, *Petrie!* Canterbury—Styx River, *Petrie!* Banks Peninsula, *R. M. Laing!* near Ashburton, *H. H. Allan.* Sea-level to 2000 ft. November–March.

For the identification of this plant with the Tristan d'Acunha *S. sulcatus* I am indebted to Mr. C. B. Clarke, who, however, maintains it as a distinct variety, characterized by the usually 2-fid style and plano-convex nut not keeled on the convex face. Large stout forms of *S. inundatus* approach it very closely, but in fruit are easily distinguished by the 3-fid style and acutely trigonous nut. *S. prolifer*, which has precisely the same habit of growth, can always be separated by the long linear spikelets, 3 stamens, and small acutely trigonous nut.

S. nervosus T. Kirk 1885 17: 224.

1. cernua (Vahl) Roem. et Schult. 1817

4. **S. cernuus** *Vahl. Enum.* ii (1806) 245.—Stems densely tufted, very slender, quite glabrous, 2–6 in. high, rarely more. Leaves setaceous, 1–3 near the base of the stem and shorter than it. Spikelets solitary or 2–3 together, ovoid or oblong-ovoid, $\frac{1}{10}$–$\frac{1}{5}$ in. long; bract variable in length, usually exceeding the spikelets, continuous with the stem so that the spikelets appear to be lateral. Glumes 6–15, broadly ovate, concave or obscurely keeled, obtuse or with a short point, green or chestnut-brown. Stamens 3, rarely 2 or 1. Style-branches 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, trigonous, obovoid, obtuse, minutely apiculate, not longitudinally ribbed, the surface appearing to be minutely reticulate from the numerous subquadrate cells.—*Cheesem. Man. N.Z. Fl.* (1906) 773. S. Savii *Sebast. and Mauri Prodr. Fl. Rom.* (1818) 22. S. riparius *Poir. Encycl. Suppl.* v, 103; *Benth. Fl. Austral.* vii (1878) 327. Isolepis riparia *R. Br. Prodr.* (1810) 222; *Hook. f. Fl. Tasm.* ii (1860) 89, t. 145c; *Handb. N.Z. Fl.* (1864) 302. I. setacea *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*in part, not of R. Br.*). I. setosa *Raoul Choix* (1846) 40.

3.

Also in extratropical Australia, South Africa, and St. Helena.

(R.Br.)

6. **S. inundatus** *Poir. Encycl. Suppl.* v (1811) 103.—Very variable in size and habit of growth. Stems 2–12 in. high, often small, slender and filiform, at other times stouter and taller, and resembling small states of

S. sulcatus and *S. prolifer*. Leaves 1 or rarely 2 at the base of the stem, or reduced to a short and broad sheath. Heads solitary, terminal, of 2–15 crowded spikelets, often proliferous and putting out 1 or several short or long branches ending in a smaller head of spikelets; bract very variable in length. Spikelets $\frac{1}{10}$–$\frac{1}{4}$ in. long, ovate or ovate-oblong, subacute, pale or dark chestnut-brown, many-flowered. Glumes broadly ovate, concave or keeled at the back, obtuse or subacute, the sides usually more or less stained or striate with dark red-brown, the keel usually pale. Stamen 1. Style-branches 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, oblong-obovoid, equally and conspicuously trigonous, with a small conical point, not longitudinally ribbed, white, smooth but not polished.—*Benth. Fl. Austral.* vii (1878) 329. S. reticularis *Col. in Trans. N.Z. Inst.* xviii (1886) 277; *Cheesem. Man. N.Z. Fl.* (1906) 775. Isolepis inundata *R. Br. Prodr.* (1810) 222. I. prolifer *Hook. f. Handb. N.Z. Fl.* (1864) 301; *Fl. Tasm.* ii (1860) 87, t. 144 (*not of R. Br.*). I. setacea *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*in part, not of R. Br.*).

Var. **major**.—Stems tall and stout, 5–12 in. high, usually leafless. Spikelets more numerous, 6–15, densely compacted. Glumes obtuse. Approaches small forms of *S. sulcatus*, but is at once distinguished by the smaller acutely trigonous nut.

Var. **gracillima**.—Stems slender, often filiform, 2–6 in. long. Spikelets 2–6, attened. Glums often subacute.

North and South Islands, Stewart Island, Chatham Islands: Abundant hroughout. Sea-level to 3000 ft. November–March.

As defined above, this varies so much in habit and other respects as to give rise o the suspicion that more species than one are included in it; but I have failed to d valid distinguishing characters. It extends through Australia to the Malay Archielago, and is also abundant in temperate South America.

7. **S. sulcatus** *Thouars Esquisse Fl. Trist.* 36, t. 7; var. **distigmatosa** . *B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 775.—Stems numerous, tufted, 8–16 in. high, stout, grooved when dry, leafless except a large purple or purplish-black sheath at the base. Heads solitary, terminal, of 6–20 densely packed spikelets, often proliferous and emitting 1 or several branches ending in a smaller head of spikelets; bract variable in length. Spikelets rather short, $\frac{1}{8}$–$\frac{1}{4}$ in. long, oblong, obtuse, many-flowered. Glumes broadly ovate, obtuse, concave, dark chestnut-brown with a green keel and pale margins. Hypogynous bristles wanting. Stamens usually 1. Style-branches 2, rarely 3, long, linear. Nut about $\frac{1}{2}$ the length of the glume, obovoid, plano-convex, the convex side not keeled, smooth and polished, shining, white or pale yellowish-white.—Isolepis prolifer *Hook. f. Fl. Nov. Zel.* i (1853) 271 (*for the most part, but not of R. Br., nor of Hook. f.*); *Handb. N.Z. Fl.* (1864) 301.

North and South Islands: Apparently common: Auckland—Hokianga, *Berggren;* Whangarei, *H. Carse!* vicinity of Auckland, *Petrie! T. F. C.;* Rotorua, *Cartwright, Petrie! T. F. C.;* Taupo, *T. Kirk!* Hawke's Bay—Norsewood, *Colenso!* Wellington—Murimotu, *Petrie!* Canterbury—Styx River, *Petrie!* Banks Peninsula, *R. M. Laing!* near Ashburton, *H. H. Allan.* Sea-level to 2000 ft. November–March.

For the identification of this plant with the Tristan d'Acunha *S. sulcatus* I am indebted to Mr. C. B. Clarke, who, however, maintains it as a distinct variety, characterized by the usually 2-fid style and plano-convex nut not keeled on the convex face. Large stout forms of *S. inundatus* approach it very closely, but in fruit are easily distinguished by the 3-fid style and acutely trigonous nut. *S. prolifer*, which has precisely the same habit of growth, can always be separated by the long linear spikelets, 3 stamens, and small acutely trigonous nut.

8. **S. prolifer** *Rottb. Descr. et Ic.* (1773) 55, t. 17, f. 2.—Stems numerous, tufted, 1–2 ft. high or more, rather stout, striate when dry, leafless except a large purplish or purplish-black sheath at the base. Heads large, ½–1 in. diam., terminal, solitary, of very many (10–30) densely crowded spikelets, often proliferous and putting out 1 or several usually long branches terminating in a much smaller head of spikelets; bract shorter than the head, obtuse. Spikelets long and narrow, ⅕–½ in. long, linear or linear-oblong, cylindrical, obtuse, many-flowered. Glumes ovate, obtuse, concave, chestnut-brown with a paler keel and margins. Hypogynous bristles wanting. Stamens 3. Style-branches 3, long, linear. Nut rather small, less than ½ the length of the glume, elliptic-ovoid, acute, acutely trigonous, smooth, pale yellowish-brown or almost white.—*Benth. Fl. Austral.* vii (1878) 330; *Cheesem. Man. N.Z. Fl.* (1906) 776. Isolepis prolifera *R. Br. Prodr.* (1810) 223. I. globosa *Buch. in Trans. N.Z. Inst.* iii (1871) 211.

North Island: Auckland—Bay of Islands, *T. Kirk!* Wellington—Karori, Evans Bay, and other localities in the vicinity of the City of Wellington, *Buchanan! T. Kirk! Petrie! B. C. Aston!* Wairarapa, *T. Kirk!* November–March.

Also in New South Wales, and abundant in South Africa. Easily separated from *S. sulcatus* and large states of *S. inundatus* by the very numerous long and narrow spikelets, and flowers with 3 stamens.

9. **S. nodosus** *Rottb. Descr. et Ic.* (1773) 52, t. 8, f. 3.—Rhizome short, stout, woody, creeping, ¼ in. diam. or more. Stems very numerous, closely packed, 1–3 ft. high, erect, rigid, terete or slightly compressed. Leaves wanting except 2 or 3 sheathing scales at the base of the stems. Head solitary, globose, brown, ⅓–⅔ in. diam., of very numerous densely crowded spikelets; bract ½–1½ in. long, rigid, erect, continuous with the stem, so that the head appears lateral. Spikelets ovoid, ⅙–⅕ in. long, many-flowered. Glumes broadly ovate, obtuse or obscurely mucronate, concave. Hypogynous bristles wanting. Stamens 3. Style-branches 3, linear. Nut less than ½ the length of the glume, obovoid, obtusely trigonous, the flat face next the glume, pale-brown, smooth and polished.—*Benth. Fl. Austral* vii (1878) 331; *Cheesem. Man N.Z. Fl.* (1906) 776. Isolepis nodosa *R. Br. Prodr.* (1810) 221; *A. Rich. Fl. Nouv. Zel.* (1832) 104; *A. Cunn. Precur.* (1836) n. 272; *Raoul Choix* (1846) 40; *Hook f. Fl. Nov. Zel.* i (1853) 270; *Handb. N.Z. Fl.* (1864) 301.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant throughout. Sea-level to 2000 ft. November–February.

Also found in Norfolk Island and Lord Howe Island, temperate Australia, extra-tropical South Africa, St. Helena and Amsterdam Islands, and temperate South America.

10. **S. frondosus** *Banks and Sol. ex Boeck. in Flora*, lxi (1878) 141.—Stout, rigid, harsh, yellow-green, 2–3 ft. high. Rhizome thick, woody, creeping, often many feet in length. Stems many along the rhizome, stout, erect, obtusely trigonous, leafy at the base. Leaves very numerous, spreading, often curved, rigidly coriaceous, channelled above, keeled beneath, gradually narrowed into long trigonous points, at the base expanded into broad membranous sheaths; margins and keel sharply denticulate. Inflorescence 3–9 in. long or more, of linear clusters of densely crowded sessile spikelets arranged in a spiral manner around the upper part of the stem, each cluster subtended by a rigid linear bract similar to the leaves. Spikelets red-brown, almost globose, about ⅛ in. long, many-flowered.

Glumes broadly ovate, obtuse, concave, shining, striate. Hypogynous bristles wanting. Stamens 3; anthers with a long awn. Style-branches 3. Nut broadly obovoid, compressed, quite smooth.—*Cheesem. Man. N.Z. Fl.* (1906) 777; *C. B. Clarke Ill. Cyp.* (1909) t. liii, f. 1–3. Isolepis spiralis *A. Rich. Fl. Nouv. Zel.* (1832) 105, t. 19; *A. Cunn. Precur.* (1836) n. 274; *Raoul Choix* (1846) 40. Desmoschoenus spiralis *Hook. f. Fl. Nov. Zel.* i (1853) 272; *Handb. N.Z. Fl.* (1864) 303. Anthophyllum Urvillei *Steud. Syn. Pl. Cyp.* (1855) 160.

North and South Islands, Chatham Islands: Abundant on sand-dunes from the North Cape to Otago. Stewart Island: Abundant, *Cockayne. Pingao.* November-February.

The leaves were formerly used by the Maoris for making kits, and occasionally for cloaks, which were said to be very durable.

11. **S. americanus** *Pers. Syn.* i (1805) 68.—Rhizome creeping. Stems rather slender, 1–2 ft. high, acutely trigonous. Leaves 1–4, always shorter than the stem; sheaths long. Head small, of 1–4 closely compacted sessile spikelets; bract 1–2 in. long, erect, angular, continuous with the stem so that the head appears lateral. Spikelets broadly ovoid, $\frac{1}{4}$–$\frac{1}{3}$ in. long, dark-brown, many-flowered. Glumes broadly ovate, membranous, concave, tip emarginate with usually a short awn in the notch, margins scarious above. Hypogynous bristles 4–6, shorter than the nut. Stamens 3. Style-branches 2–3. Nut rather large, $\frac{2}{3}$ the length of the glume, obovoid, plano-convex, pale-brown, smooth.—*Cheesem. Man. N.Z. Fl.* (1906) 777. S. pungens *Vahl. Enum.* ii (1806) 255; *Benth. Fl. Austral.* vii (1878) 333. S. triqueter *R. Br. Prodr.* (1810) 223; *Hook. f. Fl. Nov. Zel.* i (1853) 269; *Handb. N.Z. Fl.* (1864) 300 (*not of Linn.*). S. novae-zealandiae *Col. in Trans. N.Z. Inst.* xviii (1886) 277.

North and South Islands, Chatham Islands: Brackish-water swamps from Hokianga to Foveaux Strait, but often local. Inland at Roxburgh, Otago, *Petrie!* November–February.

Not uncommon in temperate Australia and Tasmania, North and South America, and southern Europe.

12. **S. lacustris** *Linn. Sp. Plant.* (1753) 48.—Rhizome stout, creeping, with numerous perpendicular rootlets. Stems 2–6 ft. high, sometimes almost as thick as the finger, terete, spongy, glaucous. Leaves wanting, or the uppermost sheath with a very short flat lamina. Inflorescence a terminal simple or compound cymose umbel 2–4 in. across; rays few, stout, irregular; bract shorter than the umbel, continuous with the stem. Spikelets numerous, ovoid or oblong, $\frac{1}{3}$ in. long, brownish, many-flowered. Glumes broadly ovate, membranous, concave, notched at the tip with a small point in the notch, margins fringed. Hypogynous bristles 5–6, linear, retrorsely scabrid, usually equalling the nut. Stamens 3. Style-branches 3 or 2. Nut more than $\frac{1}{2}$ as long as the glume, obovoid, compressed, plano-convex, pale-brown, smooth.—*A. Rich. Fl. Nouv. Zel.* (1832) 103; *A. Cunn. Precur.* (1836) n. 275; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 269; *Handb. N.Z. Fl.* (1864) 300; *Benth. Fl. Austral.* vii (1878) 333; *Cheesem. Man. N.Z. Fl.* (1906) 778.

North and South Islands: Margins of lakes and ponds from the North Cape southwards to the north of Otago and Okarito, common. Sea-level to 1500 ft. November–February.

Generally distributed in all temperate and warm countries, except South America.

13. **S. maritimus** *Linn. Sp. Plant.* (1753) 74.—Rhizome woody, creeping, the nodes often dilated into hard tubers. Stems stout, sharply triangular, 1–3 ft. high or more. Leaves from near the base of the stem and often exceeding it, broad, flat, grassy. Inflorescence an irregular terminal umbel of few unequal rays, often contracted into a compact cluster; bracts 3–4, 3–9 in. long, similar to the leaves. Spikelets $\frac{1}{2}$–$\frac{3}{4}$ in. long, sessile or peduncled, ovoid or cylindric, brown, many-flowered. Glumes ovate, membranous, 2-lobed at the tip with a short intermediate awn, usually pubescent towards the tip. Hypogynous bristles 3–6, shorter than the nut, retrorsely scabrid. Stamens 3. Style-branches 3 or 2, long, linear. Nut less than $\frac{1}{2}$ the length of the glume, broadly obovoid, compressed, flat on one side, convex or obtusely angled on the other, smooth and polished, brown when fully ripe.—*Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 269; *Handb. N.Z. Fl.* (1864) 300; *Cheesem. Man. N.Z. Fl.* (1906) 778. See Britton & Brown I. 326.

Var. **fluviatilis** *Torr. in Ann. Lyceum New York*, iii (1836) 324.—Taller and stouter, 3–6 ft. high. Leaves broader, $\frac{1}{2}$ in. diam. or more; bracts longer. Umbel larger, more often compound; rays 3–9. Spikelets large, pale-brown. Style-branches 3. Nut narrower, oblong-obovoid, trigonous, conspicuously beaked, white or pale-brown, opaque, polished.—*Benth. Fl. Austral.* vii (1878) 335. S. fluviatilis *Asa Gray Man. Bot. U.S.* (1856) 500. (Tau)

Var. **macrostachya** *Michx. Fl. Bor. Amer.* v (1803) 32.—Umbels simple or compound. Spikelets large, sometimes over 1 in. long. Style-branches almost always 2. Nut large, broadly obovoid, flat on one side and obscurely angled on the other, white or pale-brown, opaque, not polished.—*Asa Gray Man. Bot. U.S.* (1856) 500. S. robustus Pursh.

North and South Islands: The two varieties not uncommon in brackish-water swamps and on the banks of lakes and streams from the North Cape to Otago Harbour. November–February.

In the North Island var. *fluviatilis* extends inland along most of the larger rivers, ascending the Waikato as far as Lake Taupo. Var. *macrostachya* seems to be chiefly found in brackish-water swamps. Both varieties are abundant in North America, and also in Australia and Tasmania. According to Mr. C. B. Clarke, the typical form of the species has not yet been observed in either Australia or New Zealand.

7. CARPHA R. Br. 1810

Perennial herbs. Leaves crowded at the base of the stem, usually shorter than it. Spikelets numerous, narrow, 1-flowered, arranged in a terminal corymb or panicle, sometimes contracted into a more or less dense head. Glumes usually 4, distichous; the 2 lowest small, empty; the third large, also empty; the uppermost about the same size, with a single hermaphrodite flower in its axil. Hypogynous bristles 6, plumose, much enlarged in fruit and exceeding the glumes. Stamens 3. Style-branches 3. Nut oblong, 3-angled, narrowed above into the persistent and hardened base of the style.

In addition to the New Zealand species, which is also found in Tasmania, Victoria, and on the mountains of New Guinea, there are 2 or 3 closely allied species in Chile and Fuegia.

1. **C. alpina** *R. Br. Prodr.* (1810) 230.—A tufted grass-like herb 3–12 in. high. Leaves usually shorter than the stems, numerous, narrow-linear, rigid, obtuse at the tip, flat or concave, grooved, dilated at the base into broad membranous sheaths. Spikelets $\frac{1}{3}$–$\frac{1}{2}$ in. long, lanceolate, compressed, arranged in a corymbose manner at the top of the stem, in small specimens

...warding. Nut oblong, obtuse, not trigonous, white .. 3. *S. Carsei.*
Stems 1–3 ft., slender. Spikelets few (2–8), ¼ in. Hypogynous bristles present, very long. Nut elliptic, trigonous, pale-brown .. 4. *S. pauciflorus.*

** Stems shorter, not so rigid, often diffuse. Leaves well developed. Spikelets fascicled or umbelled, sometimes solitary.

Stems 2–6 in., creeping or diffuse. Leaves alternate, spreading. Spikelets 1–3 in the axils of the leaves .. .. .. 5. *S. axillaris.*
Stems 6–14 in., slender, diffuse. Leaves mostly at the base of the stems, linear. Spikelets in irregular umbels or fascicles .. 6. *S. apogon.*
Stems 1–12 in., slender, wiry, rigid. Leaves few at the base of the stems. Spikelets sessile in a dense head, sometimes few or solitary 7. *S. nitens.*

1. **S. brevifolius** *R. Br. Prodr.* (1810) 231.—Rhizome short, stout, creeping. Stems rush-like, densely tufted, rigid, erect, terete, smooth and polished, 1–2 ft. high. Leaves reduced to 3 or 4 dark red-brown appressed sheaths at the base of the stem, the uppermost of which has a short rigid erect subulate lamina ½–1 in. long. Panicle narrow, 3–8 in. long; branches slender, erect; bracts at the base with appressed sheaths

TN.Z.T.56:9.
1929

SCHOENUS CAESPITANS Petrie. Species dense caespitans depressa c. 4 cm. (1-1½ in. alta. Folia a bas erecta, filiformia, culmos aequantia vel excedentia, basi = expansa ac vaginantia; culmi folius crassiores virides erecti; inflorescentia brevis capituliformis; capitulum parvum sublonge bracheatum, e fasciculis tribus 8-10 florigeris arcte aggregatis compositum; glumae distichae 3 inferiores vacuae, quarta florem hermaphrodit gerens, summa vacuo raro staminifera; setae plerumque 3; stylus erectus supra in ramos 3 divaricantes divisus; spiculae culmique maturi haud visi. Ure Valley, A. Wall.

TN.T.I. 56.50 1926.

"Schoenus fluitans Hook. A slender, spreading much-branched water or mud plant; branches slender. Leaves slender, filiform, mostly 2 or 3 inches long, solitary at intervals or tufted at nodes. Spikelets usually solitary, at the ends of the branches, linear, 4 or 5 lines long contained in 2 more or less glume-like bracts, 2-4 flowers, with only one or no empty glumes. Hypogynous bristles none. Stamens 3. Nut ovoid, prominently 3-ribbed." (Rodway).

shorter than it. Spikelets numerous, narrow, 1-flowered, arranged in a terminal corymb or panicle, sometimes contracted into a more or less dense head. Glumes usually 4, distichous; the 2 lowest small, empty; the third large, also empty; the uppermost about the same size, with a single hermaphrodite flower in its axil. Hypogynous bristles 6, plumose, much enlarged in fruit and exceeding the glumes. Stamens 3. Style-branches 3. Nut oblong, 3-angled, narrowed above into the persistent and hardened base of the style.

In addition to the New Zealand species, which is also found in Tasmania, Victoria, and on the mountains of New Guinea, there are 2 or 3 closely allied species in Chile and Fuegia.

1. **C. alpina** *R. Br. Prodr.* (1810) 230.—A tufted grass-like herb 3–12 in. high. Leaves usually shorter than the stems, numerous, narrow-linear, rigid, obtuse at the tip, flat or concave, grooved, dilated at the base into broad membranous sheaths. Spikelets ⅓–½ in. long, lanceolate, compressed, arranged in a corymbose manner at the top of the stem, in small specimens

crowded into a head. Bracts leafy, usually exceeding the inflorescence. Glumes rigidly membranous, linear-oblong, pale, shining, concave. Hypogynous bristles very large, in the fruiting stage exceeding the glumes, conspicuously plumose for their whole length. Nut narrow-oblong, prismatic, tipped by the long hardened base of the style.—*Hook. f. Fl. Nov. Zel.* i (1853) 273; *Fl. Tasm.* ii (1860) 84; *Handb. N.Z. Fl.* (1864) 299; *Benth. Fl. Austral.* vii (1878) 381, *and in Hook. Ic. Plant.* t. 1216.

North Island: Mountain districts from Moehau (Cape Colville) and the East Cape southwards. South Island, Stewart Island: Abundant in hilly and mountain districts throughout. Auckland Islands: Carnley Harbour, *T. Kirk!* Usually from 2500 to 5000 ft., but descends to sea-level in Stewart Island. December–February.

8. **SCHOENUS** Linn.

Usually perennial herbs, of very various habit, stout, erect and rush-like, or slender and diffuse, rarely creeping. Leaves near the base of the stem or cauline, sometimes reduced to sheathing scales. Spikelets compressed, few-flowered, panicled or capitate or fascicled. Glumes more or less distichous, 3 or more outer ones empty, 1–4 succeeding ones hermaphrodite and fruit-bearing, uppermost male or empty; rhachilla elongated and flexuose between the flowering glumes, with the flowers seated in the alternate notches. Hypogynous bristles present or wanting. Stamens usually 3, rarely fewer or 4–6. Style slender, sometimes slightly thickened near the base; style-branches 3. Nut obovoid, ovoid, or oblong, trigonous.

A large genus of about 70 species, mainly from Australia and New Zealand, but a few are widely distributed in the temperate regions of the Northern Hemisphere, and 2–3 are Malayan. Of the 7 species found in New Zealand, 3 are endemic, the remaining 4 extend to Australia and Tasmania.

* Stems densely tufted, erect, terete, rush-like. Leaves either reduced to appressed sheaths or a short erect lamina alone present. Spikelets in a narrow terminal panicle.

Stems 1–2 ft., rather stout. Spikelets many, $\frac{1}{3}$–$\frac{1}{2}$ in. long. Hypogynous bristles wanting. Nut trigonous, faces transversely rugose — 1. *S. brevifolius.*
Stems 1–3 ft., slender. Spikelets few or many, $\frac{1}{4}$ in. long. Hypogynous bristles present, equalling the nut or shorter than it. Nut obovoid, smooth .. .. — 2. *S. Tendo.*
Stems 1–2$\frac{1}{2}$ ft., very slender. Spikelets many, $\frac{1}{4}$–$\frac{1}{3}$ in. Hypogynous bristles wanting. Nut oblong, obtuse, not trigonous, white .. — 3. *S. Carsei.*
Stems 1–3 ft., slender. Spikelets few (2–8), $\frac{1}{4}$ in. Hypogynous bristles present, very long. Nut elliptic, trigonous, pale-brown .. — 4. *S. pauciflorus.*

** Stems shorter, not so rigid, often diffuse. Leaves well developed. Spikelets fascicled or umbelled, sometimes solitary.

Stems 2–6 in., creeping or diffuse. Leaves alternate, spreading. Spikelets 1–3 in the axils of the leaves .. .. .. — 5. *S. axillaris.*
Stems 6–14 in., slender, diffuse. Leaves mostly at the base of the stems, linear. Spikelets in irregular umbels or fascicles .. — 6. *S. apogon.*
Stems 1–12 in., slender, wiry, rigid. Leaves few at the base of the stems. Spikelets sessile in a dense head, sometimes few or solitary — 7. *S. nitens.*

1. **S. brevifolius** *R. Br. Prodr.* (1810) 231.—Rhizome short, stout, creeping. Stems rush-like, densely tufted, rigid, erect, terete, smooth and polished, 1–2 ft. high. Leaves reduced to 3 or 4 dark red-brown appressed sheaths at the base of the stem, the uppermost of which has a short rigid erect subulate lamina $\frac{1}{2}$–1 in. long. Panicle narrow, 3–8 in. long; branches slender, erect; bracts at the base with appressed sheaths

and a short erect lamina. Spikelets lanceolate, compressed, $\frac{1}{3}$–$\frac{1}{2}$ in. long, 2–3-flowered, red-brown. Glumes 6–9, distichous, ovate-lanceolate, acute, concave, nerveless; margins ciliate; the 4–6 outer smaller and empty. Hypogynous bristles wanting. Stamens usually 2. Style-branches 3. Nut small, turgid, obovoid, trigonous with the angles thickened, faces transversely rugose.—*Benth. Fl. Austral.* vii (1878) 170; *Cheesem. Man. N.Z. Fl.* (1906) 780. S. tenax *Hook. f. Handb. N.Z. Fl.* (1864) 298. Chaetospora tenax *Hook. f. Fl. Nov. Zel.* i (1853) 273.

North Island: From the North Cape to Cook Strait, but rare and local to the south of Rotorua. South Island: Nelson—Aorere Valley, *T. Kirk!* Sea-level to 1500 ft. December–January.

Also in extratropical Australia.

2. **S. Tendo** *Banks and Sol. ex Hook. f. Handb. N.Z. Fl.* (1864) 298.—Rhizome stout, creeping. Stems much more slender than in *S. brevifolius*, 1–3 ft. high, rigid, deeply grooved throughout their length. Leaves reduced to 2–3 dark chestnut-brown or almost black sheaths at the base of the stem, the uppermost produced into a subulate lamina $\frac{1}{4}$–$\frac{1}{2}$ in. long; the mouths of the sheaths fringed with cobwebby hairs. Panicle slender, narrow, 2–8 in. long; branches short, slender, erect. Spikelets linear-lanceolate, compressed, 2–4-flowered, $\frac{1}{4}$–$\frac{1}{3}$ in. long, dark-brown or almost black. Glumes 8–10, distichous, ovate-lanceolate, acute, concave, keeled, nerveless except the midrib; margins ciliate; the 5–6 outer smaller and empty. Hypogynous bristles 3–6, short, slender, sometimes not equalling the nut. Stamens 2. Style-branches usually 2. Nut obovoid, unequally and obliquely biconvex, quite smooth, white.—*Cheesem. Man. N.Z. Fl.* (1906) 781. Chaetospora Tendo *Hook. f. Fl. Nov. Zel.* i (1853) 273.

North Island: Abundant on clay hills from the North Cape to Hawke's Bay and Taranaki. South Island: Nelson—Aorere Valley, *T. Kirk.* Sea-level to 2000 ft. October–January.

Easily distinguished from the preceding species by the more slender grooved stems, smaller darker spikelets, the presence of bristles, and by the smooth biconvex nut.

3. **S. Carsei** *Cheesem. Man. N.Z. Fl.* (1906) 781.—Rhizome short, stout, creeping, clothed with chestnut-brown scales. Stems densely tufted, very slender, 1–2½ ft. high, terete, grooved. Leaves reduced to 2–3 chestnut-brown sheaths at the base of the stem, produced at the tip into an erect subulate lamina $\frac{1}{2}$–2 in. long; the mouths of the sheaths oblique, glabrous. Panicle slender, narrow, 2–6 in. long; branches filiform, erect; bracts at the base with appressed sheaths, and a short erect lamina. Spikelets numerous, compressed, very narrow, $\frac{1}{4}$–$\frac{1}{3}$ in. long, linear-lanceolate, acute, brownish. Glumes 5–7, distichous, closely imbricate, ovate-lanceolate, acuminate, concave, keeled, thin and membranous, nerveless; the 3–4 outer empty. Hypogynous bristles wanting. Stamens 3. Style-branches 3. Nut oblong, obtuse at both ends, not trigonous, smooth, white.—*Cheesem. Ill. N.Z. Fl.* ii (1914) t. 209.

North Island: Auckland—Rangaunu Harbour, *H. Carse!* swamps at Whangarei and between the Manukau Harbour and the Waikato River, *H. Carse!* Papatoetoe, *T. Kirk!* swamps by the Waitoa River, *P. H. Allen!* Taranaki—Ngaire Swamp, *T. F. C.* January–March.

This seems to have been confounded with *S. pauciflorus*, but differs from that species in the shorter leaves, longer panicle with numerous spikelets, in the absence of bristles, and in the nut. It is probably common in lowland swamps.

Schoenus fluitans Hk.f. see Cockayne Trans. 57: 1926: Wilmanina Pl. 90.

4. **S. pauciflorus** *Hook. f. Handb. N.Z. Fl.* (1864) 298.—Rhizome short, stout, branched at the tip. Stems densely tufted, very slender, deeply grooved, 1–3 ft. high, green or purplish-red. Leaves reduced to 2–4 dark chestnut-brown or almost black sheaths at the base of the stem, the uppermost of which is produced into an erect almost filiform lamina 1–3 in. long; the mouths of the sheaths oblique, glabrous. Panicle small, $\frac{3}{4}$–2 in. long, of 2–8 spikelets; bracts usually 2, overtopping the panicle. Spikelets lanceolate, compressed, $\frac{1}{4}$ in. long, 2–4-flowered, varying in colour from whitish to dark chestnut-brown. Glumes 4–6, distichous, ovate-lanceolate, acuminate, keeled, nerveless except the midrib; margins glabrous; the 3 outer slightly smaller, empty. Hypogynous bristles 6, filiform, almost equalling the style. Stamens 3. Style-branches 3. Nut elliptic-oblong, trigonous with the angles thickened, smooth, polished, pale-brown.—*Cheesem. Man. N.Z. Fl.* (1906) 782. Chaetospora pauciflora *Hook. f. Fl. Nov. Zel.* i (1853) 273.

North and South Islands, Stewart Island: An abundant mountain-plant from Lake Taupo southwards. Usually from 1500 to 5500 ft., but descends to sea-level in Stewart Island and the south of Otago. December–March.

This hardly differs from the Chilian *Chaetospora antarctica* Hook. f., except in the much shorter leaves.

R.Sa. S. foliatus (Hk.f.) S.T. Blake. Proc. Roy. Soc. Qld. 51: 48 1940:

5. **S. axillaris** *Poir. Encycl. Suppl.* ii (1811) 251.—Stems very slender, pale-green, flaccid, leafy, branched, creeping or diffusely spreading, often intricate, 2–6 in. long or more. Leaves alternate, spreading, $\frac{1}{2}$–1 in. long, very narrow-linear, obtuse, flat or nearly so, flaccid. Spikelets 1–3 together in the axils of the leaves, sessile or shortly peduncled, about $\frac{1}{10}$ in. long, compressed, pale-brown, 1–2-flowered. Glumes distichous, lanceolate, subacute, keeled; the 2 or 3 outer empty and smaller. Hypogynous bristles 6, rarely fewer, longer than the nut. Stamens 3. Style-branches 3. Nut very small, elliptic-obovoid, obtusely trigonous, quite smooth, white or greyish-white.—*Hook. f. Handb. N.Z. Fl.* (1864) 298; *Benth. Fl. Austral.* vii (1878) 375; *Cheesem. Man. N.Z. Fl.* (1906) 788. Chaetospora axillaris *R. Br. Prodr.* (1810) 233; *Hook. f. Fl. Nov. Zel.* i (1853) 274, t. 62A; *Fl. Tasm.* ii (1860) 82. Scirpus foliatus *Hook. f. in Lond. Journ. Bot.* iii (1844) 414. Bot. Soc. Bot. Exch. Cl. 1941. 17: 124.

North and South Islands, Stewart Island, Chatham Islands: From the North Cape southwards, abundant in the North Island, less plentiful in the South Island. Sea-level to 2500 ft. November–March.

Easily recognized by the slender creeping or diffuse habit, leafy stems, spikelets in twos or threes in the axils of the leaves, and small white nut. Also common in extra-tropical Australia and Tasmania.

6. **S. apogon** *Roem. and Schult. Syst.* ii (1817) 77.—Stems very numerous, crowded, weak, slender, sometimes almost filiform, grooved, leafy at the base, 6–14 in. long. Leaves much shorter than the stems, narrow-linear, acute, almost flaccid, channelled in front, convex and striate on the back. Spikelets linear-lanceolate, chestnut-brown or almost black, $\frac{1}{8}$–$\frac{1}{6}$ in. long, 1–3-flowered, few or many together in irregular more or less compact umbels or heads, which are both terminal and lateral from the upper leaf-sheaths; bracts leafy. Glumes distichous, oblong-lanceolate, acute, keeled, almost black with narrow pale margins; the 3 outer empty, usually much smaller. Hypogynous bristles 6, not much exceeding the nut. Stamens 3. Style-branches usually 3. Nut small, broadly oblong-

obovoid, obtusely trigonous, conspicuously reticulated, white. — *Cheesem. Man. N.Z. Fl.* (1906) 783. S. Brownii *Hook. f. Handb. N.Z. Fl.* (1864) 298; *Benth. Fl. Austral.* vii (1878) 373. Chaetospora imberbis *R. Br. Prodr.* (1810) 233; *Hook. f. Fl. Nov. Zel.* i (1853) 274; *Fl. Tasm.* ii (1860) 82.

Var. **laxiflorus** *C. B. Clarke.* — Stems very slender, lax, sometimes 2 ft. long. Inflorescence much more lax; clusters mostly lateral; spikelets often long-peduncled. —S. laxiflorus *Steud. Cyp.* (1855) 166. S. vaccilans *T. Kirk in Trans. N.Z. Inst.* x (1878) 421.

North Island: Auckland—Cape Maria van Diemen and Tapotopoto Bay, *H. Carse!* Mangonui, *T. F. C.;* Puhipuhi, *T. Kirk;* Whangarei, *H. Carse!* vicinity of Auckland, *T. F. C., Petrie!* East Coast, *W. Colenso!* Var. *laxiflorus:* Between Taheke and Opaneke, *Petrie!* ravines near the base of Mount Wynyard, *T. Kirk!* between Te Aroha and Katikati, *Adams!* Taranaki—White Cliffs, *T. F. C.* South Island: Canterbury—Kowai Pass, *T. Kirk!* (the typical form). Sea-level to 2000 ft. December–March.

Common in eastern Australia, from Queensland to Tasmania.

7. **S. nitens** *Poir. Encycl. Suppl.* ii (1811) 251. — Rhizome slender, creeping. Stems densely tufted, slender, wiry, grooved, leafy at the base, 2–12 in. high. Leaves few, shorter than the stems, semiterete, deeply channelled in front, grooved on the back; sheaths chestnut-brown or blackish-brown, shining, grooved. Inflorescence a terminal head of 1–15 densely crowded and sessile spikelets; bracts $\frac{1}{2}$–1 in. long, exceeding the spikelets, continuous with the stem, so that the head appears lateral. Spikelets ovoid to lanceolate-ovoid, somewhat turgid, $\frac{1}{8}$–$\frac{1}{5}$ in. long, 2- or more rarely 3-flowered, chestnut-brown to blackish-brown. Glumes 4–6, obscurely distichous, broadly ovate, obtuse, concave, keeled, shining; the 2 or rarely the 3 outer smaller and empty. Hypogynous bristles 6, usually longer than the nut, plumose at the base with long hairs. Stamens 3. Style-branches 3. Nut ovoid, obscurely trigonous, smooth and shining, pale-brown to dark-brown.—*Hook. f. Handb. N.Z. Fl.* (1864) 299; *Benth. Fl. Austral.* vii (1878) 362; *Cheesem. Man. N.Z. Fl.* (1906) 783. S. Moorei *T. Kirk in Trans. N.Z. Inst.* xiii (1881) 384 (*not of Benth.*). Chaetospora nitens *R. Br. Prodr.* (1810) 233; *Hook. f. Fl. Nov. Zel.* i (1853) 274; *Fl. Tasm.* ii (1860) 82. Scirpus nitens *Boeck. in Linnaea,* xxxvi (1869–70) 696.

Var. **concinnus.**—Smaller, more rigid and wiry, 1–3 in. high. Spikelets solitary or rarely 2 together, slightly compressed, $\frac{1}{6}$–$\frac{1}{5}$ in. long, dark-brown or almost black. Nut rather larger, broadly ovoid, trigonous, sometimes scabrid at the tip.—S. concinnus *Hook. f. Handb. N.Z. Fl.* (1864) 299. Chaetospora concinna *Hook. f. Fl. Nov. Zel.* i (1853) 274, t. 62, f. B. Ascends to 4500 ft. on Ruapehu.

North and South Islands, Stewart Island: From Lake Taupo southwards, but often local. Sea-level to 2500 ft. December–March.

A most variable plant. Hooker's *S. concinnus* appears to me to be a depauperated state connected with the type by numerous intermediates, and I have consequently followed Mr. C. B. Clarke in reducing it to *S. nitens.* The typical form is not uncommon in Australia, ranging from Queensland to Tasmania and Western Australia.

9. CLADIUM P. Browne.

Perennial herbs. Stems stout or slender, terete or compressed, sometimes leafy throughout, sometimes at the base only, or the leaves reduced to sheathing scales. Leaves terete or compressed, more rarely vertically flattened and equitant at the base. Inflorescence paniculate. Spikelets numerous, rarely few, 1–3- or rarely 4–6-flowered, the lowest flower always perfect and fruit-bearing. Glumes imbricate all round, 1–4 outer empty,

smaller than the succeeding flowering ones. Hypogynous bristles usually wanting. Stamens 3. Style long, linear; base often dilated but continuous with the nut; style-branches 3, rarely 2. Nut ovoid or oblong, terete or obscurely trigonous or tricostate, smooth, crowned by the adnate base of the style.

Species between 40 and 50, widely distributed, but more plentiful in the Southern Hemisphere than in the Northern. Of the 10 species found in New Zealand, 6 extend to Australia and Tasmania, 3 of them being also found in the Pacific islands or eastern Asia; the remaining 4 are endemic.

taken up by G. stalk

A. Vincentia. *Spikelets with 2–4 perfect flowers. Nut stipitate, triquetrous, narrowed upwards into a long cuspidate beak.*

Tall, 2–5 ft. Stems and leaves flattened, the latter ½–1 in. broad. Panicle very large, lax, drooping .. .. 1. *C. Sinclairii.*

B. Baumea. *Spikelets with 1 or rarely 2 perfect flowers. Nut sessile, often tumid at the apex, not narrowed into a cuspidate beak.*

* Spikelets usually 2–3-flowered, 1 or sometimes 2 of the flowers perfecting fruit.

Stems and leaves flattened, ¼–½ in. broad. Panicle 6–12 in., narrow. Nut ovoid, trigonous .. .. 2. *C. complanatum.*
Stems and leaves stout, terete, transversely septate. Panicle very large and broad, drooping. Nut obovoid, trigonous .. .. 3. *C. articulatum.*
Stems and leaves slender, terete, not septate. Panicle narrow, erect, 3–10 in. long, interrupted; bracts spathaceous. Nut reddish-yellow, trigonous .. .. 4. *C. glomeratum.*
Stems and leaves slender, terete, not septate. Panicle narrow, 10–18 in.; branches drooping. Nut pale .. .. .. 5. *C. Huttoni.*

** Spikelets 1- or rarely 2-flowered, never more than one flower perfecting fruit.

Stems and leaves slender, terete. Panicle 2–6 in. long, stiff, dense; bracts small. Nut small, oblong-orbicular .. .. .. 6. *C. teretifolium.*
Stems very slender, terete. Leaf solitary and long, or reduced to sheathing scales. Panicle 6–18 in. long, slender. Nut ovoid, smooth; tip large, tumid .. .. 7. *C. Gunnii.*
Stems terete. Leaves reduced to sheathing scales. Panicle short, ½–1½ in. long. Nut obtusely trigonous, tip small, puberulous .. 8. *C. junceum.*
Stems stout, tetragonous. Leaves like the stems, short, often reduced to sheathing scales. Panicle contracted into a spike ⅓–½ in. long. Hypogynous bristles present .. .. 9. *C. Vauthiera.*
Stems filiform. Leaves reduced to sheathing scales. Panicle short, ½–¾ in. long; spikelets 3–7. Nut with a persistent style-base as long as itself .. .. 10. *C. capillaceum.*

v. anceps Hk. f.

1. **C. Sinclairii** *Hook. f. Handb. N.Z. Fl.* (1864) 305.—Stems tall, leafy, quite flat, smooth, 2–5 ft. high, ¼ in. diam., forming large clumps. Leaves 2–4 ft. long, distichous and equitant at the base, acuminate, quite flat, ½–1 in. broad, pale-green, smooth, striate; margins thin, even. Panicle large, terminal, nodding, excessively branched, 9–12 in. long or more; bracts sheathing, 2-edged; branches drooping. Spikelets innumerable, rich dark red-brown, fascicled, ⅛ in. long, 2–3-flowered, the lower flower usually alone fertile. Glumes usually 5, ovate-lanceolate, acuminate or almost awned, minutely scabrid-pubescent, 2 or 3 outer empty. Hypogynous bristles wanting. Stamens 3, elongating after flowering. Style-branches 3. Nut small, red-brown, fusiform, trigonous, conspicuously narrowed at the base, and also upwards into a triquetrous minutely scabrid beak.—*Cheesem. Man. N.Z. Fl.* (1906) 785; *Ill. N.Z. Fl.* ii (1914) t. 211. C. gahnioides *Col. in Trans. N.Z. Inst.* xvi (1884) 340. Vincentia anceps *Hook. f. Fl. Nov. Zel.* i (1853) 276. V. gladiata *Boeck. in Linnaea*, xxxviii (1874) 250.

Scirpus anceps. Sol. in L. p. 76.

North Island: From the North Cape southwards to Taupo, Hawke's Bay, the Wanganui River, and the Ruahine and Kaimanawa Mountains, not uncommon on cliffs, bank-sides, &c. Sea-level to 2500 ft. October–January.

A handsome species, remarkable for the broad flat leaves. When out of flower it might easily be mistaken for an iridaceous plant. Mr. Colenso's *C. gahnioides* is absolutely indistinguishable from the type.

2. **C. complanatum** *Berggr. in Minnesk. Fisiog. Sallsk. Lund.* (1877) 23, t. 6, f. 1–5.—Stems tall, rather stout, compressed and 2-edged, smooth, finely striate, 2–4 ft. high, $\frac{1}{4}$ in. diam. at the base. Leaves about the length of the stem, distichous and equitant at the base, narrow-ensiform, acuminate, flat or slightly convex, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, pale-green, smooth, striate; margins even, not scabrid. Panicle long and narrow, 6–12 in., much branched; branches fascicled, erect; bracts sheathing, with ciliate margins. Spikelets numerous, chestnut-brown, $\frac{1}{6}$–$\frac{1}{5}$ in. long, ovate-oblong, 2–3-flowered, 1 or 2 of the flowers fertile. Glumes usually 5, ovate, acuminate, striate; margins ciliate; 2 or 3 outer empty. Stamens 3. Style-branches 3. Nut almost sessile, ovoid, trigonous, puberulous, pale-chestnut, narrowed upwards into a rather stout pyramidal beak.—*Cheesem. Man. N.Z. Fl.* (1906) 785; *Ill. N.Z. Fl.* ii (1914) t. 210.

North Island: Auckland—Ohaeawai and Taheke, *Berggren!* Puhipuhi Forest, *T. Kirk!* Maungatapere, *H. Carse!* September–November.

Apparently a very local plant, not yet found outside the Bay of Islands and Whangarei Counties.

3. **C. articulatum** *R. Br. Prodr.* (1810) 237.—Stems tall and stout, terete, transversely septate, 3–6 ft. high. Leaves long, almost equalling the stems, terete, the transverse septa usually very distinct; sheaths large and long, pale; tip subulate, acute, pungent. Panicle large, lax, terminal, much branched, drooping, 9–18 in. long; branches numerous, closely placed; bracts sheathing, the lowest with a terete septate lamina $\frac{1}{2}$–$1\frac{1}{2}$ in. long. Spikelets excessively numerous, rich red-brown, $\frac{1}{6}$ in. long, 2–4-flowered, but usually only one flower is fertile. Glumes 4–7, ovate or ovate-lanceolate, acuminate, keeled, membranous, puberulous, the 2 outer empty. Stamens 3. Style-branches 3. Nut broadly obovoid, trigonous with the angles thick and corky, red-brown; beak short, umbonate.—*Hook. f. Fl. Nov. Zel.* i (1853) 276; *Handb. N.Z. Fl.* (1864) 304; *Benth. Fl. Austral.* vii (1878) 403; *Cheesem. Man. N.Z. Fl.* (1906) 786. Baumea loculata *Boeck. in Linnaea*, xxxviii (1874) 243. Gahnia articulata *F. Muell. Second Census Austral. Pl.* (1889) 216.

North Island: Margins of lakes and ponds from the North Cape to Taupo and Hawke's Bay, not uncommon. Sea-level to 1800 ft. November–January.

Also in Australia, New Caledonia, and the New Hebrides. Small states sometimes have the stems and leaves obscurely septate.

4. **C. glomeratum** *R. Br. Prodr.* (1810) 237.—Stolons creeping, clothed with pale striated scales. Stems tufted, terete and rush-like, slender, rather soft, 1–3 ft. high. Leaves few from the base of the stem, long, terete, with acute subulate tips. Panicle contracted, 3–10 in. long; lower branches distant, usually long and narrow, erect; upper closer together, shorter and broader; primary bracts large and sheathing, almost spathaceous, reddish-brown. Spikelets numerous, fascicled, red-brown, $\frac{1}{6}$–$\frac{1}{5}$ in. long, ovate-oblong, 2–3-flowered, 1 or rarely 2 of the flowers fertile. Glumes usually 5, ovate, acuminate, membranous, striated; margins ciliate; 2–3

C. rubiginosum (Sol. ex Forst. f.) Dom. 1916. 615
Domin. 1915
Bibliothec. Bot. 85 (1915) 476

outer ones empty. Stamens 3. Style-branches 3. Nut elliptic-oblong when mature, obtusely trigonous, smooth and polished, reddish or reddish-yellow; tip tumid, acute, pubescent.—*Hook. f. Fl. Nov. Zel.* i (1853) 275; *Fl. Tasm.* ii (1860); *Handb. N.Z. Fl.* (1864) 304; *Cheesem. Man. N.Z. Fl.* (1906) 786. Schoenus rubiginosus *Forst. f. Prodr.* (1786) n. 493 (*name only*). Fuirena rubiginosa *Spreng. Fl. Hal. Mant.* (1807) 29; *A. Cunn. Precur.* (1836) n. 271; *Raoul Choix* (1846) 40. Baumea rubiginosa *Boeck. in Linnaea*, xxxviii (1874) 241.

North and South Islands, Stewart Island, Chatham Islands: Swampy places, margins of lakes, &c., plentiful in the North Island, less common in the South Island. Sea-level to 2000 ft. November–January.

Best distinguished by the narrow interrupted panicle, broad spathaceous bracts, and 2–3-flowered spikelets. It extends to Australia and Tasmania, the Malay Archipelago, and northwards to China and Japan.

5. **C. Huttoni** *T. Kirk in Trans. N.Z. Inst.* ix (1877) 551.—Stems tufted, slender, terete, rather wiry, striate, 3–5 ft. high. Leaves few towards the base of the stem, long, terete, striate; tips subulate, acute. Panicle elongated, rather lax, drooping, 10–18 in. long; lower branches remote, solitary or fascicled, 3–6 in. long or more; bracts large and sheathing, membranous, acuminate. Spikelets numerous, fascicled, brown, $\frac{1}{8}$–$\frac{1}{6}$ in. long, 2–5-flowered, rarely more than 2 of the flowers fertile. Glumes 4–7, ovate, acuminate, membranous, striated; margins ciliate. Stamens 3 or rarely 2. Style-branches 3. Nut small, oblong, obtusely trigonous, smooth when mature, pale; beak very small.—*Cheesem. Man. N.Z. Fl.* (1906) 787.

North Island: Auckland—Mongonui County, in swamps near the sea, not uncommon, *H. Carse!* Whangape, Waikare, Waihi, and other lakes in the Middle Waikato, *T. Kirk! T. F. C.*; Lake Tikitapu, Lake Taupo, *T. Kirk! T. F. C.* Sea-level to 1600 ft. December–February.

Very close to *C. glomeratum*, but distinguished by the larger size, longer panicle with drooping branches, smaller many-flowered spikelets, and smaller paler nut.

6. **C. teretifolium** *R. Br. Prodr.* (1810) 237.—Stems densely tufted, terete or slightly compressed, rush-like, firm, striate, 1–3 ft. high. Leaves few at the base of the stem, long, terete except towards the sharp subulate tip, which is often obscurely 3–4-angled; sheaths rather loose. Panicle oblong, 2–6 in. long, much branched, dense; lower branches closely placed, not distant as in *C. glomeratum*; bracts short. Spikelets very numerous, fascicled, dark-brown, $\frac{1}{6}$ in. long, 1- or rarely 2-flowered, but in the latter case the upper flower is sterile. Glumes ovate, acuminate or awned, membranous, ciliate or almost glabrous, the 2 or 3 outer empty. Stamens 3. Style-branches 3. Nut very small, oblong-orbicular, not trigonous, corky, conspicuously corrugated; beak very minute, smooth.—*Hook. f. Fl. Nov. Zel.* i (1853) 276; *Handb. N.Z. Fl.* (1864) 304; *Benth. Fl. Austral.* vii (1878) 406; *Cheesem. Man. N.Z. Fl.* (1906) 787.

North Island: Abundant in swamps from the North Cape to Hawke's Bay and Taranaki. South Island: Aorere Valley, *T. Kirk!* near Westport, *W. Townson!* Hokitika, *T. Kirk!* Franz Josef Glaćier, *Cockayne!* Canterbury, *J. B. Armstrong!* Southern Alps, *Sinclair* and *Haast* (Handbook). Sea-level to 2000 ft. November–January.

This has the habit and general appearance of *C. glomeratum*, but the stems and leaves are firmer, the panicle shorter and much more dense, bracts smaller, spikelets usually 1-flowered, and nut very different. It is also found in eastern Australia and Tasmania.

also see Blake 1943.
c. tenax (Hk.f.) Bruce 1916 : 615.

7. **C. Gunnii** *Hook. f. Fl. Tasm.* ii (1860) 95, t. 148B.—Stems densely tufted, rush-like, very slender, terete, rigid and wiry, 9 in. to 3 ft. high. Leaves sometimes wholly reduced to sheathing scales at the base of the stem, but usually 1 long terete stem-like leaf with 2–3 sheaths below it; tip subulate, pungent; sheaths long, purplish-red. Panicle elongate, narrow, interrupted, 6–18 in. long; branches remote, slender, erect, the lowest sometimes 6 in. long in large specimens, in small ones reduced to 1 in.; bracts closely sheathing, with a short erect lamina. Spikelets not fascicled, distinct, sessile, 1-flowered. Glumes usually 3, lanceolate, acuminate, the 2 lowest empty; the uppermost fertile, longer and narrower than the others, and spreading in fruit; margins involute. Stamens 3. Style-branches 3. Nut pedicelled, ovoid or oblong-ovoid, smooth and shining when mature, 3-ribbed when young, tip large and tumid, pale-yellow with dark base and tip.—*Hook. f. Handb. N.Z. Fl.* (1864) 304; *Benth. Fl. Austral.* vii (1878) 407; *Berggr. in Minnesk. Fisiog. Sallsk. Lund.* (1877) 24, t. 6, f. 6–11; *Cheesem. Man. N.Z. Fl.* (1906) 788. C. laxiflorum *Hook. f. Fl. Tasm.* ii (1860) 95, t. 148A. Lampocarya tenax *Hook. f. Fl. Nov. Zel.* i (1853) 277.

North and South Islands, Stewart Island: From the North Cape southwards, not uncommon. Sea-level to 2500 ft. December–February.

Also in eastern Australia and Tasmania. In fruit the margins of the upper part of the flowering glume become strongly involute, firmly enclosing the 3 persistent stamens, which remain attached to the pedicel of the ripe nut. The nut is thus frequently detained swinging from the spikelet long after it has separated from the point of attachment.

8. **C. junceum** *R. Br. Prodr.* (1810) 237.—Rhizome stout, woody, creeping, clothed with pale-brown scales. Stems tufted, rigid, erect, terete, rush-like, 1–2 ft. high. Leaves reduced to 1 long and closely appressed sheath with a minute vertically flattened lamina, below which are 1 or 2 much shorter sheaths. Panicle short, spike-like, sparingly branched, ½–1½ in. long; bract at the base very small. Spikelets red-brown, ⅛ in. long, 1–2-flowered, the lower flower alone fertile. Glumes 4–5, oblong-ovate, acute, membranous, keeled, puberulous, the 2 or 3 outer empty. Stamens 3. Style-branches 3. Nut oblong-ovoid, obscurely trigonous, dark-brown, surface rough; beak small, tumid, puberulous.—*Hook. f. Fl. Tasm.* ii (1860) 95; *Handb. N.Z. Fl.* (1864) 305; *Benth. Fl. Austral.* vii (1878) 408; *Cheesem. Man. N.Z. Fl.* (1906) 788. Lepidosperma striatum *Hook. f. Fl. Nov. Zel.* i (1853) 279 (*not of R. Br.*). L. Colensoi *Boeck. in Linnaea*, xxxviii (1874) 328. Schoenus marginiculatus Soland. m.s. p.61.

Var. **elatior** *H. Carse in Trans. N.Z. Inst.* xlviii (1916) 240.—Culms much longer, 3–5 ft. high. Panicles 2–4 in. long, much more branched than in the type. In shaded woods at Tauroa, Mongonui County, *H. Carse!*

North and South Islands: From the North Cape to the Bluff, not uncommon, especially in the North Island, often in brackish-water swamps. Sea-level to 2000 ft. November–January.

Also throughout the greater part of Australia and in New Caledonia.

c. australe (a. Rich) Bruce 1916 : 615

9. **C. Vauthiera** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 788.—Rhizome short, stout, creeping. Stems densely tufted, rather stout, conspicuously 4-angled, smooth, wiry, rigid, 9–18 in. high. Leaves 1 or 2 like the stems, 2–10 in. long, sometimes reduced to sheathing scales. Panicle contracted into a dense oblong spike-like head ⅓–½ in. long, subtended by a

Vauthiera

rigid sheathing bract terminated by a subulate erect point. Spikelets few, densely compacted, $\frac{1}{6}$ in. long, 1-flowered. Glumes 5–6, ovate-lanceolate, acute or acuminate, coriaceous, puberulous, the terminal one subtending the flower, the remainder all empty. Hypogynous scales 6, small, white, triangular, connate into a 6-lobed cup. Stamens 3. Style-branches 3. Nut broadly oblong, obtusely trigonous, smooth, red-brown; beak short, ovoid-conic, pubescent.—Vauthiera australis *A. Rich. Fl. Nouv. Zel.* (1832) 107, t. 20; *A. Cunn. Precur.* (1836) n. 276; *Raoul Choix* (1846) 40. Lepidosperma australe *Hook. f. Fl. Nov. Zel.* i (1853) 279. L. tetragonum *Hook. f. Handb. N.Z. Fl.* (1864) 307 (*not of Labill.*).

North and South Islands, Stewart Island: Not uncommon throughout. Sea-level to 2000 ft. November–January.

This differs from *Lepidosperma*, to which it was referred by Hooker, in always wanting the sterile flower below the fruit-bearing one. I have followed Mr. Clarke's suggestion in placing it in *Cladium*, notwithstanding the presence of hypogynous bristles. It is endemic in New Zealand.

10. **C. capillaceum**, *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 789.—Rhizome short, creeping. Stems densely tufted, very slender, filiform, wiry, terete, finely striate, 9–18 in. high. Leaves reduced to a single closely appressed purplish-red sheath, usually with a very minute erect scale-like lamina at the tip. Panicle terminal, very small, slender, $\frac{1}{2}$–$\frac{3}{4}$ in. long, of from 3 to 7 spikelets. Spikelets narrow, obscurely distichous, $\frac{1}{8}$–$\frac{1}{6}$ in. long, 1-flowered. Glumes usually 5, ovate-lanceolate, awned, membranous, the 3 outer empty. Stamens 3. Style-branches 3. Nut oblong-ovoid, 3-ribbed, pale, smooth, crowned by the long and narrow pubescent style-base, which is as long as the nut itself.—Chaetospora capillacea *Hook. f. Fl. Tasm.* ii (1860) 81, t. 141A (*not of Nees*). C. capillaris *F. Muell. Fragm. Phyt. Austral.* ix (1875) 34. Elynanthus capillaceus *Benth. Fl. Austral.* vii (1878) 377. Schoenus capillaris *F. Muell. Second Census Austral. Pl.* (1889) 215. S. tenuis *T. Kirk in Trans. N.Z. Inst.* i, ed. ii (1871) 94.

North Island: From the North Cape southwards, not uncommon. South Island: Near Westport, *W. Townson!* Sea-level to 2000 ft. December–February.

Also found in Victoria and Tasmania. The narrow elongated persistent style-base gives the nut a different appearance to that of any other New Zealand species.

10. **LEPIDOSPERMA** Labill.

Perennial herbs. Stems stout, leafy at the base, often flat or compressed. Leaves similar to the stems, sheathing at the base. Inflorescence a terminal panicle, either long and much branched, or short and spike-like. Spikelets numerous, 2–4-flowered, the uppermost flower perfect and fruit-bearing, the remainder sterile. Glumes 5–10, subdistichous, imbricate; outer 1–6 empty. Hypogynous bristles 6, short, ovate or lanceolate with a setiform tip. Stamens 3. Style-branches 3. Nut ovoid or oblong, obtusely trigonous; tip obtuse, indurated, smooth.

Species 40. One of them is endemic in South China and Malacca, the remaining 35 are confined to Australia, with the exception of two which are found in New Zealand as well.

Stems flat and thin. Panicle narrow, lax, 4–12 in. long	1. *L. laterale.*
Stems slender, terete. Spike simple, 1–3 in. long	2. *L. filiforme.*

1. **L. laterale** *R. Br. Prodr.* (1810) 234. — Stems densely tufted, flat or very slightly convex, with sharp almost cutting edges, smooth, firm, 2–4 ft. high, $\frac{1}{5}$–$\frac{1}{4}$ in. broad. Leaves 3–5, similar to the stems but shorter, equitant at the base. Panicle long and narrow, 4–12 in. long; branches not very closely placed, elongated, erect, simple or again branched, lowest bract with an erect lamina $1\frac{1}{2}$–4 in. long, upper bracts short. Spikelets sessile, red-brown, $\frac{1}{5}$ in. long, usually with 1 perfect flower and 1 sterile one below it. Glumes ovate, acuminate or almost awned, keeled, minutely puberulous on the back, the 3 outer empty. Hypogynous bristles 6, connate at the base, small, short, tipped with delicate fragile setae which are sometimes $\frac{1}{2}$ as long as the nut. Stamens 3. Style-branches 3. Nut ovoid-oblong, obtusely trigonous, smooth when fully mature, tip tumid.—*Benth. Fl. Austral.* vii (1878) 393; *Cheesem. Man. N.Z. Fl.* (1906) 790. L. concavum *Hook. f. Fl. Tasm.* ii (1860) 91, t. 146B; *Handb. N.Z. Fl.* (1864) 307 (*not of R. Br.*). L. longitudinalis *Hook. f. Fl. Nov. Zel.* i (1853) 279 (*not of Labill.*).

North Island: Auckland—Clay hills from the North Cape to the Upper Waikato, not uncommon. Sea-level to 1500 ft. January–February.

Also in eastern Australia and Tasmania.

2. **L. filiforme** *Labill. Pl. Nov. Holl.* i (1806) 17, t. 15. — Rhizome short, stout, woody, creeping. Stems numerous, densely tufted, slender but rigid, erect, terete, rush-like, 1–3 ft. high. Leaves reduced to a rather long and closely appressed sheath, terminating in a short and almost filiform erect lamina. Spike simple, terminal, 1–3 in. long; rhachis slender, straight or scarcely flexuose; sheathing bracts narrow. Spikelets 1 to each bract, narrow-linear, terete or nearly so, $\frac{1}{3}$ in. long, 2-flowered, the upper flower perfect, the lower sterile. Glumes 4–5, narrow-lanceolate, acute, the 2 or 3 outer ones shorter and broader, empty. Stamens 3. Nut oblong, obtuse or minutely apiculate, obtusely trigonous with a thickened line down the angles. Hypogynous scales at the base of the nut minute, whitish, subulate-lanceolate, acute, closely appressed.—*Hook. f. Fl. Tasm.* ii (1860) 93 (*in part*); *F. Muell. Fragm. Phyt. Austral.* ix (1875) 27; *Benth. Fl. Austral.* vii (1878) 399; *Cheesem. Man. N.Z. Fl.* (1906) 790.

North Island: Auckland—Clay hills between Mangonui and Kaitaia, and near Rangaunu Harbour, *H. Carse!* August–September.

I am indebted to Mr. C. B. Clarke for identifying this with the Australian *L. filiforme*. So far, it has only been gathered in New Zealand by Mr. Carse, but it will probably prove to be not uncommon north of Auckland. In Australia it has been recorded from Victoria and Tasmania.

11. GAHNIA Forst. 1776

Tufted perennial herbs, usually of large size. Stems tall and stout, leafy throughout their length. Leaves usually long, very coarse and harsh, narrowed into long subulate or filiform points; margins involute, scabrid. Panicle large, terminal; sometimes broad and effuse, with drooping branches; sometimes narrower and more erect. Spikelets clustered, black or dark-brown, 1–2-flowered; the upper flower hermaphrodite and fruit-bearing; the lower flower sterile or male. Glumes many, imbricated all round; the outer 2–5 or more empty, keeled, often mucronate; flowering glumes minute at first, but enlarging in fruit. Hypogynous bristles wanting. Stamens usually 4 in the hermaphrodite

1. **G. setifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 278.—Stems numerous, tall, stout, 3–7 ft. high, forming large tussocks. Leaves many, almost as long as the stems, involute, with scabrid cutting edges and long filiform points. Panicle large, nodding, 1–3 ft. long, much and laxly branched; branches long, erect in flower, drooping in fruit; bracts long and leafy, with scabrid filiform points. Spikelets very numerous, dark-brown or almost black, $\frac{1}{6}$–$\frac{1}{5}$ in. long, 2-flowered; the lower flower male, the upper hermaphrodite and fruit-bearing. Glumes 7–8; the 4–5 outer ones empty, gradually increasing in length, keeled, acuminate, minutely scaberulous; the 3 upper very small at the time of flowering and concealed within the uppermost empty glume, enlarged in fruit and closely appressed to the nut, obtuse, convolute. Stamens usually 4 to each flower, but varying from 4 to 6; filaments greatly elongated in fruit. Style-branches 3, rarely 4. Nut small, $\frac{1}{6}$ in. long, elliptic-obovoid, narrowed at both ends, smooth and shining, indistinctly grooved, red-brown when fully ripe, transversely grooved within.—*Hook. f. Handb. N.Z. Fl.* (1860) 306; *Cheesem. Man. N.Z. Fl.* (1906) 792; *C. B. Clarke Ill. Cyp.* (1909) t. xcviii, f. 1–7. G. scaberula, G. parviflora, *and* G. multiglumis *Col. in Trans.*

long and closely appressed sheath, terminating in a short and almost filiform erect lamina. Spike simple, terminal, 1–3 in. long; rhachis slender, straight or scarcely flexuose; sheathing bracts narrow. Spikelets 1 to each bract, narrow-linear, terete or nearly so, $\frac{1}{3}$ in. long, 2-flowered, the upper flower perfect, the lower sterile. Glumes 4–5, narrow-lanceolate, acute, the 2 or 3 outer ones shorter and broader, empty. Stamens 3. Nut oblong, obtuse or minutely apiculate, obtusely trigonous with a thickened line down the angles. Hypogynous scales at the base of the nut minute, whitish, subulate-lanceolate, acute, closely appressed.—*Hook. f. Fl. Tasm.* ii (1860) 93 (*in part*); *F. Muell. Fragm. Phyt. Austral.* ix (1875) 27; *Benth. Fl. Austral.* vii (1878) 399; *Cheesem. Man. N.Z. Fl.* (1906) 790.

North Island: Auckland—Clay hills between Mangonui and Kaitaia, and near Rangaunu Harbour, *H. Carse!* August–September.

I am indebted to Mr. C. B. Clarke for identifying this with the Australian *L. filiforme*. So far, it has only been gathered in New Zealand by Mr. Carse, but it will probably prove to be not uncommon north of Auckland. In Australia it has been recorded from Victoria and Tasmania.

11. GAHNIA Forst. 1776

Tufted perennial herbs, usually of large size. Stems tall and stout, leafy throughout their length. Leaves usually long, very coarse and harsh, narrowed into long subulate or filiform points; margins involute, scabrid. Panicle large, terminal; sometimes broad and effuse, with drooping branches; sometimes narrower and more erect. Spikelets clustered, black or dark-brown, 1–2-flowered; the upper flower hermaphrodite and fruit-bearing; the lower flower sterile or male. Glumes many, imbricated all round; the outer 2–5 or more empty, keeled, often mucronate; flowering glumes minute at first, but enlarging in fruit. Hypogynous bristles wanting. Stamens usually 4 in the hermaphrodite

flower, often 4–6 in the male flower; filaments greatly elongated after flowering, and often holding the nut. Nut hard and bony, ellipsoid or ovoid or obovoid, obscurely trigonous or terete, red or reddish-brown or black.

Species about 35, most of them natives of Australia and New Zealand, but extending through the Pacific islands to the Sandwich Islands and Malay Archipelago. Of the 8 found in New Zealand, one occurs in Lord Howe Island and another in the Sandwich Islands, the remaining 6 are endemic. The genus is remarkable for the extraordinary extent to which the filaments lengthen after flowering. In *G. procera* they are often quite 2 in. long, or from 8 to 10 times the length of the flowering glumes. They generally remain attached to the base of the nut after it has fallen away, and as the other end of the filament is usually entangled with the glumes or with the filaments of other flowers the nut remains swinging by the filaments quite free from the spikelet. Mr. Colenso (Trans. N.Z. Inst. xviii (1886) 281) has suggested that some of these filaments are in reality hypogynous scales, giving as a reason for this belief that in his *G. scaberula* and *G. exigua* he has noticed within the same flower stamens with the filaments still very short, and filaments already lengthened to the full extent. He failed to notice that the lower male flower expands long before the hermaphrodite flower placed just above it, so that its filaments have lost their anthers and lengthened long before the expansion of the upper flower takes place. The two flowers are placed so close together that it is quite easy to take the two for one.

Tall, 3–7 ft. Panicle 1–3 ft., nodding. Glumes 7–8; 4–5 empty, unequal. Nut small, $\frac{1}{6}$ in., red-brown	1. *G. setifolia.*
Smaller, 2–4 ft. Panicle 1½–2½ ft., rigid, erect. Glumes 6–7; 3–4 empty, subequal. Nut small, $\frac{1}{6}$ in., red-brown	2. *G. rigida.*
Slender, 2–4 ft. Panicle 1½–2½ ft., narrow, elongate, branches distant. Glumes 8; 5 empty, unequal. Fruit large, $\frac{1}{5}$–$\frac{1}{4}$ in., red-brown	3. *G. pauciflora.*
Very tall and stout, 5–12 ft. Panicle 2–5 ft., nodding. Glumes 6–7; 4–5 empty, subequal. Nut large, $\frac{1}{5}$–$\frac{1}{4}$ in., black when fully ripe	4. *G. xanthocarpa.*
Tall and stout, 5–7 ft. Panicle 2–3 ft., rigid, erect. Glumes 8; 5 empty, subequal. Nut small, $\frac{1}{6}$ in., black	5. *G. robusta.*
Leafy, 2–4 ft. Panicle 1–1½ ft., narrow, lax. Glumes 4; 2 empty, very long. Nut large, $\frac{1}{4}$ in., red-brown	6. *G. procera.*
Slender, 2–4 ft. Panicle 9–18 in., slender, narrow but dense. Glumes 4–5; 2–3 empty. Nut small, $\frac{1}{6}$ in., black	7. *G. lacera.*
Small, 6–14 in. Leaves exceeding the stem, spreading. Glumes 6; 4 empty. Nut small, ovoid, apiculate, black	8. *G. gahniaeformis.*

1. **G. setifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 278.—Stems numerous, tall, stout, 3–7 ft. high, forming large tussocks. Leaves many, almost as long as the stems, involute, with scabrid cutting edges and long filiform points. Panicle large, nodding, 1–3 ft. long, much and laxly branched; branches long, erect in flower, drooping in fruit; bracts long and leafy, with scabrid filiform points. Spikelets very numerous, dark-brown or almost black, $\frac{1}{6}$–$\frac{1}{5}$ in. long, 2-flowered; the lower flower male, the upper hermaphrodite and fruit-bearing. Glumes 7–8; the 4–5 outer ones empty, gradually increasing in length, keeled, acuminate, minutely scaberulous; the 3 upper very small at the time of flowering and concealed within the uppermost empty glume, enlarged in fruit and closely appressed to the nut, obtuse, convolute. Stamens usually 4 to each flower, but varying from 4 to 6; filaments greatly elongated in fruit. Style-branches 3, rarely 4. Nut small, $\frac{1}{6}$ in. long, elliptic-obovoid, narrowed at both ends, smooth and shining, indistinctly grooved, red-brown when fully ripe, transversely grooved within.—*Hook. f. Handb. N.Z. Fl.* (1860) 306; *Cheesem. Man. N.Z. Fl.* (1906) 792; *C. B. Clarke Ill. Cyp.* (1909) t. xcviii, f. 1–7. G. scaberula, G. parviflora, *and* G. multiglumis *Col. in Trans.*

N.Z. Inst. xviii (1886) 278–80. Lampocarya setifolia *A. Rich. Fl. Nouv. Zel.* (1832) 111; *A. Cunn. Precur.* (1836) n. 282; *Raoul Choix* (1846) 40.

North Island: Abundant throughout, mainly in light forest or scrub. South Island: Marlborough—Picton, *J. Rutland!* Sea-level to 2000 ft. December–January.

2. **G. rigida** *T. Kirk in Trans. N.Z. Inst.* ix (1877) 551.—Stems densely tufted, harsh and rigid, erect, 2–4 ft. high. Leaves equalling the stems, with involute scabrid margins and very long drooping filiform points. Panicle stiff, erect, rather narrow, elongate, 1½–2½ ft. long; branches numerous, short, strict, erect; bracts with dark sheaths and long filiform points. Spikelets numerous, crowded, dark-brown or almost black, ⅕–¼ in. long, 2-flowered; the lower flower male, the upper hermaphrodite and fruit-bearing. Glumes 6–7; the 3–4 outer empty, almost equal in length, keeled, narrowed into long acuminate points, scaberulous on the keel, margins paler, membranous; the 3 inner small at the time of flowering, enlarged in fruit, convolute, obtuse. Stamens 4–5 in each flower; filaments greatly elongated in fruit. Style-branches 3. Nut small, ⅙ in. long, oblong-obovoid, smooth, brown, or brown mottled with red and black.—G. exigua *Col. in Trans. N.Z. Inst.* xviii (1886) 279.—*Cheesem. Man. N.Z. Fl.* (1906) 792.

South Island: Nelson—Dun Mountain, *T. F. C.;* Aorere Valley and Ngakawau, *T. Kirk;* Westport, *W. Townson!* Westland—Between Hokitika and Ross, Marsden, near Greymouth, *T. Kirk!* southwards to the Waiho River and the Franz Josef Glacier, *Cockayne.* Sea-level to 2500 ft.

Distinguished from *G. setifolia* by the usually smaller size, erect rigid panicle, longer and more acuminate subequal glumes, and more obovoid nut. The erect compact panicle, subequal glumes, and small nut separate it from the following species.

3. **G. pauciflora** *T. Kirk in Trans. N.Z. Inst.* i, ed. 2 (1871) 94.—Stems slender, sparingly leafy, 2–3 ft. high, rarely more. Leaves equalling the stems, narrow, with scabrid cutting edges and long filiform points. Panicle long, lax but narrow, 1½–3 ft. long; branches distant, slender; bracts long, leafy. Spikelets loosely scattered on the branches of the panicle, not crowded, sessile or shortly pedicelled, brownish-black, ⅕–¼ in. long, 2-flowered; lower flower male, upper hermaphrodite and fruit-bearing. Glumes usually 8; the 5 lower ones empty, gradually increasing in size, ovate, acute or acuminate; the 3 upper small at first, but enlarging in fruit, deeply concave, appressed to the nut, obtuse. Stamens 4–5 to each flower; filaments greatly elongated in fruit. Style-branches 3–4. Nut large, ⅕–¼ in. long, elliptic-ovoid, acute at both ends, smooth and shining, often grooved on the inner face, red-brown with a dark tip, transversely grooved within.—*Cheesem. Man. N.Z. Fl.* (1906) 793; *C. B. Clarke Ill. Cyp.* (1909) t. xcvii, f. 6. G. Hectori *T. Kirk in Trans. N.Z. Inst.* ix (1877) 551.

North and South Islands: From the North Cape southwards to Marlborough, Nelson, and Westland, plentiful. Sea-level to 3000 ft. October–December.

A well-marked species, at once recognized by the slender elongated panicle, with lax distant branches; the numerous empty glumes, the lower of which are unusually small; and the large red-brown nut.

4. **G. xanthocarpa** *Hook. f. Handb. N.Z. Fl.* (1864) 306.—Stems numerous, stout, often as thick as the finger, densely tufted, leafy, 5–12 ft. high, forming huge clumps in forests. Leaves numerous, very long, ½ in. broad or more, involute, scabrid on the margins and veins, upper part

produced into long filiform points. Panicle very large, 2–5 ft. long, drooping, excessively branched; branches long, slender, pendulous, 9–18 in. long or even more; bracts long, leafy. Spikelets innumerable, densely crowded, brown, $\frac{1}{5}$–$\frac{1}{4}$ in. long, 2-flowered; lower flower male, upper flower hermaphrodite and fruit-bearing. Glumes 6–7; the 3–4 outer empty, not very different in length, ovate, shortly acuminate; the 3 upper smaller, deeply concave, obtuse. Stamens usually 4 to each flower; filaments lengthening much in fruit. Style-branches 3–4. Nut large, $\frac{1}{5}$–$\frac{1}{4}$ in. long, elliptic-oblong or -obovoid, acute at both ends, smooth and shining, sometimes indistinctly grooved, black when fully ripe, yellowish when immature, transversely grooved within.—*Benth. Fl. Austral.* vii (1878) 418; *Cheesem. Man. N.Z. Fl.* (1906) 793. G. ebenocarpa *Hook. f. ex T. Kirk in Trans. N.Z. Inst.* i (1869) 149. Lampocarya xanthocarpa *Hook. f. Fl. Nov. Zel.* i (1853) 278. Cladium xanthocarpum *F. Muell. Fragm. Phyt. Austral.* ix (1875) 13.

North Island: Not uncommon in forests throughout. South Island: Marlborough—*J. Rutland!* Nelson—Motueka Valley, *T. F. C.*; Westport, *W. Townson!* Westland—Hokitika, *T. Kirk!* Martin's Bay, *Poppelwell* and *Thomson!* Canterbury—*Haast, J. B. Armstrong.* Sea-level to 2500 ft. February–March.

The finest species of the genus, at once identified by its large size, enormous panicles, and large black nut. It forms a marked constituent of almost all forest districts in the North Island, particularly in the kauri forests, and also extends along the west coast of the South Island as far as Martin's Bay. It is apparently not uncommon in Lord Howe Island.

5. **G. robusta** *T. Kirk in Trans. N.Z. Inst.* xxvi (1894) 261.—Stems robust, as thick as the little finger, 6–7 ft. high. Leaves almost as long as the stems, involute, with scabrid margins and long filiform points. Panicle large, 2–3 ft. long, dense, narrow, erect; branches 5–10 in. long, strict, erect; bracts leafy, with long filiform points. Spikelets crowded, dark-brown or almost black, 2-flowered; lower flower male, upper hermaphrodite and fruit-bearing. Glumes usually 7; the 4 outer empty, subequal, awned; the 3 inner small in the flowering stage, but enlarged in fruit, concave, coriaceous, obtuse. Stamens 4–6 in each flower, elongated in fruit. Style-branches 2–4. Nut small, $\frac{1}{6}$–$\frac{1}{5}$ in. long, elliptic-obovoid, black when fully ripe, transversely grooved within.—*Cheesem. Man. N.Z. Fl.* (1906) 794.

North Island: Wellington—Mungaroa, *T. Kirk!* March.

My knowledge of this plant is confined to the specimens in Mr. Kirk's herbarium. These greatly resemble *G. rigida*, but the plant is said to be much larger, and the nut to be always black when fully ripe.

6. **G. procera** *Forst. Char. Gen.* (1776) 52.—Stems stout, densely tufted, 2–4 ft. high. Leaves equalling or exceeding the stems, narrowed into long filiform points; margins involute, smooth below, scabrid above; sheaths dark-brown or almost black. Panicle slender, lax but narrow, elongate, 12–18 in. long; branches often remote, short, erect or slightly drooping in fruit; bracts leafy, with purplish-black sheaths. Spikelets scattered along the branches or clustered towards their tips, large, $\frac{1}{3}$–$\frac{1}{2}$ in. long, dark purplish-black, 2-flowered; lower flower male, upper hermaphrodite and fruit-bearing. Glumes 4; 2 outer empty, very large and exceeding the spikelet, elliptic-lanceolate, mucronate, striate; 2 inner shorter, oblong-lanceolate, obtuse. Stamens usually 4 to each flower; filaments elongating greatly in fruit. Style-branches 4. Nut large, $\frac{1}{4}$ in. long, narrow-elliptic, smooth and shining, obscurely grooved, reddish-brown or reddish-yellow when ripe, transversely grooved within.—*A. Rich. Fl.*

Nouv. Zel. (1832) 112; *A. Cunn. Precur.* (1836) n. 284; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 278; *Handb. N.Z. Fl.* (1864) 306; *Cheesem. Man. N.Z. Fl.* (1906) 306; *Ill. N.Z. Fl.* ii (1914) t. 212.

South Island: Probably abundant on the western side of the Island. Nelson—Buller Valley, *T. F. C.*; Mount Rochfort and vicinity of Westport, *W. Townson!* Westland—Hokitika, *T. Kirk!* Kelly's Hill, *Cockayne!* Otago—Dusky Sound, *Forster*; Port Preservation, *Lyall*; Clinton Valley, *Petrie.* Stewart Island: Port Pegasus, *Petrie! Pearson!* Sea-level to 2500 ft. December–February.

A very distinct species, remarkable for the large purplish-black spikelets and long empty glumes, which are only two in number. There is an unnamed specimen, presumably from the North Island, in Mr. Colenso's herbarium.

7. **G. lacera** *Steud. Cyp.* (1855) 164.—Stems rather slender, leafy, densely tufted, 2–4 ft. high. Leaves equalling or exceeding the stems, flat or involute, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, narrowed into long filiform points, margins scabrid. Panicle elongated, narrow but rather dense, 9–18 in. long; branches short, erect or inclined; bracts long and leafy. Spikelets alternate on the branches of the panicle, shortly pedicelled, brown, 1-flowered. Glumes 4–5; 2 or 3 outer empty, subequal, ovate or ovate-lanceolate, acuminate or awned, rather membranous, minutely scaberulous on the back; 2 inner shorter, concave, obtuse, margins scarious and lacerate. Stamens 4; filaments greatly elongate in fruit. Style-branches 3. Nut small, $\frac{1}{6}$ in. long, oblong-obovoid, obtuse, shining, black, very obscurely transversely striate within.—*Hook. f. Handb. N.Z. Fl.* (1864) 306; *Cheesem. Man. N.Z. Fl.* (1906) 795. Lampocarya lacera *A. Rich. Fl. Nouv. Zel.* (1832) 109; *A. Cunn. Precur.* (1836) n. 281; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 277.

North Island: From the North Cape to Cook Strait, not uncommon. Sea-level to 2000 ft. July–August.

This is quoted from the South Island in the Handbook, but I have seen no specimens from thence.

8. **G. gahniaeformis** *A. A. Heller in Minnes. Bot. Stud.* i, 802.—Stems short, densely tufted, obtusely trigonous, leafy, 6–18 in. high. Leaves very numerous, spreading, much exceeding the stems, narrow, rigid, scabrid, sheaths short, submembranous. Panicle narrow, contracted, rigid, leafy, 3–9 in. long; branches few, short, erect; bracts very long and leafy. Spikelets clustered on the branches, elliptic-lanceolate, turgid, acute, chestnut-brown, 1-flowered. Glumes 6, firm and coriaceous, minutely puberulous, ciliolate on the margins; 4 outer small, gradually increasing in size, ovate-lanceolate, acuminate, awned; 2 inner much longer, rigid in fruit, acuminate. Stamens usually 3; filaments scarcely lengthening after flowering. Style-branches 3. Nut small, ovoid, obscurely trigonous, minutely apiculate, smooth, black, not transversely grooved within.—G. Gaudichaudii *Steud. Cyp.* (1855) 164; *Hillebr. Fl. Hawaii* (1888) 481; *Cheesem. Man. N.Z. Fl.* (1906) 795; *C. B. Clarke Ill. Cyp.* (1909) t. xciii, f. 5–6. G. affinis *Steud. Cyp.* (1855) 164. G. arenaria *Hook. f. Handb. N.Z. Fl.* (1864) 306. Lampocarya affinis *Brong. in Duperr. Voy. Coq. Bot.* (1829) 166, t. 29; *Hook. f. Fl. Nov. Zel.* i (1853) 277. Morelotia gahniaeformis *Gaud. in Freyc. Voy. Bot.* (1826) 416, t. 28; *A. Rich. Fl. Nouv. Zel.* (1832) 115; *A. Cunn. Precur.* (1836) n. 285; *Raoul Choix* (1846) 40.

North and South Islands: Dry hills from the North Cape to Banks Peninsula, but not common to the south of Cook Strait. Sea-level to 2000 ft.

Also in the Sandwich Islands.

Var. strictus (Berggr.) H. Pfeiffer.Syn.O. strictus Berggr., O. serrulatus Col. Neu-Seeland, Mt Tongariro, H. Hill.

(Pfeiffer calls O. pumilio "planta maxime variabilis"; the difference between it and var. strictus are, acc. to him: strictus nuce oblonga apice acutata, alba, granulis poriferis dense obtecta; pumilio nuce obovata obtusa subtrigona nitida. - C.S. has a strong feeling that P:s work is humbug.)

p. 352. O. Pfeifferianus Barros.-Herbula muscoidea caespitosa glabra; caulibus erectis 4-10 cm altis subfastigiatis superne ramosis dense foliosis, ramis sparsis apice 1-floris; foliis 3-8 cm longis erectis undique arcte imbricatis lineari-subulatis obtusis tere-tiusculis compressis fistulosis basi vaginantibus, dorso versus medium vaginibusque vaginarum parce ciliatis; pedunculis brevissimis flores ♀ 1 (staminaque 3)gerentibus; nuce exacte globulata quam in O. Pumilio brevior, styli basi permanente rostellulata. Australien. N.S.Wales (Wilcox!).

What you, Lucy May Cranwell, should do get togethe living, flowering and fruiting material of all N.Z. Oreobolus, monograph them proprly morphologically and anatomic-ally, for this has never been made: and the confusim will disappear. There may be hybrids when they grow mixed, as they certainly do.- I do not know who Barros is; Ind. Kew. quotes "Barros in Fedde, Repert."

12. OREOBOLUS R. Br. 1810

Dwarf perennial herbs, forming dense cushion-shaped masses in alpine bogs. Stems branched, very closely compacted, leafy throughout. Leaves numerous, close-set, distichous and equitant, more rarely irregularly imbricate all round. Peduncle axillary, short at first but lengthening after the flowers expand, strict, compressed, bearing a terminal spikelet with or without 1 or 2 lateral ones. Spikelets minute, narrow, 1-flowered; flower hermaphrodite. Glumes 3 or rarely 4, the outer the largest, the second and third subequal, the fourth when present small, not much longer than the nut. Hypogynous scales (perianth-segments) 6, in 2 series, subequal, narrow, rigid, erect. Stamens 3. Style slender, continuous with the ovary; branches 3. Nut obovoid, obtuse with a depressed star-like mark at the apex, smooth.

In addition to the 3 species described below, one of which extends to Victoria and Tasmania, there is also one in Andine and antarctic America, and another in the Sandwich Islands.

Leaves obscurely distichous, very narrow, strict. Peduncle shorter than the leaves; spikelets usually 1 .. .. 1. *O. strictus.*
Leaves obscurely distichous. Peduncle shorter than the leaves; spikelets usually 2, rarely 1 or 3 .. .. 2. *O. pumilio.*
Leaves conspicuously distichous. Peduncles often equalling or exceeding the leaves in fruit; spikelets usually 1 .. .. .. 3. *O. pectinatus.*

1. **O. strictus** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 25, t. 6, f. 12–24.—Stems 2–3 in. high, creeping and rooting at the base, laxly tufted, much branched; branches not nearly so dense as in *O. pumilio*, erect, curved, leafy throughout their length. Leaves obscurely distichous, 1–2½ in. long, strict and erect or secund, very narrow-linear, deeply canaliculate above, obtuse, margins minutely serrulate; sheaths broad, membranous, 3–5-nerved, rounded or truncate at the tip. Peduncle much shorter than the leaves; spikelets 1, rarely 2, narrow. Glumes 3; outer the largest, minutely serrulate; the two others subequal, narrow, erect. Hypogynous scales 6, narrow-lanceolate, acute, minutely serrulate. Stamens 3. Style-branches 3, long, filiform. Nut small, obovoid, narrowed at the base, obtuse, white.—*Cheesem. Man. N.Z. Fl.* (1906) 797. O. serrulatus *Col. in Trans. N.Z. Inst.* xxii (1890) 492.

North Island: Rangipo Plain, Ruapehu, *H. Hill;* Ruahine Mountains, *B. C. Aston!* South Island: Nelson—Mount Arthur Plateau, *T. F. C.;* Lake Rotoiti, *T. Kirk!* Canterbury—Arthur's Pass, *Berggren! T. Kirk! T. F. C.;* Lake Tennyson, *R. M. Laing.* Westland—Mount Greenland, *Cockayne.* Otago—Not uncommon on the mountains of the interior, *T. Kirk! Petrie!* and others. Stewart Island: Fairly plentiful, *T. Kirk! Cockayne.* Usually between 3000 and 5000 ft., but descends to sea-level in Stewart Island and the south of Otago.

Very close to *O. pumilio*, but a much more laxly tufted plant, with narrower strict leaves, which considerably overtop the peduncle.

2. **O. pumilio** *R. Br. Prodr.* (1810) 236. — Stems much branched, short, ½–2 in. high, forming broad and dense cushion-shaped masses. Leaves obscurely distichous, ½–1½ in. long, erect or incurved, rarely spreading, narrow-linear, narrowed towards the obtuse tip, concave or almost flat in front, veinless or indistinctly 3-nerved; margins minutely serrulate; sheaths equitant, membranous, 3-nerved. Peduncles stout, rigid, mostly shorter than the leaves; spikelets usually 2, rarely 3 or 1. Glumes 3–4; the outer one the largest, leaf-like, 3-nerved; the second and third about

equal; the fourth, when present, minute, not much exceeding the nut. Hypogynous scales narrow-lanceolate, acute, serrulate. Stamens 3. Style-branches 3. Nut small, obovoid, obtuse, whitish or brownish.—*Hook. f. Handbk. N.Z. Fl.* (1864) 308; *Fl. Tasm.* ii (1860) 94; *Benth. Fl. Austral.* vii (1878) 346; *Cheesem. Man. N.Z. Fl.* (1906) 796; *C. B. Clarke Ill. Cyp.* (1909) t. cii, f. 1–5.

South Island: Nelson—Mount Rochfort and other mountains near Westport, *W. Townson!* Westland—Arthur's Pass, *T. F. C.;* Kelly's Hill, *Petrie!* Worsley's Pass, *Cockayne!* Otago—Mountains above Lake Harris, *T. Kirk!* 2000–5000 ft.

3. **O. pectinatus** *Hook. f. Fl. Antarct.* i (1844) 87, t. 49.—Larger and softer than the two preceding species, sometimes forming masses 2–3 in. deep and a foot or more in diameter. Leaves conspicuously distichous, and often almost flabellately arranged, densely imbricating, equitant and sheathing at the base; blade $\frac{1}{2}$–$\frac{3}{4}$ in. long, linear-subulate, obtuse, rigid, channelled in front; sheathing base longer and broader, 5–7-nerved. Peduncles terminal, short in the flowering stage, but elongating in fruit, and then often equalling or even exceeding the leaves. Spikelets usually solitary. Flowers and fruit very similar to those of *O. pumilio.*—*Hook. f. Fl. Nov. Zel.* i (1853) 275. O. pumilio *var.* pectinatus *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 797.

North Island: From the summit of Moehau (Cape Colville) to Mount Hikurangi (East Cape), Tongariro, and Ruapehu, and the Ruahine, Kaimanawa, and Tararua Mountains. South Island, Stewart Island: Abundant throughout in mountain districts. Auckland and Campbell Islands: Plentiful in open situations. Altitudinal range from 1500 to 4500 ft., but descends to sea-level in Stewart Island and the Auckland Islands.

The strongly distichous leaves and larger size give this plant a different appearance from any state of *O. pumilio* I have seen. I have therefore restored it to the rank of a species.

13. **UNCINIA** Pers. 1807

Perennial herbs, usually tufted and grass-like, with fibrous roots. Culms erect, terete or obscurely trigonous, striate, leafy at the base. Leaves very narrow-linear, flat or involute, often keeled, margins usually scabrid. Spikelets unisexual, arranged in a simple linear or oblong spike; male terminal; females placed lower down. Glumes imbricated all round the axis, ovate or oblong or lanceolate, obtuse or acute or the lower ones awned, concave, 1–3-nerved. Male flowers with 3 stamens; filaments filiform in all the New Zealand species, flat and dilated in some others. Female flowers with the ovary included in a flask-shaped organ called the utricle or perigynium; style long, protruding; branches 3, filiform. Rhachilla produced beyond the mouth of the utricle into a long bristle hooked at the tip. Nut trigonous or subcompressed, enclosed in the persistent more or less enlarged utricle.

A genus of about 30 species, found in New Zealand, Australia, Tasmania, New Guinea, Kerguelen and Amsterdam Islands, and America from Fuegia northwards to the West Indies, Mexico, and the Sandwich Islands. Of the 14 species found in New Zealand, 4 extend to Australia and Tasmania, of which one stretches as far as New Guinea, and another to Kerguelen; while one each is found in temperate South America and in the Sandwich Islands. The remaining 8 are endemic. The genus only differs from *Carex* in the rhachilla being exserted beyond the utricle in the shape of a hooked bristle. The New Zealand species are highly variable and most difficult of discrimination. *U. purpurata, U. caespitosa, U. riparia, U. rupestris,* and *U. filiformis* present an almost unbroken series of forms, and I doubt if any two observers would arrive at the same conclusions respecting them, even if they worked on the same material.

Key to UNCINIA, adapted from Kukenthal.

1. Spikes dense; glumes persistent, not articulate 2
   Spikes often lax; glumes deciduous, articulate 7
2. Utricle hispid above and on margins . . . . . macrolepis
   Utricle glabrous 3
3. Rhizome shortly stolon. ♂ spike gradually contracted; utricles sub-obovate oblong . . . . . fusco-vaginata
   Rhizome caespitae; ♂ spike long, abruptly contracted 4
4. Spikes not 7⅛ cm., Utricle shortly stipulate 5
   Spikes 10-15 cm., utricle long-stipulate. 6
5. Spikes cylind., 2-4 cm.; gl. ovate-obtuse, purple-chestnut, wide white margins, utricles about 2x glumes . . . . . purpurata
   Spikes linear-cylind., 6-8 cm.; gl. oblong-lanceolate, acute, straw-colrd., narrow white margins, utricles hardly exceeding glumes . . . . . caespitosa
6. Leaves red, spikes linear-cylind. 3 mm. glume rather obtuse, utricles exceed. glumes, obsoletely nerved . . . . . pedicellata
   Leaves green, spikes cylind., 5 mm. glumes acute; utricles = glumes; 2 shin prominent lateral nerves . . . . . uncinata
7. Rhizome caespitose, but little elongate . 8
   Rhizome long, stoloniferous 11
8. Spike narrow-oblong, ½-2 cm., somewhat dense, utricles lanceolate-elliptic, 2 raised latera nerves . . . . . rupestris
   Spike elongate, rather lax-fld, utricles narrow-oblong, many nerved 9
9. Utricle saabrid above . . . . leptostachya
   Utricle glabrous 10
10. Culm slender triquet, Lvs. much exceed. culm . . . . . riparia
    Culms rigid terete, lvs. red, much shorter than culm . . . . . rubra

11. Rhizome hard, spikes dense-fld. utric. elliptic. . . . . compacta
    Rhizome thin, spikes lax 12
12. Utricles lanceol.-elliptic, 5½ mm., suberect . . . . . tenella
    Utricles lanceol.-subulate, 7 mm., finely obliquely patent . . . . . filiformis

Section A. Spike short, rather broad, ⅓–1 in. long, oblong or linear-oblong, more or less dense-flowered.

Culms 2–9 in., rather stout. Leaves shorter than the culms, $\frac{1}{12}$–$\frac{1}{10}$ in. diam. Spike pale, ½–1 in. Utricle scabrid .. 1. *U. macrolepis.*

Culms 2–6 in., weak. Leaves longer than the culms, filiform, $\frac{1}{30}$–$\frac{1}{20}$ in. diam. Spike pale, ⅓–½ in. Utricle lanceolate .. 2. *U. tenella.*

Culms 4–9 in., slender, strict. Leaves shorter than the culms, filiform, $\frac{1}{40}$–$\frac{1}{30}$ in. diam. Spike brownish, ⅓–⅔ in. Utricles conspicuously nerved .. .. 3. *U. nervosa.*

Culms 3–12 in., stout. Leaves flat, grassy, $\frac{1}{12}$–⅛ in. diam. Spike brown or chestnut-brown, ½–1 in. long. Utricles faintly nerved 4. *U. compacta.*

Section B. Spike elongated, 1–6 in. long, linear or narrow linear-oblong, more or less dense-flowered, continuous.

Culms 4–12 in., stout, rigid, furnished at the base with brownish scales. Leaves exceeding the culms, $\frac{1}{12}$–⅛ in. diam. .. 5. *U. fusco-vaginata.*

Culms 6–14 in., stout or slender. Leaves shorter than the stems. Spike brownish, 1–2 in. Glumes oblong-obovate, usually obtuse 6. *U. purpurata.*

Culms 6–14 in., slender. Leaves flat, grassy, $\frac{1}{15}$–⅙ in. broad. Spike pale or green, 1½–3 in. Glumes oblong-lanceolate, acute or acuminate .. .. 7. *U. caespitosa.*

Culms 9–20 in., slender. Leaves flat, grassy, ⅛–¼ in. broad. Spike 3–6 in., linear-elongate. Glumes oblong-lanceolate, brownish .. .. 8. *U. australis.*

Section C. Spike ½–4 in. long, linear, very slender, lax-flowered, usually interrupted towards the base.

Culms 12–24 in., slender. Leaves flat, $\frac{1}{12}$–$\frac{1}{10}$ in. diam. Spike 1½–5 in. Utricles scabrid above .. .. 9. *U. leptostachya.*

Culms 9–20 in., slender. Leaves usually flat, $\frac{1}{30}$–$\frac{1}{10}$ in. diam. Spike 1¼–4 in., green. Glumes shorter than the utricles, in var. *Banksii* barely ½ the length .. .. 10. *U. riparia.*

Red-brown. Culms 6–14 in., rigid. Leaves usually shorter than the culms, $\frac{1}{12}$–$\frac{1}{10}$ in. Spike 1–2 in., rigid. Glumes nearly as long as the utricles .. .. 11. *U. rubra.*

Usually red-brown. Culms 12–24 in., strict and rigid. Spike 1½–3 in. Glumes oblong-lanceolate, not so long as the utricle 12. *U. strictissima.*

Culms 3–12 in., slender. Leaves usually shorter than the culms, flat, $\frac{1}{25}$–$\frac{1}{15}$ in. diam. Glumes brown or chestnut, almost as long as the utricle .. .. 13. *U. rupestris.*

Culms 3–9 in., very slender. Leaves usually longer than the culms, filiform, $\frac{1}{50}$–$\frac{1}{30}$ in. diam. Spike ½–1½ in., extremely slender. Glumes pale, equalling the utricles .. .. 14. *U. filiformis.*

1. **U. macrolepis** *Decne. in Durv. Voy. Pôle Sud. Bot.* ii (1853) 13, t. 6, fig. A.—Rhizome stoloniferous. Culms 2–9 in. high, rather stout, smooth, subrigid, erect or curved, obtusely trigonous, leafy towards the base. Leaves shorter than the culms or equalling them, flat, grassy, $\frac{1}{12}$–$\frac{1}{10}$ in. broad; margins scabrid. Spike rather stout, dense, narrow-oblong, ½–1 in. long; male portion very short, narrow; bract wanting. Glumes ovate, obtuse or the lowest subacute, pale whitish-green with broad scarious margins, many-nerved on the back. Utricles equalling the glumes or rather longer than them, ovate-lanceolate, narrowed at both ends, triquetrous, nerved, scabrid towards the tip, margins ciliate; bristle yellowish, twice the length of the utricle. Nut elliptic-oblong, trigonous.—*Desv. in Gay Hist. Chile*, vi (1853) 230. U. Sinclairii *Boott in Hook. f. Handb. N.Z. Fl.* (1864) 309; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 394; *Kukenth. in Bot. Central.* lxxxii (1900) 99; *Cheesem. Man. N.Z. Fl.* (1906) 799.

Var. **elegans** *Kukenth. in Cheesem. Man. N.Z. Fl.* (1906) 799.—Culms more slender. Leaves numerous, $\frac{1}{20}$–$\frac{1}{15}$ in. broad, exceeding the culms. Spike elongate, $\frac{3}{4}$–$1\frac{1}{4}$ in. long, linear. Glumes cinnamon-brown.

South Island: Nelson—Lake Tennyson, *H. H. Travers.* Canterbury—Broken River, *J. D. Enys!* Otago—Eweburn, Naseby, Hector Mountains, Mount Cardrona, Upper Hawea, *Petrie! Crosby Smith!* Dart Valley, *T. Kirk!* Var. *elegans:* Black's, Otago, *Petrie!* 1200–4000 ft. December–February.

This plant, New Zealand specimens of which were described as a distinct species by Hooker under the name of *U. Sinclairii*, has proved upon investigation by Kukenthal to be identical with the *U. macrolepis* of southern Chile and Fuegia. In New Zealand it ranges from the south of Nelson to Southland, but is nowhere abundant.

2. **U. tenella** *R. Br. Prodr.* (1810) 241.—Rhizome long, slender, emitting creeping stolons. Culms densely tufted, setaceous, smooth and flaccid, 2–6 in. long. Leaves numerous, usually overtopping the culms, flat, grassy, filiform, $\frac{1}{30}$–$\frac{1}{20}$ in. broad. Spike oblong, short, dense, $\frac{1}{3}$–$\frac{2}{3}$ in. long, $\frac{1}{6}$ in. broad; male portion very short, inconspicuous, sometimes reduced to 1 or 2 flowers; female flowers 6–10; lowest glume produced into a setaceous bract usually far exceeding the spike. Glumes lanceolate, acute, pale-fulvous, 1-nerved; margins pale, thin and membranous. Stamens 2 or 3. Utricles slightly longer than the glumes, oblong-lanceolate, obsoletely trigonous, narrowed at both ends, glabrous, faintly nerved; bristle nearly twice the length of the utricle.—*Hook f. Fl. Tasm.* ii (1860) 102, t. 152. *Benth. Fl. Austral.* vii (1878) 433; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 391; *Kukenth. in Pflanzenr.* Heft 38, 66; *Cheesem. Man. N.Z. Fl.* (1906) 799.

Var. **longifructus** *Kukenth. in Pflanzenr. l.c.*—Utricles $\frac{1}{3}$ in. long, yellowish-green, far exceeding the glumes, which are usually 3-nerved on the back.

South Island: Westland—Kelly's Hill, altitude 4500 ft., *Petrie!* Otago—Routeburn, near Lake Wakatipu, in beech forest, *T. Kirk! Petrie!* Clinton Valley, *Petrie!* End Peak, *Crosby Smith!* 2000–5000 ft.

Mr. Petrie's specimens from Kelly's Hill cannot be distinguished from the Australian plant, but var. *longifructus* is at once separated by the large fruit, which is nearly twice the size of that of the type. It appears to be confined to New Zealand.

3. **U. nervosa** *Boott ex Hook. f. Fl. Tasm.* ii, 102, t. 153A.—Culms densely tufted, slender, strict and wiry, 4–9 in. high, leafy at the base only. Leaves shorter than the culms, strict, erect, wiry, filiform, $\frac{1}{40}$–$\frac{1}{30}$ in. diam.; margins involute. Spike much more slender than in *U. compacta*, and not so dense, $\frac{1}{3}$–$\frac{2}{3}$ in. long, about $\frac{1}{6}$ in. diam.; lowest glume sometimes produced into a filiform bract. Glumes ovate-lanceolate, subacute, pale-brown, keel distinctly 3-nerved or -plicate; margins thin and membranous, almost scarious. Utricles equalling or slightly exceeding the glumes, oblong-lanceolate, narrowed at both ends, trigonous, glabrous, distinctly nerved; bristle about twice the length of the utricle. Nut trigonous.—*Cheesem. Man. N.Z. Fl.* (1906) 800. U. compacta *var.* nervosa *C. B. Clarke in Journ. Linn. Soc.* xx (1884) 395. U. Cheesemaniana *Boeck. in Engl. Bot. Jahr.* v (1884) 521.

South Island: Nelson—Mount Arthur Plateau, *T. F. C.* Otago—Maungatua, *Petrie!* 2000–5000 ft.

Dr. Kukenthal considers that the Tasmanian species described by Boott under the name of *U. nervosa*, together with the plant from the Mount Arthur Plateau associated with it by myself, are both referable to Raoul's *U. rupestris*, originally discovered at Akaroa. I regret that I am unable to agree with this opinion, which is not shared by any other worker in the genus. I take it that *U. nervosa* naturally falls into the

neighbourhood of *U. compacta*, whereas the true *U. rupestris* of Raoul, judging from his plate and description, is closely allied to *U. riparia*. This view was also held by Mr. C. B. Clarke, with whom I had some correspondence on the subject.

4. **U. compacta** *R. Br. Prodr.* (1810) 241.—Rhizome creeping, stoloniferous. Culms rather stout, rigid, obscurely trigonous, leafy towards the base, variable in size, in dry open or alpine situations often dwarfed to 2 in. or even less, in moist sheltered or shaded localities attaining 8–10 in. Leaves usually shorter than the stems but sometimes equalling or even exceeding them, subrigid, flat, grassy, striate, $\frac{1}{12}$–$\frac{1}{8}$ in. broad; margins scabrid. Spike short, stout, dense, oblong, $\frac{1}{2}$–1 in. long by about $\frac{1}{4}$ in. diam., pale greenish-brown to chestnut-brown; the lowest glume sometimes produced into a leaf-like bract occasionally exceeding the spike. Glumes ovate-lanceolate, acute or subacute; keel greenish, 1–3-nerved; margins pale-brown, membranous. Stamens 3. Utricles about equalling the glumes, oblong-lanceolate, narrowed at both ends, trigonous, glabrous, smooth or faintly nerved, spreading when fully ripe; bristle stout, about twice the length of the utricle. Nut trigonous.—*Hook. f. Handb. N.Z. Fl.* (1864) 309; *Fl. Tasm.* ii (1860) 102, t. 153B; *Benth. Fl. Austral.* vii (1878) 434; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 394; *Kukenth. in Pflanzenr.* Heft 38 (1909) 65; *Cheesem. Man. N.Z. Fl.* (1906) 800. U. divaricata *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 286. U. Clarkei *Petrie in Trans. N.Z. Inst.* xx (1887) 185.

Var. **Clarkei** *Kukenth. in Pflanzenr.* Heft 38 (1909) 185.—Culms taller, often reaching 12 in. Spike longer and not so dense, 1–2 in. long; bract usually overtopping the spike. Glumes paler. Utricles smaller and narrower, and more evidently stipitate.—U. compacta *var.* Petriei *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 800.

Var. **caespitiformis** *Kukenth. in Cockayne Surv. Stewart Is.* (1909) 42.— Rhizome densely tufted, putting out short stolons. Culms and leaves rigid. Spikes narrow. Utricles spreading when mature.

North Island: In mountain districts from Mount Egmont, Ruapehu, and Hikurangi to Mount Hector, not uncommon. South Island, Stewart Island: Abundant in subalpine districts throughout. 1000–5500 ft. December–March. Var. *Clarkei*: Apparently as widely distributed as the species. Var. *caespitiformis*: Mount Anglem, Stewart Island, *Cockayne*.

Kukenthal keeps up Hooker's var. *divaricata* for the reception of most of the New Zealand forms, but the differences are really very trivial, consisting of little more than the taller culms and stouter spikelets.

The geographical range of the species is peculiar. In addition to New Zealand, it is found in Victoria and Tasmania, in Kerguelen, and in Amsterdam Island.

5. **U. fusco-vaginata** *Kukenth. in Bull. Herb. Boiss.* Series 2, vol. iv (1904) 50.—Rhizome thick, woody, shortly stoloniferous. Culms tufted, 4–12 in. long, rarely more, rigid, angled, scabrid above, furnished at the base with brown leafless scales. Leaves exceeding the culms, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, rigid, flat, striate, scabrous, gradually tapering to an acuminate point. Spike linear-oblong, somewhat subclavate, dense-flowered, $1\frac{1}{4}$–$2\frac{1}{2}$ in. long; male portion short, cylindric; bract often absent, but sometimes present and exceeding the spike. Female glumes oblong-lanceolate, subobtuse, pale-ferruginous, green on the back and 3-nerved. Utricle slightly exceeding the glumes, obovate-oblong, about $\frac{1}{4}$ in. long, narrowed at each end, somewhat spongy at the base, finely striate; bristle twice the length of the utricle.—*Kukenth. in Pflanzenr.* Heft 38 (1909) 60. U. compacta *var.* viridis *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 395. U. purpurata *var.* fusco-vaginata *Cheesem. Man. N.Z. Fl.* (1906) 801.

North Island: Ruahine Mountains, *Colenso!* Mount Holdsworth, *W. Townson! Petrie!* Mount Hector, *Petrie! B. C. Aston!* South Island: Mount Duppa (Marlborough), *J. H. Macmahon!* Nelson—Mount Arthur Plateau, *T. F. C.;* Boundary Peak, *W. Townson!* Clarence Valley, *T. F. C.* Canterbury—Craigieburn Mountains, *Cockayne!* Broken River, *T. F. C.* 2000–4500 ft.

About midway between *U. compacta* and *U. purpurata*, and very close to some forms of the latter; but always to be distinguished by the stouter and more rigid habit, and longer and broader leaves.

6. **U. purpurata** *Petrie in Trans. N.Z. Inst.* xvii (1885) 272.—Culms tufted, slender or rather stout, scabrid above, leafy at the base, 6–14 in. high. Leaves usually shorter than the stems but sometimes equalling them, flat or slightly concave, grassy, striate, $\frac{1}{20}$–$\frac{1}{12}$ in. broad; margins scabrid; sheaths at the base dusky-brown. Spike $\frac{3}{4}$–2 in. long, linear-oblong, usually dense, continuous. Male portion short, cylindric; bract absent, or present and exceeding the spike. Glumes oblong or obovate, obtuse or subacute, dark-brown with pale scarious margins, shorter than the utricle. Utricle lanceolate, tapering at both ends, plano-convex, quite glabrous, faintly nerved, about $\frac{1}{4}$ in. long; bristle nearly twice as long as the utricle.—*Cheesem. Man. N.Z. Fl.* (1906) 801; *Kukenth. in Pflanzenr.* Heft 38 (1909). Trans. 42 : 209 var. subcaespitosa Kük

Var. **robusta** *Petrie in Trans. N.Z. Inst.* xvii (1885) 272.—Culms shorter and stouter, scabrid above. Leaves as long as the culms, $\frac{1}{10}$ in broad.

South Island: Otago—Not uncommon in mountain districts. 500–2000 ft.

This approaches very near to some states of *U. caespitosa*, to which I am inclined to refer Kukenthal's var. *subcaespitosa* (*Pflanzenr.* Heft 38 (1909) 61).

7. **U. caespitosa** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 287.—Culms tufted, slender, leafy, 6–14 in. high. Leaves longer or shorter than the culms, flat, grassy, very variable in width, from $\frac{1}{15}$–$\frac{1}{6}$ in. broad; margins scabrid. Spike $1\frac{1}{2}$–3 in. long, narrow-oblong or almost linear, rather dense or lax but not interrupted; male portion very short; bract variable, broad and foliaceous or narrow and setaceous. Glumes lanceolate or oblong-lanceolate, acute or acuminate, membranous, green or pale-green, usually equalling the utricle. Utricles about $\frac{1}{4}$ in. long, oblong-lanceolate, suddenly narrowed above, smooth or faintly nerved; bristle about twice the length of the utricle.—*Hook. f. Handb. N.Z. Fl.* (1864) 310; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 393; *Cheesem. Man. N.Z. Fl.* (1906) 801; *Ill. N.Z. Fl.* ii (1914) t. 213; *Kukenth. in Pflanzenr.* Heft 38 (1909) 61. U. horizontalis *Col. in Trans. N.Z. Inst.* xv (1883) 334.

Var. **collina** *Petrie in Trans. N.Z. Inst.* lii (1920) 19.—Forming sward-like patches. Culms and leaves shorter than in the type, the latter flat, grassy, thickened at the tips. Spikes dense-flowered, often subclavate.

Var. **minor** *Kukenth. in Cheesem. Man. N.Z. Fl.* (1906) 802.—Smaller and more slender. Leaves narrower. Spike shorter, much more slender.—*Pflanzenr.* Heft 38 (1909) 61.

North and South Islands, Stewart Island: In hilly or mountainous localities from Hokianga southwards, not uncommon. Sea-level to 4000 ft. November–January. Var. *collina:* Mount Hikurangi, *Petrie* and *Adams!* Ruahine Mountains, *B. C. Aston!* Tararua Mountains, *Petrie!*

An exceedingly variable plant, forms of which are not separated by any strict line of demarcation from *U. purpurata, U. riparia, U. rupestris,* and *U. filiformis.* Its chief characters are the rather broad flat leaves, not very lax narrow-oblong spike, pale-green glumes which are usually as long as the utricles or nearly so, and rather large oblong-lanceolate acuminate utricles, averaging $\frac{1}{4}$ in. long.

8. **U. australis** *Pers. Syn.* ii (1807) 534.—Culms densely tufted, tall, slender, smooth, 9–20 in. high, leafy at the base. Leaves long, usually considerably overtopping the culms, flat, striate, $\frac{1}{8}$–$\frac{1}{4}$ in. broad; margins scabrid. Spike linear-elongate, 3–6 in. long, $\frac{1}{6}$–$\frac{1}{4}$ in. broad, dense except sometimes at the base, cylindrical; male portion narrower, variable in length, occupying $\frac{1}{3}$–$\frac{1}{6}$ of the spike; bract long, leafy, usually exceeding the spike. Glumes oblong-lanceolate, acute, 1-nerved, at first pale-green, but brown or chestnut in fruit, upper about equalling the utricle, lower sometimes exceeding it. Stamens 3. Utricle elliptic-oblong, narrowed at both ends, sometimes almost fusiform, triquetrous, faintly nerved; bristle stout, nearly twice the length of the utricle.—*A. Cunn. Precur.* (1836) n. 286; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 287; *Handb. N.Z. Fl.* (1864) 309; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 393; *Cheesem. Man. N.Z. Fl.* (1906) 802. U. compacta *A. Rich. Fl. Nouv. Zel.* (1832) 118 (*not of R. Br.*). U. Lindleyana *Kunth. Enum.* ii (1837) 526. U. scaberrima *Nees in Linnaea*, ix (1834) 305. U. rigidula *Steud. Cyp.* (1855) 245. U. alopecurioides *Col. in Trans. N.Z. Inst.* xv (1883) 335. U. bracteata *Col. l.c.* xvi (1884) 341. U. polyneura *Col. l.c.* xix (1887) 270. Carex uncinata *Linn. f. Suppl.* (1781) 413; *Forst. f. Prodr.* (1786) n. 338. U. uncinata *Kukenth. in Pflanzenr.* Heft 38 (1909) 62.

Var. **clavata** *Kukenthal MS.*—Spike clavate, often $\frac{1}{2}$ in. broad at the top of the female portion; glumes densely crowded. Other characters as in the type.

Var. **ferruginea** *C. B. Clarke MS.* — Agreeing with the type in size and habit, but glumes longer and narrower, sometimes twice the length of the utricle, lanceolate or subulate-lanceolate, chestnut-brown with a green usually 3-nerved keel. Utricles with a longer beak.—U. ferruginea *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 288, t. 64B; *Handb. N.Z. Fl.* (1864) 309; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 394. U. nigra *Col. in Trans. N.Z. Inst.* xvii (1885) 253. U. variegata *Col. l.c.* xx (1888) 211.

Var. **pedicellata** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 54.—Leaves often reddish, but by no means invariably so. Spike longer and narrower than in the type. Glumes somewhat shorter. Utricles more stipitate.—U. pedicellata *Kunkenth. in Pflanzenr.* Heft 38 (1909) 61.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: The species and var. *pedicellata* abundant throughout; var. *ferruginea* not uncommon from Te Aroha southwards. Var. *clavata:* Near Wellington, *T. Kirk!* Otira Gorge, *T. Kirk! T. F. C.;* Mount Cook district, *T. F. C.* Sea-level to 3000 ft. November-February.

Easily recognized by the large size and very long cylindrical dense-flowered spike. I agree with Mr. Petrie in reducing Kukenthal's *U. pedicellata* to the position of a variety, for the differences between the two are very slight, and it is only in Stewart Island that *U. pedicellata* has a predominantly red colouration. Kukenthal's var. *laxior*, recorded by Carse (*Trans. N.Z. Inst.* xlviii (1916) 240) I cannot treat as more than a tall luxuriant form.

C. B. Clarke, Boeckeler, and Kukenthal all consider that *U. australis* extends to the Sandwich Islands. But Hawaiian botanists treat their plant as a different species, giving it the name of *U. Lindleyana* Kunth.

The oldest name of the species is *Carex uncinata* Linn. f. Kukenthal has therefore adopted the name of *Uncinia uncinata* in his monograph of the genus. But Persoon, who founded the genus, obtained his generic name by converting the adjective "uncinata" into the substantive "Uncinia." The meaning of the two words is identical, and the difference in orthography very small. The name "uncinata" Persoon rejected altogether, no doubt from its too close resemblance to Uncinia. It appears to me that such a name is in conflict with Rule 55 of the International Rules of Botanical Nomenclature, which provides that specific names shall be rejected when they merely repeat the generic name. I therefore retain the name of "australis" in this work.

9. **U. leptostachya** *Raoul Choix* (1846) 12, t. 5B. — Rhizome short. Culms densely tufted, slender, trigonous and scabrid above, leafy at the base, 1–2 ft. high; sheaths brown or purplish-red at the base. Leaves usually much longer than the culms, slender, flat, $\frac{1}{12}$–$\frac{1}{10}$ in. broad; margins scabrid. Spike 1½–5 in. long, very slender, lax-flowered; male portion short, almost filiform; bract setaceous or filiform, longer or shorter than the spike, sometimes wanting. Glumes laxly placed, often distant in the lower part of the spike, oblong-lanceolate, acute or obtuse, from ½ as long to as long as the utricle, green or purplish-red, 1-nerved on the back, membranous. Utricle narrow-lanceolate or almost fusiform, trigonous, distinctly scabrid above, faintly nerved; bristle twice as long as the utricle.—*Hook. f. Fl. Nov. Zel.* i (1853) 286; *Handb. N.Z. Fl.* (1864) 309; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 389; *Cheesem. Man. N.Z. Fl.* (1906) 803; *Kukenth. in Pflanzenr.* Heft 38 (1909) 62. U. scabra *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 285. U. disticha *Col. in Trans. N.Z. Inst.* xx (1888) 210.

North and South Islands, Stewart Island.—From Mangonui southwards, not uncommon. Sea-level to 3000 ft. November–January.

The distinctly scabrid utricles at once separate this from all its allies. Its habit is that of coarse states of *U. riparia*. Kukenthal keeps up Boott's *U. distans* as a variety. I must confess my inability to find any distinguishing characters.

10. **U. riparia** *R. Br. Prodr.* (1810) 241. — Rhizome tufted. Culms slender, leafy, triquetrous, slightly scabrid above, 9–20 in. high. Leaves equalling or exceeding the culms, flat or slightly involute, $\frac{1}{20}$–$\frac{1}{10}$ in. broad, somewhat rigid; margins scabrid. Spike linear, 1½–4 in. long, lax and often interrupted below, denser above, $\frac{1}{8}$–$\frac{1}{6}$ in. broad; male portion variable in length; bract usually wanting, but sometimes present and exceeding the spike. Glumes lanceolate or oblong-lanceolate, subacute or obtuse, 1-3-nerved. Utricles exceeding the glumes, suberect, oblong-lanceolate, narrowed towards a spongy and stipitate base, faintly nerved, about ¼ in. long.—*Boott in Hook. f. Fl. Tasm.* ii (1860) 102, t. 152B; *Benth. Fl. Austral.* vii (1878) 432; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 392; *Cheesem. Man. N.Z. Fl.* (1906) 803; *Kukenth. in Pflanzenr.* Heft 38 (1909) 63. (?) U. obtusata *Col. in Trans. N.Z. Inst.* xvi (1884) 341.

Var. **affinis** *Colenso ex C. B. Clarke l.c.* 392.—Culms 12–24 in. high, weak. Spikes longer, 2–4 in., lax-flowered. Utricles longer than the glumes.—*Kukenth. l.c.* 63. U. laxiflora *Petrie in Trans. N.Z. Inst.* xvii (1885) 271. Barely separable as a variety.

Var. **Banksii** *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 392.—Leaves narrower, almost filiform, $\frac{1}{30}$–$\frac{1}{20}$ in. broad. Glumes very short, often not more than half the length of the utricle.—U. Banksii *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 287; *Handb. N.Z. Fl.* (1864) 310. U. capillaris *Col. in Trans. N.Z. Inst.* xx (1888) 210.

Var. **Hookeri** *Kukenth. in Pflanzenr.* Heft 38 (1909) 63.—Culms smaller, 3–8 in. long, weak, smooth. Spike continuous, 1¼–1¾ in. long. Glumes chestnut. Utricles equalling the glumes.—U. Hookeri *Boott in Hook. f. Fl. Antarct.* i (1844) 91, t. 51.

North and South Islands, Stewart Island: The typical state from the Pirongia Mountain and Taranaki southwards; var. *affinis* with much the same distribution, but not so plentiful; var. *Banksii* from the North Cape to Foveaux Strait, but most common in the north; var. *Hookeri* abundant in the Auckland, Campbell, and Antipodes Islands, Macquarie Island.

The best characters of this variable plant are the tall leafy habit, narrow flat leaves, long and linear very lax spike, and pale glumes nearly always shorter than the

utricles. The two varieties *affinis* and *Banksii* differ very slightly from the type; but var. *Hookeri* is more distinct. On the whole, however, I think that Kukenthal is right in regarding it as a variety of *U. riparia*.

In addition to the mainland of New Zealand and the islands to the south of it, *U. riparia* has been recorded from Australia and Tasmania, New Guinea, and Lord Howe Island.

11. **U. rubra** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 287, t. 64, f. A.—Whole plant red, red-purple, or brownish-red, usually forming a continuous sward. Culms 6–14 in. high, stout or slender, strict, rigid, leafy at the base, trigonous and scabrid above. Leaves much shorter than the culms, rarely equalling or exceeding them, flat or slightly involute, rigid or submembranous, striate, $\frac{1}{20}$–$\frac{1}{15}$ in. broad; margins scabrid. Spike 1–2 in. long, rigid, linear, lax, continuous or slightly interrupted towards the base; male portion short; bract wanting. Glumes oblong-lanceolate, acute or obtuse, rigid, red or red-brown, slightly exceeding the utricle, obscurely 1-nerved on the back. Utricle lanceolate, tapering at both ends, glabrous, faintly nerved, about $\frac{1}{5}$ in. long; bristle nearly twice as long as the utricle.—*Hook. f. Handb. N.Z. Fl.* (1864) 310; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 390; *Cheesem. Man. N.Z. Fl.* (1906) 804; *Kukenth. in Pflanzenr.* Heft 38 (1909) 64.

Var. **fallax** *Kukenth. in Pflanzenr.* Heft 38 (1909) 64. — Culms more slender. Leaves usually equalling the culms, $\frac{1}{18}$ in. broad, less rigid.

North Island: Elevated districts of the interior, from the Upper Waipa, Waimarino, and Taupo southwards. South Island, Stewart Island: Not uncommon in mountain districts, descending to sea-level in Stewart Island.

Closely allied to *U. riparia*, but usually well distinguished by the bright-red colour, the rigid terete culms, and the shorter leaves, which seldom equal the culms.

12. **U. strictissima** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 55.—Dark-reddish or greenish-brown, very densely tufted, forming tussocks similar to those of a *Juncus*. Culms 15–25 in. high, strict, firm, erect, deeply grooved, scabrid above. Leaves equalling the culm or rather shorter, flat or deeply concave, $\frac{1}{20}$–$\frac{1}{15}$ in. broad, striate, greenish or reddish-brown, the sheaths more or less rubescent; margins and midrib scabrid. Spike $1\frac{1}{2}$–3 in. long, narrow-linear, slender, rigid, lax-flowered; male portion very short and slender. Bract leafy, from $1\frac{1}{2}$ to twice as long as the spike. Glumes oblong-lanceolate, obtuse or acute, closely appressed, reddish or brownish-green, margins often scarious. Utricle usually longer than the glume, lanceolate, tapering at both ends, faintly nerved. Bristle usually twice as long as the utricle.—U. rigida *Petrie in Trans. N.Z. Inst.* xvii (1885) 271 (*not of Boeck.*). U. rubra *var.* rigida *Cheesem. Man. N.Z. Fl.* (1906) 804. U. rubra *var.* strictissima *Kukenth. in Pflanzenr.* Heft 38 (1909) 64.

South Island, Stewart Island, Auckland Islands: Probably not uncommon from the Clarence Valley southwards, ascending to 3000 ft.

Ann. Sc. Nat. 1948: 2: 117.

13. **U. rupestris** *Raoul Choix* (1846) 13, t. 5A. — Culms densely tufted, smooth, slender, leafy, 4–8 in. high, clothed with sheathing scales at the base. Leaves usually longer than the culms, flat or slightly involute, rigid, channelled, $\frac{1}{25}$–$\frac{1}{15}$ in. broad; margins scabrid. Spike 1–$1\frac{1}{2}$ in. long, narrow linear-oblong, rather dense, male portion short but evident; bract often wanting, but sometimes present and exceeding

the spike. Glumes lanceolate, acute, shining-brown or chestnut, faintly 3-nerved; margins pale. Utricles lanceolate, quite glabrous, faintly nerved, about $\frac{1}{5}$ in. long; bristle about twice as long as the utricle.—*Boott in Hook. f. Fl. Nov. Zel.* i (1853) 286; *Handb. N.Z. Fl.* (1864) 310; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 395; *Cheesem. Man. N.Z. Fl.* (1906) 804; *Kukenth. in Pflanzenr.* Heft 38 (1909) 64.

South Island: Nelson—Mount Arthur Plateau, *T. F. C.* Canterbury—Akaroa, *Raoul.* Ascends to 4000 ft. on the Mount Arthur Plateau.

Whether the *U. rupestris* of Raoul is really conspecific with my plant from Mount Arthur is a question that cannot be settled until some botanist rediscovers Raoul's type. Species of *Uncinia* are by no means easily exterminated, and I entertain little doubt that it still exists at Akaroa, and could be found by a careful search.

14. **U. filiformis** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 286.—Culms densely tufted, extremely slender, filiform, 3–9 in. high, leafy towards the base. Leaves usually much exceeding the culms, very slender, filiform, $\frac{1}{50}$–$\frac{1}{30}$ in. broad; margins involute, scabrid. Spike $\frac{1}{2}$–$1\frac{1}{2}$ in. long, extremely slender, linear, lax, $\frac{1}{15}$–$\frac{1}{10}$ in. broad; bract filiform, exceeding the spike. Glumes oblong-lanceolate, acute or acuminate, membranous, pale, equalling the utricles or nearly so. Utricles $\frac{1}{8}$–$\frac{1}{6}$ in. long, lanceolate, acuminate, smooth and glabrous, faintly nerved; bristle twice as long as the utricle.—*Hook. f. Handb. N.Z. Fl.* (1864) 310; *C. B. Clarke in Journ. Linn. Soc.* xx (1883) 391; *Cheesem. Man. N.Z. Fl.* (1906) 805; *Kukenth. in Pflanzenr.* Heft 38 (1909) 66.

North Island: Pirongia Mountain, *T. F. C.* Hawke's Bay—Ruahine Mountains, *Colenso* n. 1641! (*type of the species*), *H. Hill! Petrie!* Taranaki—Mount Egmont, *Petrie!* Wellington—Tararua Mountains, *H. H. Travers! T. P. Arnold! B. C. Aston! Petrie!* South Island: Not uncommon in mountain woods. Stewart Island: Abundant. 1000–4500 ft.

As I possess one of Colenso's specimens (No. 1641), selected by Dr. Boott as the type of the species, I feel confident as to its determination. Usually it can be recognized without much difficulty by its small size and very slender habit, filiform convolute leaves, small slender spikes, and small narrow utricles, which only slightly exceed the glumes. But large specimens trend towards *U. riparia*, and are sometimes difficult to separate from that plant.

Mr. C. B. Clarke referred the Lord Howe Island *U. debilior* F. Muell. to *U. filiformis*. Judging from descriptions alone, it is a much larger and coarser plant, and I am inclined to think that Kukenthal is more likely to be correct in placing it under *U. riparia*.

14. **CAREX** Linn. 1735.

Perennial herbs. Culms erect, more or less trigonous or rarely terete, often scabrid on the angles. Leaves mostly radical, grass-like, usually scabrid on the margins and keel. Spikelets unisexual or bisexual, rarely dioecious, solitary or more commonly arranged in clusters or spikes, racemes or panicles, all androgynous or the upper male with rarely a few female flowers at the top or base, the lower female often with a few male flowers at the base or top. Glumes imbricate all round the axis. Male flowers of 3 stamens, without perianth or hypogynous bristles. Female flowers consisting of a compressed or trigonous ovary, included in a flask-shaped or urceolate 2-toothed organ called the utricle or perigynium; style-branches 2 or 3, long, filiform, protruding beyond the utricle. Nut lenticular or plano-convex or trigonous, enclosed in the persistent more or less enlarged utricle.

p. 8

An immense genus of probably over 1000 species, of world-wide distribution, but ıst abundant in temperate regions, rare in the tropics, save on high mountains. Of ə 55 species found in New Zealand, no less than 37 are endemic, the remaining 18 ing mostly widely spread.

In revising the New Zealand species for this edition I have found Dr. Kukenthal's .onograph of the genus, issued as Heft 38 of the Pflanzenreich, of very great assistance. t the same time, I have been unable to follow him in all his conclusions. Few New ɔaland botanists will agree with him in reducing *Carex secta*, *C. virgata*, and . *appressa* to one species; or in uniting *C. Cockayniana* and *C. semi-Forsteri* to . *Forsteri*; and there are similar instances of less moment. But these are matters of inor importance, and do not detract from the many excellencies of the work.

Several species of *Carex* have become naturalized in New Zealand. Among these ay be mentioned the European *C. divisa* Huds.; *C. muricata* L.; *C. flacca* Schreb. *!. glauca* Scop.); *C. panicea* L.; and the Australian *C. longifolia* R. Br.

(see Kukenthal's Key)

ection I. Spikelet solitary, simple, terminal.

eaves flat, grassy. Spikelet oblong, many-flowered. Bract short or wanting .. .. 1. *C. pyrenaica.*

eaves terete, strict and wiry. Spikelet ovoid, few-flowered. Bract long .. .. 2. *C. acicularis.*

eaves filiform, flaccid. Spikelet ovoid. Bract wanting .. 3. *C. Wallii.*

c. Enysii, petrie. n.sp.

'ection II. Spikelets several or many, androgynous or rarely dioecious, sessile, arranged in a compact or more or less interrupted spike, less often in a dense or rarely lax panicle. Styles 2.

* Male flowers at the top of the spikelets.

ɜmall, $\frac{1}{2}$–2 in. Spikelets 2–4, compacted into an ovoid head $\frac{1}{4}$–$\frac{1}{3}$ in. long. Utricles elliptic-ovoid, conspicuously winged .. 4. *C. pterocarpa.*

ɜlender, 2–12 in. Leaves almost filiform. Spikelets 3–8, in a dense or lax spike $\frac{1}{2}$–1 in. long. Utricles ovate-lanceolate, beaked, nerved, minutely papillose .. .. .. 5. *C. Kirkii.*

Usually stout, 6–14 in. Leaves flat, grassy. Spikelets 4–10 in a dense spike $\frac{1}{2}$–1 in. long. Utricles ovoid, beaked, strongly nerved, minutely papillose .. .. 6. *C. trachycarpa.*

ɜlender, strict, wiry, 6–18 in. Spikelets 6–10 in a linear spike $\frac{1}{2}$–$1\frac{1}{2}$ in. long. Utricles narrow-lanceolate, nerved, winged above, tapering into a long subulate beak .. .. 7. *C. Muelleri.*

ɜlender 1–3 ft. Spikelets many, in a lax panicle, 4–9 in. long, sometimes reduced to a spike 3–5 in. Utricles narrow-lanceolate, tapering into a long subulate beak .. .. .. 8. *C. kaloides.*

ɜlender, laxly tufted, 1–2 ft. Spikelets many, in a dense or interrupted oblong spike $\frac{3}{4}$–$1\frac{1}{4}$ in. long. Utricles ovoid, swollen at the base, shining, ribbed on the back, contracted into a rather long beak .. .. 9. *C. diandra.*

Stout, harsh, 1–3 ft. Culms acutely triquetrous. Leaves $\frac{1}{5}$–$\frac{1}{2}$ in. broad. Spikelets many, in a stout spike-like panicle 3–7 in. long. Utricles ovoid, conspicuously nerved .. .. 10. *C. appressa.*

Slender, harsh, 1–3 ft. Leaves $\frac{1}{8}$–$\frac{1}{4}$ in. broad. Spikelets many, in a linear spike-like panicle 6–18 in. long. Utricles ovoid, conspicuously nerved .. .. 11. *C. virgata.*

Slender, drooping, 2–4 ft. Spikelets very numerous in a much and laxly branched nodding panicle 1–$2\frac{1}{2}$ ft. long. Utricles broadly ovoid, smooth or indistinctly nerved .. .. 12. *C. secta.*

** Male flowers at the base of the spikelets.

Slender, 4–18 in. Leaves flat, grassy. Spikelets 2–5, pale-green, compacted into a short head or spike. Utricles ovoid, nerved, narrowed into a long beak .. .. 13. *C. inversa.*

Small, depressed, $\frac{1}{2}$–3 in. Leaves involute, wiry. Spikelets 2–3 or solitary. Utricles ovoid at the base; beak very long .. 14. *C. resectans.*

Slender, 3–14 in. Leaves involute, wiry. Spikelets 2–4, brown, compacted into a short head. Utricles broadly ovoid, smooth, nerveless, not beaked .. .. 15. *C. Colensoi.*

Slender, 4–18 in. Leaves flat, grassy. Spikelets 3–5, green, approximate or a little remote. Utricles spreading, narrow-ovoid, spongy at the base, nerved, beaked .. .. 16. *C. stellulata.*

Short, 2–8 in. Leaves flat, grassy. Spikelets 2–4, red-brown, in a dense spike ½ in. long. Utricles elliptic-ovoid, not winged, faintly nerved; beak short .. .. 17. *C. lagopina.*

Stout or slender, 6–18 in. Leaves flat, grassy. Spikelets 4–6, brownish-green, compacted into a lobed spike ¾–1 in. long. Utricles elliptic-ovoid, winged, narrowed into a long beak .. 18. *C. leporina.*

Section III. Spikelets distinct, usually stalked, unisexual; the male spikelets constantly uppermost, rarely mixed with female flowers; the lower spikelets all female or with a few male flowers at the base or apex.

* Styles 2. Nut lenticular or biconvex, not trigonous.

† Female spikelets with the male flowers (when present) at the top of the spikelet, very rarely below. Utricles much compressed, conspicuously nerved; beak very short, with an entire or very minutely 2-toothed mouth.

Culms 3–14 in. Spikelets 3–5, ¼–¾ in. long, sessile or the lowest very shortly stalked. Glumes obtuse. Utricles minutely granular-papillose .. .. 19. *C. Gaudichaudiana.*

Culms 1–2 ft. Spikelets 4–8, 1–3 in. long, the lower ones stalked. Glumes mucronate or even aristate .. .. .. 20. *C. subdola.*

Culms 1–3 ft. Spikelets 6–15. Glumes black-red. Utricles plano-convex, 3–5-nerved on each face .. .. .. 21. *C. Darwinii.*

Culms tall, stout or slender, 1–4 ft. Basal leaf-sheaths transversely fibrillose. Spikelets 8–24, 1–4 in. long, geminate or ternate or quinate, long-stalked and pendulous. Glumes aristate .. .. 22. *C. ternaria.*

Culms slender, 6–18 in. Basal leaf-sheaths not transversely fibrillose. Spikelets 4–6, ½–1½ in. long, solitary or the upper geminate. Glumes scarcely mucronate. Utricle not granular-papillose .. .. 23. *C. Sinclairii.*

†† Female spikelets with the male flowers (when present) at the base of the spikelet, very rarely at the top. Utricle plano-convex or unequally biconvex, beak obviously 2-toothed.

a. Terminal spikelet always mixed with female flowers.

Culms laxly tufted, 9–18 in. Leaves broad, ⅛–¼ in. Spikelets 4–8, stout. Utricles elliptic, sharply serrate above .. 24. *C. Raoulii.*

b. Terminal spikelet very rarely mixed with female flowers.

Culms slender, 1–2 ft. Spikelets 4–7, ½–1 in. long. Glumes orbicular-ovate, obtuse. Utricles densely packed, spreading when ripe, unequally biconvex; margins smooth .. .. 25. *C. dipsacea.*

Culms filiform, 6–18 in., often elongating and prostrate in fruit. Spikelets 3–5, ½–1 in. long, approximate. Utricles plano-convex or nearly so, obscurely nerved; margins serrate above 26. *C. testacea.*

Culms rather stout, 4–8 in., much overtopped by the leaves. Spikelets 3–6, closely approximate, ⅓–1 in. long. Utricles elliptic-ovoid, strongly nerved, unequally biconvex; margins usually smooth .. .. 27. *C. Wakatipu.*

Culms laxly tufted, 6–18 in. Leaves short. Spikelets 2–4, male very stout, clavate. Utricles elliptic-ovoid, unequally biconvex, strongly nerved, purplish-black .. .. 28. *C. devia.*

Culms very slender, 6–18 in., often elongating in fruit. Leaves long, flat, keeled. Spikelets 4–8, ½–2 in. long, narrow; male slender. Utricles narrow-elliptic, turgid, obscurely nerved; margins smooth .. .. 29. *C. lucida.*

Culms reddish, densely tufted, 1–2 ft. Leaves strict, semiterete. Spikelets 4–6, ½–1½ in. long. Glumes pale. Utricles elliptic, plano-convex; margins serrate .. .. 30. *C. Buchanani.*

Culms very short, 1–4 in. Spikelets 4–5, $\frac{1}{5}$–$\frac{1}{3}$ in. long, approximate, almost concealed by the leaves. Utricles narrow elliptic-ovoid, plano-convex, narrowed into a long acutely bidentate beak .. .. 31. *C. cirrhosa.*

* Styles 3. Nut trigonous. (Styles often 2 in *C. Berggreni.*)

† Utricles glabrous (or the margins serrate above), hardly spreading when ripe.

a. Small species. Culms 1–5 in. high, overtopped by the leaves. Spikelets 2–4, closely approximate, often concealed by the leaves.

Reddish. Culms very short, $\frac{1}{2}$–$1\frac{1}{2}$ in. Leaves 1–2 in. × $\frac{1}{15}$–$\frac{1}{12}$ in., linear, flat, obtuse. Utricles elliptic, biconvex or obscurely trigonous; margins smooth; beak short. Styles often 2 .. 32. *C. Berggreni.*

Green. Culms 1–3 in. Leaves $\frac{1}{20}$ in. broad, acute. Utricles narrow-ovoid, trigonous; margins serrate; beak rather long .. 33. *C. Hectori.*

Glaucous-green. Culms 1–3 in. Leaves 2–6 in. × $\frac{1}{25}$–$\frac{1}{15}$ in. Utricles broadly ovoid, plano-convex; margins serrate; beak short .. .. 34. *C. decurtata.*

Culms filiform, $1\frac{1}{2}$–4 in. Leaves 4–8 in., very narrow. Utricles elliptic, turgid, plano-convex, beak short .. .. .. 35. *C. filamentosa.*

Brownish-red or green. Culms 1–5 in. Leaves much longer, 3–10 in. × $\frac{1}{30}$–$\frac{1}{15}$ in.; tips often curled and twisted. Utricles elliptic-oblong, trigonous; margins smooth; beak very short 36. *C. uncifolia.*

b. Slender; culms 6–16 in. high. Leaves narrow, $\frac{1}{30}$–$\frac{1}{12}$ in. broad, plano-convex or nearly so. Male spikelets solitary.

Culms 4–10 in. Leaves usually shorter, narrow. Spikelets 3–5, distant. Utricles narrow-ovoid, trigonous; margins smooth; beak short .. .. 37. *C. Dallii.*

Culms 5–15 in. Leaves with broad sheathing bases, tips curled and twisted. Glumes pale. Utricles narrow-ovoid, unequally biconvex; margins smooth; beak short .. .. .. 38. *C. Petriei.*

Culms 6–18 in., filiform. Leaves shorter or longer than the culms. Utricles elliptic-lanceolate, plano-convex; margins sharply serrate; beak long .. .. 39. *C. comans.*

Culms 9–24 in. Spikelets 3–5, short, broad. Utricles broadly ovoid, turgid, biconvex; margins smooth; beak short .. 40. *C. litorosa.*

c. Tall, stout or slender; culms 1–3 ft. high or more. Leaves flat or keeled, $\frac{1}{8}$–$\frac{1}{2}$ in. broad. Male spikelets usually more than one (except in C. dissita).

Culms stout or slender, 1–$2\frac{1}{2}$ ft. Leaves $\frac{1}{4}$–$\frac{1}{3}$ in. broad. Spikelets 4–8, distant, on short peduncles, the lower rarely compound. Male spikelet solitary .. .. 41. *C. dissita.*

Culms slender, 2–3 ft., often elongating in fruit. Leaves $\frac{1}{10}$–$\frac{1}{6}$ in., keeled. Spikelets 5–10, distant; terminal 2–4 male; female slender, pendulous on long filiform peduncles, lower often compound .. .. 42. *C. Solandri.*

Culms stout. Leaves broad. Spikelets 8; terminal 2–3 male; females erect on short peduncles, not compound .. .. 43. *C. ventosa.*

Culms stout, 2–3 ft. Leaves $\frac{1}{8}$–$\frac{1}{5}$ in. broad. Spikelets 5–7; 2 terminal male; female short and stout, $\frac{1}{3}$ in. diam., the lowest remote. Utricles ovoid .. .. 44. *C. longiculmis.*

Culms $1\frac{1}{2}$–2 ft. Leaves $\frac{1}{4}$ in. broad. Spikelets 6–7, 1–$2\frac{1}{2}$ in. long, 3 uppermost male. Glumes linear-lanceolate. Utricles turgidly biconvex, 2-nerved, beak short .. .. .. 45. *C. Chathamica.*

Culms very tall and robust, 2–4 ft. Leaves $\frac{1}{3}$–$\frac{1}{2}$ in. broad. Spikelets 6–12, 2–5 in. long, very stout; terminal 2–4 male. Utricles stipitate, obovoid-oblong .. .. .. 46. *C. trifida.*

†† Utricles pubescent, hardly spreading when ripe; beak short. Nut with a swollen style-base.

Culms 1–4 in. high, overtopped by the leaves. Spikelets 2–5, small, green, closely approximate .. .. .. 47. *C. breviculmis.*

Carex lanata in Forst. Fl. 1786 92. N. Sel. non Mud.

††† Utricles glabrous, spreading when ripe; beak short.

Rhizome long, creeping. Culms 4–8 in. Leaves much longer, glaucous. Spikelets 3–6. Utricles large, ¼ in. long, ovoid, turgid, corky, smooth .. .. 48. *C. pumila.*

Rhizome tufted. Culms 6–16 in., slender. Leaves shorter. Spikelets 3–4, small. Utricles ⅛ in. long, broadly oblong, turgid, strongly nerved, dark-brown .. .. .. 49. *C. Brownii.*

†††† Utricles glabrous, spreading when ripe (except in *C. vacilans*), strongly costate-nerved, narrowed into a long and slender acutely 2-toothed beak (beak shorter and obscurely toothed in *C. Cockayniana*).

Yellowish-green. Culms 2–8 in. Spikelets 3–8, small, stout, approximate. Utricles suddenly narrowed into a long beak 50. *C. Oederi.*

Culms slender, 1–2 ft. Leaves harsh. Spikelets 4–9, distant, very slender, about ⅛ in. broad. Utricles fusiform, hardly spreading .. .. 51. *C. vacilans.*

Culms rather slender, 1–2 ft. Leaves harsh. Spikelets 5–8, distant, ⅕–¼ in. broad; terminal one often mixed with female flowers. Utricles elliptic-lanceolate; beak short, obscurely 2-toothed .. .. 52. *C. Cockayniana.*

Culms stout or slender, 1–3 ft. Leaves harsh. Spikelets 5–9, distant or the upper approximate; terminal one always largely mixed with female flowers. Utricles elliptic-lanceolate; beak long .. .. 53. *C. semi-Forsteri.*

Culms stout, 1½–3 ft. Leaves harsh. Spikelets 5–9, distant; terminal 1–3 wholly male. Utricles elliptic-oblong; beak long 54. *C. Forsteri.*

Culms stout or slender, 1–3 ft. Leaves soft, grassy. Spikelets 3–5, approximate or the lowermost remote; terminal one male. Utricles ovate-lanceolate, stipitate; beak long, linear, with 2 almost pungent teeth .. .. 55. *C. pseudo-cyperus.*

1. **C. pyrenaica** *Wahl. in Vet. Akad. Nya Handl. Stockh.* xxiv (1803) 139.—Culms slender, densely tufted, leafy at the base, 2–9 in. high, rarely more. Leaves numerous, longer or shorter than the culms, flat, grassy, $\frac{1}{25}$–$\frac{1}{15}$ in. broad, grooved beneath; margins scabrid. Spikelet solitary, terminal, dark chestnut-brown, ⅓–¾ in. long, oblong or elliptic-oblong, densely many-flowered; male flowers at the top; bract wanting or very short. Glumes membranous, deciduous; of the female flowers ovate or ovate-oblong, acute or obtuse, shorter than the utricle; of the males narrower, linear-oblong, subacute. Utricle stipitate, lanceolate or almost fusiform, gradually narrowed into an obliquely bifid beak, unequally biconvex or almost plano-convex, smooth, spreading or reflexed when ripe. Styles usually 2 in New Zealand examples, usually 3 in European or American. Nut oblong, lenticular.—*Hook. f. Fl. Nov. Zel.* i (1853) 280; *Handb. N.Z. Fl.* (1864) 312; *Boott Ill. Car.* iv (1867) 148, t. 475–76; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 424; *Man. N.Z. Fl.* (1906) 810; *Kukenth. in Pflanzenr.* Heft 38 (1909) 104.

Var. **cephalotes** *Kukenth. l.c.* 106.—Spikelet ovate or subglobose, much smaller. Utricle broader than in the typical form.—C. cephalotes *F. Muell. in Trans. Phil. Soc. Vict.* i (1855) 110.

North Island: Mounts Tongariro and Ruapehu, *Cockayne, T. F. C.;* Ruahine Mountains, *Colenso! E. W. Andrews!* South Island: Nelson—Mount Arthur, Mount Peel, Raglan Mountains, *T. F. C.* Canterbury—Mountains above Arthur's Pass, Mount Dobson Range, Mount Cook district, *T. F. C.* Westland—Kelly's Hill, *Petrie!* Otago—Mountains of the Lake district, *Buchanan!* common on the higher mountains of the central and western districts, *Petrie!* McKinnon's Pass, *F. G. Gibbs!* 3500–6500 ft. December–March.

C. pyrenaica is found on high mountains in most parts of the world. Var. *cephalotes* is only known in Australia and New Zealand, and in the latter country has only been collected on Mount Cardrona and the Remarkables, in Central Otago.

2. **C. acicularis** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 280, t. 63c.—Culms slender, strict, wiry, terete, densely tufted, leafy at the base, 1–6 in. high. Leaves shorter than the culms or equalling them, narrow, strict, rigid, straight or curved, almost terete, grooved down the front, obtuse and slightly scabrid at the tip. Spikelet small, solitary, terminal, $\frac{1}{6}$–$\frac{1}{3}$ in. long, broadly ovoid, red-brown, few-flowered; females 2–8; males 2–4 at the top of the spikelet. Glumes lanceolate or ovate-lanceolate, acute or the lower ones awned, keel green or pale-brown. Utricle shortly stipitate, lanceolate, narrowed above into a rather long beak, obtusely triquetrous; beak serrate, obliquely bifid at the tip. Styles 3, seldom 2. Nut pale, trigonous.—*Boott Ill. Car.* iv (1867) 157, t. 508, f. 2; *Hook. f. Handb. N.Z. Fl.* (1864) 312; *Benth. Fl. Austral.* vii (1878) 437; *Cheesem. in Trans. N.Z. Inst.* xv (1884) 424; *Man. N.Z. Fl.* (1906) 810; *Kukenth. in Pflanzenr.* Heft 38 (1909) 100. C. Archeri *Boott in Hook. f. Fl. Tasm.* ii (1860) 98, t. 160; *Ill. Car.* iv (1867) 156, t. 508, f. 3. C. inconspicua *Col. in Trans. N.Z. Inst.* xviii (1896) 612.

North Island: Mount Hikurangi, *Adams* and *Petrie!* Tongariro, *Herb. Colenso!* Ruahine Mountains, *Colenso! Olsen! E. W. Andrews!* Tararua Mountains, *Petrie!* South Island: Not uncommon on the mountains of Nelson, Canterbury, and Westland. Otago—Mountains above Lake Harris, *T. Kirk!* Old Man Range, *Petrie!* 2500–5000 ft. December–March.

Easily distinguished from *C. pyrenaica* by the strict nearly terete leaves, smaller few-flowered spikelet, and erect subulate bract. It is also found in Victoria and Tasmania.

3. **C. Wallii** *Petrie in Trans. N.Z. Inst.* liii (1921) 371.—A slender more or less matted plant. Leaves few, filiform, flaccid, flat or more or less folded, striate, finely scaberulous towards the tips, $2\frac{1}{2}$ in. long or less. Culms much exceeding the leaves, suberect, more or less curved, glabrous, filiform, more or less trigonous, flaccid, 5 in. long or more. Spikelet solitary, terminal, small, ovoid, ebracteate, $\frac{1}{6}$ in. long; the upper flowers male, the lower female. Glumes of the female flowers membranous; broadly ovate, subacuminate, pale-green, the margins more or less scarious. Utricles longer than the glumes, semiterete or broadly biconvex, slightly winged, faintly 5-nerved on the back, ovate at the base, gradually narrowed above into a slender short entire beak; style-branches 3; nut more or less triquetrous.

South Island: Wet ground at Centre Hill, Southland, *A. Wall.*

Apparently a very distinct species, belonging to the section *Primocarex*, of which *C. pyrenaica* and *C. acicularis* are the only representatives previously known from New Zealand. I have only seen a few scraps, and have consequently largely availed myself of Mr. Petrie's description.

4. **C. pterocarpa** *Petrie in Trans. N.Z. Inst.* xxxi (1899) 353.—A dwarf species, forming depressed patches 3–5 in. diam. Rhizome stout, creeping, clothed with dark-brown scales. Culms very short, stout, densely tufted, $\frac{1}{2}$–1 in. long, rarely more. Leaves sheathing the culms to the top and much exceeding them, $\frac{1}{2}$–2 in. long, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, tapering upwards to an acute point, somewhat rigid and coriaceous, flat or involute, deeply grooved; margins scabrid above. Spikelets 2–4, compacted into a broadly ovoid head $\frac{1}{4}$–$\frac{1}{2}$ in. long, androgynous, pale brownish-green, $\frac{1}{6}$–$\frac{1}{5}$ in. long; lowest bract usually with a foliaceous tip. Glumes ovate, acute, membranous, with a pale-green centre and brown margins. Male flowers at the top of the spikelets, female flowers below. Utricle elliptic-ovoid, plano-convex,

conspicuously winged, strongly nerved, narrowed upwards into a bifid beak; margins and beak serrulate. Styles 2. Nut broadly oblong, lenticular.—*Cheesem. Man. N.Z. Fl.* (1906) 811; *Kukenth. in Pflanzenr.* Heft 38 (1909) 140. C. Thomsoni *Petrie in Trans. N.Z. Inst.* xviii (1886) 298 (*not of Boott*).

South Island: Otago—Hector Mountains, Mount Pisa, Old Man Range, *Petrie!* 4500–6500 ft.

A very distinct little plant.

5. **C. Kirkii** *Petrie in Trans. N.Z. Inst.* xviii (1886) 297.—Rhizome stout, woody, creeping. Culms short, densely tufted, slender, smooth, leafy throughout, $\frac{1}{2}$–3 in. high. Leaves sheathing the whole or greater part of the culm and much longer than it, 2–6 in. long, pale-green, involute, filiform, usually strict and wiry. Spikelets 3–5, compacted into a dense oblong spike $\frac{1}{4}$–$\frac{1}{2}$ in. long, sessile, androgynous, pale-green, few-flowered, $\frac{1}{6}$–$\frac{1}{4}$ in. long; bract usually foliaceous. Glumes ovate-lanceolate, acute or acuminate, membranous, with a green midrib and pale margins. Male flowers 2–3 at the top of the spikelets, sometimes absent in the lower ones; female flowers 3–5 at the base. Utricle ovate-lanceolate, plano-convex, narrowed into a rather long bifid beak, strongly nerved, coriaceous, minutely papillose all over; margins and beak very finely crenulate. Styles 2. Nut broadly oblong, lenticular.—*Cheesem. Man. N.Z. Fl.* (1906) 811; *Kukenth.* in *Pflanzenr.* Heft 38 (1909) 140.

Var. **membranacea** *Kukenthal MS.* — Taller. Leaves 6–10 in. long, sheathing nearly the whole of the culm and twice as long as it. Spikelets 5–6, forming a loose spike $\frac{3}{4}$–1 in. long. Utricle more membranous, narrower, with a longer and more tapering beak.

Var. **elatior** *Kukenthal MS.* — Still taller, the culms 6–12 in. long, the upper half not sheathed by the leaves. Leaves 9–18 in. long, broader, sometimes $\frac{1}{15}$ in., flat or involute at the base. Spikelets 4–8 in a lax spike $\frac{3}{4}$–$1\frac{1}{2}$ in. long, the lowest sometimes remote. Utricle as in var. *membranacea*, but more coriaceous.

South Island: The typical form apparently not uncommon in mountain districts from the Clarence Valley to the south of Otago. Var. *membranacea:* Mount Arthur Plateau, *T. F. C.* Var. *elatior:* Mount Arthur Plateau, *T. F. C.*; Mount St. Bathan's (Otago), *Petrie!* 2500–4500 ft. December–March.

An exceedingly variable plant. Depauperated states, with few-flowered spikelets, are easily mistaken for *C. resectans*, although the position of the male flowers at once separates the two plants. Var. *elatior* approaches *C. trachycarpa*, but is smaller and more slender, with narrower leaves, the inflorescence is much more lax, and the utricles are smaller and narrower.

6. **C. trachycarpa** *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 413.—Culms densely tufted, stout or rather slender, trigonous, scabrid above, 6–14 in. high. Leaves longer or shorter than the culms, flat, grassy, striate, $\frac{1}{12}$–$\frac{1}{8}$ in. broad; margins slightly scabrid above. Spikelets 4–10, compacted into an oblong or linear-oblong spike $\frac{1}{2}$–1 in. long, androgynous, brown or pale-brown, ovoid, $\frac{1}{6}$–$\frac{1}{3}$ in. long; lowest bract leafy, shorter or longer than the spike. Glumes ovate, acuminate or awned, pale-chestnut or pale-brown, with pale-green midribs and hyaline margins. Male flowers at the top of the spikelets, usually few. Utricle ovoid, plano-convex, narrowed into a short bifid beak, strongly nerved, minutely papillose all over; margins finely crenulate above. Styles 2. Nut oblong, lenticular. —*Cheesem. Man. N.Z. Fl.* (1906) 812; *Ill. N.Z. Fl.* ii (1914) t. 214; *Kukenth. in Pflanzenr.* Heft 38 (1909) 152. C. muricata *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 411, 427.

SOUTH ISLAND: Nelson—Mount Arthur, Mount Peel, Mount Owen, *T. F. C.*; Mount Mantell, *W. Townson!* 3000–4500 ft. December–March.

In my revision of the New Zealand species I erroneously referred this to *C. muricata*, from which it differs altogether in the much smaller differently shaped utricles, which do not spread when ripe, and are minutely papillose on both surfaces.

7. **C. Muelleri** *Petrie in Trans. N.Z. Inst.* xviii (1886) 298. — Pale whitish-green. Rhizome stout, woody, creeping, clothed with brownish sheathing scales. Culms densely tufted, slender, strict and wiry, terete below, compressed or plano-convex above, grooved, perfectly smooth, 6–24 in. high. Leaves shorter than the culms, narrow, $\frac{1}{25}$ in. broad, strict and wiry, concave in front, convex on the back, grooved; margins smooth or slightly scabrid above. Inflorescence nearly dioecious or altogether so; spikelets 6–10, collected into a linear terminal spike $\frac{1}{2}$–$1\frac{1}{2}$ in. long, sessile, few-flowered, about $\frac{1}{4}$ in. long; those of the male plant with an occasional female flower or altogether unisexual, those of the female sometimes with a staminate flower at the top of the spikelets; bracts short. Glumes lanceolate, acuminate or awned, thin and membranous, pale whitish-green. Utricle narrow-lanceolate, plano-convex, nerved, winged above and tapering into a very long bidentate beak, both surfaces minutely papillose above; margins ciliate-serrate. Styles 2. Nut linear-oblong, smooth, lenticular.—*Cheesem. Man. N.Z. Fl.* (1906) 812; *Kukenth. in Pflanzenr.* Heft 38 (1909) 141. C. viridis *Petrie in Trans. N.Z. Inst.* xiii (1881) 332; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 428 (*not of Schlecht. and Cham.*).

SOUTH ISLAND: Nelson—Awatere Valley, *Cockayne;* Clarence Valley, *T. F. C.*; valley of the Stanley, *T. Kirk!* Canterbury—Mackenzie Plains, Lakes Tekapo and Pukaki, *T. F. C.* Otago—Rough Ridge, Clarke's Diggings, Carrick Range, Nevis Valley, Mount Cardrona, *Petrie!* 2000–4000 ft. December–February.

Easily distinguished by the strict whitish-green culms and leaves, almost dioecious inflorescence, and long and narrow utricles. It and *C. kaloides* are close allies of the North American and north Asiatic *C. siccata* Dewey.

8. **C. kaloides** *Petrie in Trans. N.Z. Inst.* xiii (1881) 332.—Pale-green, forming tussocks very similar to those of *Poa australis*. Culms densely tufted, slender, drooping at the tips, obtusely trigonous, grooved, smooth, leafy towards the base, 1–3 ft. high. Leaves shorter than the culms, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, flat or involute, grassy, deeply grooved; margins scabrid above. Inflorescence in small specimens forming a lax linear spike 3–5 in. long; in larger ones a panicle 4–9 in.; branches few, the lowest sometimes 2 in. long. Spikelets $\frac{1}{4}$–$\frac{1}{3}$ in. long, numerous, usually rather distant, pale, few-flowered, either androgynous with the male flowers at the top, or some (usually the upper) wholly male; and others (usually the lower) wholly female; bracts very long, foliaceous, often exceeding the panicle. Glumes ovate-lanceolate, long-acuminate, membranous, pale, almost hyaline. Utricle narrow-lanceolate, narrowed at the base, plano-convex, nerved, gradually tapering upwards into a long subulate bidentate beak, the margins of which are ciliate-serrate. Styles 2. Nut dark-brown, oblong, lenticular.—*Cheesem. in Trans. N.Z. Inst.* xvi (1884) 429; *Man. N.Z. Fl.* (1906) 813; *Kukenth. in Pflanzenr.* Heft 38 (1909) 141.

SOUTH ISLAND: Not uncommon in mountain districts throughout. 800–3500 ft. December–February.

Closely allied to the preceding species, but amply distinct in the larger size and coarser habit, broader flatter leaves, and usually paniculate inflorescence.

Ant. Bot. Hann. St. (1781).

9. **C. diandra** *Schrank in Acta Acad. Mogunt.* (1782) 49. — Rhizome creeping and rooting. Culms laxly tufted, not forming dense tussocks, 1–2 ft. high, slender, wiry, triquetrous, grooved, scabrid above. Leaves shorter than the culms, $\frac{1}{20}$–$\frac{1}{12}$ in. broad, flat, grassy, deeply grooved; margins scabrid. Spikelets small, ovoid, few-flowered, androgynous; male flowers few at the top, brown or brownish-green, collected into a linear-oblong or linear dense or interrupted compound spike $\frac{3}{4}$–$1\frac{1}{4}$ in. long; bract usually obsolete. Glumes almost equalling the utricles, ovate, acute, membranous, pale-brown; margins broad, pale. Utricle rather small, shortly stipitate, ovoid, gibbous or almost cordate at the base, plano-convex or unequally biconvex, brown, shining, smooth on the flat face, more or less distinctly ribbed on the convex side, narrowed into a rather long almost winged serrate bidentate beak. Styles 2. Nut obovoid, biconvex. — *Kukenth. in Pflanzenr.* Heft 38 (1909) 175. C. teretiuscula *Good. in Trans. Linn. Soc.* ii (1794) 163; *Hook. f. Fl. Nov. Zel.* i (1853) 281; *Handb. N.Z. Fl.* (1864) 313; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 427; *Man. N.Z. Fl.* (1906) 813.

North Island: Swampy or peaty places from Lake Taupo southwards, not common. South Island: Abundant throughout. Sea-level to 3000 ft. December–March.

A common plant in the North Temperate Zone, but south of the Equator only known from New Zealand. It is easily distinguished by the slender wiry habit, usually dense spike-like panicles, small spikelets male at the top, and ovoid turgid long-beaked utricles, smooth on one side, but ribbed on the other. Better known to New Zealand and English botanists under the name of *C. teretiuscula* Good.; but Kukenthal has pointed out that Schrank's appellation of *C. diandra* has twelve years' priority.

10. **C. appressa** *R. Br. Prodr.* (1810) 242.—Very stout, harsh and rigid. Rhizome short, creeping. Culms densely tufted, 1–3 ft. high, stout, with the leaves often $\frac{1}{2}$ in. diam. at the base, rigid, grooved, acutely triquetrous with the angles sharply scabrid, leafy at the base. Leaves numerous, usually exceeding the culms, $\frac{1}{5}$–$\frac{1}{2}$ in. broad, hard, rigid, acutely keeled, grooved; keel and margins scabrid with minute recurved denticles. Spikelets small, very numerous, few-flowered, androgynous, male flowers at the top, collected in a long and narrow spike-like panicle 3–7 in. long, the primary branches erect and appressed to the rhachis; bract obsolete. Glumes broadly ovate, acute, concave, membranous, brownish with a pale line down the centre; margins not silvery. Utricle shortly stipitate, broadly ovate, plano-convex, conspicuously many-nerved on each face, contracted into a short 2-toothed beak; margins broad, incurved, conspicuously ciliate-denticulate. Styles 2. Nut elliptic-ovoid, biconvex.— *Raoul Choix* (1846) 40; *Hook. f. Fl. Antarct.* i (1844) 90; *Fl. Tasm.* ii (1860) 99; *Handb. N.Z. Fl.* (1864) 313; *Boott Ill. Car.* i (1858) 46, t. 119, 120; *Cheesem. Man. N.Z. Fl.* (1906) 814; *Kukenth. in Pflanzenr.* Heft 38 (1909) 178 (*excl. vars.*). C. paniculata *F. Muell. Veg. Chat. Is.* (1864) 57; *Benth. Fl. Austral.* vii (1878) 440 (*not of Linn.*). C. paniculata *var.* appressa *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 427.

South Island: Banks Peninsula, *A. Wall;* near Dunedin, *Petrie! Thomson!* Catlin's River, *Petrie;* Milford Sound, *Hector.* Stewart Island: Common near the sea, *Thomson! Cockayne, H. Guthrie Smith!* Chatham Islands: *H. H. Travers!* Auckland and Campbell Islands, Antipodes Island: Abundant, *Hooker, T. Kirk!* and many others.

Kukenthal unites with this species both *C. virgata* and *C. secta.* There is much to be said in favour of this, for it cannot be denied that intermediate forms exist between the three plants, and also between *C. appressa* and the northern *C. paniculata.* In

my revision of the New Zealand Carices, published in 1884, I therefore followed Baron Mueller and Mr. Bentham in placing all three under *C. paniculata*. But, as explained in the Manual, further consideration has led me to alter this opinion, and to keep the species separate. After all, the differences between the three plants are quite as well marked as those between several species of *Carex* admitted by most authors, and for the sake of consistency it appears best to uphold their distinctness. In addition to New Zealand *C. appressa* has been recorded from Queensland, New South Wales, Victoria, South Australia, West Australia, and Tasmania. Kukenthal has also identified two plants from New Caledonia with it.

11. **C. virgata** *Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 282.—Culms densely tufted, 1–3 ft. high, trigonous with the angles sharply scabrid, grooved, leafy at the base. Leaves numerous, much exceeding the culms, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, harsh and rigid, grooved, sharply keeled below, flat above; margins scabrid with numerous sharp recurved denticles. Spikelets small, very numerous, few-flowered, androgynous with the male flowers at the top, arranged in a long and slender spike-like panicle 6–18 in. long; primary branches of the panicle rigid, erect, closely appressed to the rhachis, the lower usually remote and sometimes conspicuously so. Glumes almost equalling the utricles, broadly ovate, acute or acuminate, concave, membranous, brown with a narrow pale line down the centre; margins not silvery. Utricle stipitate, ovoid or triangular-ovoid, often subcordate at the base, plano-convex, conspicuously many-nerved on both faces, contracted into a short 2-toothed beak; margins incurved, conspicuously ciliate-denticulate. Styles 2. Nut broadly ovoid, biconvex.—*Boott Ill. Car.* i (1858) 46, t. 121, 122; *Hook. f. Handb. N.Z. Fl.* (1864) 313; *Cheesem. Man. N.Z. Fl.* (1906) 814. C. collata *Boott in Hook. Lond. Journ. Bot.* iii (1844) 417 (*name only*). C. paniculata *var.* virgata *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 427. C. appressa *var.* virgata *Kukenth. in Pflanzenr.* Heft 38 (1909) 179.

North and South Islands: Abundant in swamps from the Three Kings Islands to Foveaux Strait. I have seen no specimens from Stewart Island. Auckland Islands: A specimen collected by *Hombron* is referred to *C. virgata* by Kukenthal, but I am not aware of any other record. Sea-level to 3000 ft. November–January.

Very close to *C. appressa*, but the culms are more slender and not so acutely triquetrous, the leaves are narrower, and the panicle much longer and narrower, and not so dense. It also occurs in both Australia and Tasmania.

12. **C. secta** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 281.—A very large species. Rhizomes matted, often forming trunk-like masses 2–4 ft. high much resembling the stem of a tree-fern. Culms 2–4 ft., slender, inclined or drooping above, trigonous with the angles scabrid, grooved, leafy at the base. Leaves numerous, as long or longer than the culms, $\frac{1}{10}$–$\frac{1}{6}$ in. broad, grooved, keeled below, flat above; margins scabrid. Spikelets very numerous, pale-brown, small, few-flowered, androgynous with the male flowers at the top, arranged in a much and laxly branched often decompound nodding panicle 1–$2\frac{1}{2}$ ft. long; the primary divisions usually very long and slender, much branched, the spikelets often remote on the branches. Glumes almost equalling the utricles, broadly ovate, acuminate or cuspidate, thin and membranous, pale-brown with a paler line down the centre and scarious hyaline margins. Utricles rather smaller than those of *C. virgata*, shortly stipitate, broadly ovoid, turgid, plano-convex or unequally biconvex, polished and shining, quite smooth or very indistinctly nerved, contracted into a rather broad 2-toothed beak, the margins of which are ciliate-denticulate. Styles 2. Nut broadly oblong, biconvex.—*Ill.*

Car. i (1858) 47, t. 123, 124; *Cheesem. Man. N.Z. Fl.* (1906) 815. C. virgata *var.* secta *Hook. f. Handb. N.Z. Fl.* (1864) 313. C. paniculata *var.* secta *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 428. C. appressa *var.* secta *Kukenth. in Pflanzenr.* Heft 38 (1909) 179.

Var. **sectoides** *Cheesem.*—Culms stout, very rough. Inflorescence decompound; primary divisions dense, contracted, the lower shortly pedunculated. Spikelets longer. Utricles strongly convex on the back, brownish-black.—C. appressa *var.* sectoides *Kukenth. in Pflanzenr.* Heft 38 (1909) 179.

Var. **tenuicaulis** *Petrie in Trans. N.Z. Inst.* lii (1920) 19.—Culms smaller and much more slender. Leaves narrower. Inflorescence sparingly branched. Utricles barely stipitate. Probably only a reduced mountain state.

North and South Islands, Stewart Island: Abundant in swamps from the North Cape southwards. Var. *sectoides.*—Chatham Islands: *Krull, Cockayne.* Var. *tenuicaulis.*—Mountain swamps in Canterbury and Otago, *Petrie! T. F. C., A. Wall!* Chatham Islands: *W. R. B. Oliver!*

Easily distinguished from *C. virgata* by the much larger and laxly branched often decompound nodding panicles, and by the smaller utricles, which are smooth and shining or very indistinctly nerved. The immense tussocks formed by the matted rootstocks are very conspicuous objects in swampy districts, and have had the local name of "nigger-heads" applied to them.

13. **C. inversa** *R. Br. Prodr.* (1810) 242.—Rhizomes long, creeping, often matted and forming a continuous sward. Culms numerous, weak, slender, usually erect, variable in height, 4–18 in., smooth, striate, obtusely trigonous, leafy towards the base. Leaves shorter than the culms, flat or keeled, grassy, $\frac{1}{25}$–$\frac{1}{16}$ in. broad; margins usually smooth. Spikelets 2–5, crowded into a terminal cluster or spike, rarely a little remote, androgynous, pale-green, ovoid, $\frac{1}{4}$–$\frac{1}{3}$ in. long; bracts to the 2 or 3 lower ones long and leafy, far overtopping the inflorescence. Glumes ovate, acuminate or cuspidate, membranous, with a narrow green keel and pale almost hyaline margins. Male flowers at the base of the spikelets, usually few, sometimes absent. Utricle compressed, ovate, plano-convex, narrowed into a rather long beak, more or less distinctly nerved on both faces; margins serrulate above; beak 2-fid. Styles 2. Nut lenticular.—*Hook. f. Fl. Nov. Zel.* i (1853) 281; *Handb. N.Z. Fl.* (1864) 312; *Boott Ill. Car.* iv (1867) 151, t. 488; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 425; *Man. N.Z. Fl.* (1906) 816; *Kukenth. in Pflanzenr.* Heft 38 (1909) 189. C. smaragdina *Col. in Trans. N.Z. Inst.* xxvii (1895) 398.

Var. **costata** *Kukenth. in Pflanzenr.* Heft 38 (1909) 189.—Clums slender. Leaves flaccid. Utricles intense green, with stout brownish nerves on each side.

Var. **Leichardtii** *Boeck. in Linnaea,* xxxix (1875) 70.—Culms taller. Utricles conspicuously winged, abruptly narrowed into a rather long beak.—*Kukenth. l.c.* 189.

North and South Islands: From Mangonui southwards, not uncommon. Var. *costata:* Lake Wanaka, *Petrie!* Sea-level to 3000 ft. November–May.

Recognized without any difficulty by the slender grassy habit, pale spikelets male at the base, and compressed plano-convex beaked utricles. It is a common Australian plant.

14. **C. resectans** *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 413.—Forming broad depressed patches often many feet in diam. Rhizome stout, woody, creeping, much branched, clothed with the fibrous remains of the old leaf-sheaths. Culms very short, usually from $\frac{1}{2}$ to $1\frac{1}{2}$ in. high, rarely more, frequently almost wanting. Leaves few, sheathing the whole

16. C. maricata L. Sp. Pl. 974, 1753.
see Skotts. Svensk. Fledd. Göt Bot. Trad. XV p. 332.

length of the culm and much longer than it, narrow, sometimes almost filiform, involute; margins scabrid. Spikelets 2–3 or solitary, crowded into a compact head ¼ in. long, pale-green, androgynous; bracts 2–3, very long and leafy. Glumes broadly ovate, acuminate or cuspidate; margins thin, pale; keel stout, 1–3-nerved. Male flowers 1–3 at the base of the spikelet, sometimes absent; female flowers 3–8. Utricle ovate below, plano-convex, strongly nerved, narrowed upwards into a long tapering serrate deeply bifid beak. Styles 2. Nut broadly oblong, plano-convex or obscurely trigonous. — *Man. N.Z. Fl.* (1906) 816; *Kukenth. in Pflanzenr.* Heft 38 (1909) 188. C. inversa *var.* radicata *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 425.

South Island: Canterbury—Clarence Valley, Lake Tekapo, Lake Pukaki, *T. F. C.* Otago — Common in the dry upland plains of the interior, *Petrie!* 500–3000 ft. December–March.

Very close to *C. inversa*, but separated by the much smaller size and more rigid habit, wiry almost filiform leaves, short culms sheathed to the top by the leaves, and long-beaked utricles, which are very sharply toothed above. Depauperated states of *C. Kirkii* resemble it in habit, but can be distinguished by the male flowers being at the top of the spikelets.

15. **C. Colensoi** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 281, t. 63B.— Rhizome stout, woody, creeping, often much branched. Culms 3–14 in. high, very slender, almost filiform, weak, flexuous, trigonous, deeply grooved, leafy towards the base. Leaves usually shorter than the culms, but sometimes equalling or even exceeding them, narrow, $\frac{1}{30}$–$\frac{1}{20}$ in. wide at the base, wiry; margins involute. Spikelets 2–4 or solitary, compacted into a terminal cluster, androgynous, broadly ovoid, turgid, dark-brown, ¼–⅓ in. long; bracts 1 or 2, unequal. Glumes broadly ovate, acute or the lower ones cuspidate, membranous; keel narrow, green; sides chestnut-brown; margins broad, white and hyaline. Male flowers at the base of the spikelets, female flowers above. Utricle broadly ovate, plano-convex, not beaked, brown when ripe, smooth, indistinctly nerved; margins serrate above. Styles 2. Nut elliptic-oblong, smooth.—*Hook. f. Handb. N.Z. Fl.* (1864) 312; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 425; *Man. N.Z. Fl.* (1906) 817; *Kukenth. in Pflanzenr.* Heft 38 (1909) 189. C. picta *Col. in Trans. N.Z. Inst.* xxi (1889) 103. not (St. Vincent).

North and South Islands: Not uncommon in hilly districts from the Upper Thames southwards. Sea-level to 4500 ft. November–March.

Also in south-eastern Australia, according to Mr. C. B. Clarke.

C. maricata L. Sp. Pl. 1753: 974.

16. **C. stellulata** *Good. in Trans. Linn. Soc.* ii (1794) 144. — Culms more or less densely tufted, slender, trigonous, leafy at the base, 4–18 in. high. Leaves usually shorter than the culms, flat, grassy, grooved, $\frac{1}{25}$–$\frac{1}{15}$ in. broad; margins scabrid. Spikelets 3–5, approximate in a terminal spike or a little remote, sessile, androgynous, green or pale-brown, about ¼ in. long when mature; lowest bract short, subulate. Glumes ovate, acute or obtuse, membranous, pale-brown or green with a dark-green centre. Male flowers at the base of the spikelets, usually few; females more numerous. Utricle yellowish-green, much longer than its glume, spreading when ripe, giving the spikelet a squarrose appearance, ovate-lanceolate from a rounded and spongy base, plano-convex, many-nerved, narrowed above into a bidentate beak; margins of the beak acute, minutely scabrid, or nearly smooth in most of the New Zealand

17. C. bipartita
17. C. lacheualii

specimens. Styles 3. Nut lenticular.—*Hook. f. Fl. Nov. Zel.* i (1853) 281; *Handb. N.Z. Fl.* (1864) 312; *Kukenth. in Pflanzenr.* Heft 38 (1909) 225. C. echinata *Boeck. in Linnaea,* xxxix (1875) 124; *Benth. Fl. Austral.* vii (1878) 439; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 426; *Man. N.Z. Fl.* (1906) 817.

Var. **australis** *Kukenth. l.c.* 230.—Culms and leaves flaccid. Utricles with the margins smooth or scarcely scabrid.—C. debilis *T. Kirk in Trans. N.Z. Inst.* x (1878) 412 (*name only*).

North and South Islands, Stewart Island: Marshy places from the Upper Thames Valley southwards, not uncommon. Sea-level to 4000 ft. November–March.

Widely distributed in the temperate portions of the Northern Hemisphere, but only known from Australia and New Zealand in the Southern. In the first edition of this work I followed Bentham and other well-known writers in adopting the name of *C. echinata* Murr. for this species. But the late Mr. C. B. Clarke definitely proved that Murray's plant was identical with the northern *C. muricata,* and Kukenthal has arrived at the same conclusion. Under these circumstances botanists are pretty well agreed in taking up the next-oldest name of *C. stellulata* Good. The plant found in New Zealand is treated by Kukenthal as an endemic variety.

17. **C. lagopina** *Wahl. in Vet. Akad. Nya Handl. Stockh.* (1803) 145.—Culms densely tufted, short, wiry, smooth or scabrid above, leafy at the base, 2–8 in. high. Leaves shorter than the culms, flat, grassy, grooved, $\frac{1}{20}$–$\frac{1}{10}$ in. broad; margins smooth or nearly so. Spikelets 2–4, rarely more, approximate in a short terminal spike about $\frac{1}{2}$ in. long, sessile, androgynous, red-brown, about $\frac{1}{5}$ in. long; lowest bract short, not exceeding its spikelet. Glumes broadly ovate, obtuse or subacute, membranous, red-brown with a green midrib and pale hyaline margins. Male flowers at the base of the spikelets, females above. Utricle rather longer than its glume, red-brown, elliptic-ovate, plano-convex, not winged, faintly nerved, rather abruptly narrowed into a short slender beak. Styles 2. Nut broad, lenticular.—*T. Kirk in Trans. N.Z. Inst.* xxvi (1894) 262; *Petrie in Trans. N.Z. Inst.* xxviii (1896) 593; *Cheesem. Man. N.Z. Fl.* (1906) 818; *Kukenth. in Pflanzenr.* Heft 38 (1909) 213. C. Parkeri *Petrie in Trans. N.Z. Inst.* xiii (1881) 332; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 426.

South Island: Nelson—Dun Mountain Range, *H. H. Travers!* Canterbury—Craigieburn Mountains, *Petrie!* Otago—Hector Mountains, Mount Arnould, near Mount Aspiring, mountains at the head of Lake Wakatipu, *Petrie!* Mount Cardrona, *A. Wall.* 4000–6000 ft. January–March.

Also found in arctic and alpine Europe, north Asia, and North America, but only known from New Zealand in the Southern Hemisphere. Easily distinguished from *C. leporina,* to which it is allied, by the much smaller size and rounder wingless utricles. Certainly indigenous.

18. **C. leporina** *Linn. Sp. Plant.* (1753) 973.—Culms laxly tufted, stout or rather slender, trigonous, scabrid above, 6–18 in. high. Leaves shorter than the culms, flat, grassy, striate, $\frac{1}{10}$–$\frac{1}{8}$ in. broad; margins minutely scabrid. Spikelets 4–6, crowned in an oblong lobed spike $\frac{3}{4}$–1 in. long, sessile, androgynous, ovoid, brownish-green, shining, about $\frac{1}{3}$ in. long; lowest bract like the glumes or rarely with a short leafy point. Glumes oblong-ovate or oblong-lanceolate, acute or subacute, pale-brown with a green midrib and hyaline margins. Male flowers at the base of the spikelets, female above. Utricle equalling its glume, elliptic-ovoid, plano-

convex, winged, striate, narrowed into a long beak; margins and beak finely serrulate. Styles 2. Nut oblong, lenticular, shining.—*Cheesem. in Trans. N.Z. Inst.* xiv (1882) 301; *Man. N.Z. Fl.* (1906) 818; *Kukenth. in Pflanzenr.* Heft 38 (1909) 210.

North Island: Auckland—Near Mauku, *H. Carse!* Waihi, *H. B. Devereux!* Wellington—Ohariu Valley, *T. Kirk!* South Island: Nelson—Picton, *J. H. Macmahon!* not uncommon in the western portion of the district, ascending to 4000 ft. on the Mount Arthur Plateau, *T. F. C.;* near Westport, *W. Townson!* November–January.

A common plant in northern Europe, north Asia, and some parts of North America. It is probably introduced into New Zealand.

19. **C. Gaudichaudiana** *Kunth Enum.* ii (1837) 417.—Rhizome stoloniferous. Culms slender, strict, trigonous, smooth or slightly scabrid above, very variable in height, usually from 4 to 12 in., but sometimes dwarfed to 1 or 2 in., at other times attaining 18 in. Leaves shorter or longer than the culms, narrow, flat, grassy, $\frac{1}{20}$–$\frac{1}{12}$ in. broad. Spikelets 3–5, rarely more or fewer, sessile or the lowest very shortly stalked, erect, close together or a little remote, $\frac{1}{4}$–$\frac{3}{4}$ in. long; terminal one (and sometimes a smaller one near its base) wholly male, linear or linear-oblong; the rest female, often with a few male flowers at the top, oblong, cylindric; bracts long and leafy, the lowest usually exceeding the inflorescence. Glumes oblong or obovate-oblong, obtuse or very shortly mucronate, shorter than the utricle, dark-purple or purplish-black, usually with a narrow pale midrib and margins. Utricle narrow-ovate to orbicular-ovate, much compressed, conspicuously nerved almost to the apex, green spotted with brownish-red when ripe, upper portion minutely granular-papillose; beak very short, almost wanting, entire or minutely 2-toothed. Styles 2. Nut broadly ovate, plano-convex.—*Hook. f. Fl. Tasm.* ii (1860) 99, t. 151A; *Handb. N.Z. Fl.* (1864) 313; *Cheesem. Man. N.Z. Fl.* (1906) 818; *Kukenth. in Pflanzenr.* Heft 38 (1909) 312. C. vulgaris *var.* Gaudichaudiana *Boott Ill. Car.* iv (1867) 169, t. 567; *Benth. Fl. Austral.* vii (1878) 442; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 429. C. caespitosa *R. Br. Prodr.* (1810) 242 (*not of Good.*).

Var. **humilior** *Kukenth. l.c.* 313.—Culms shorter, often curved. Spikelets all approximate, short, oblong-ovate. Utricles broader, ovate.

North and South Islands: Moist places in mountain districts from the Upper Waikato southwards, rarer in the lowlands. Sea-level to 4500 ft. November–February. Var. *humilior:* Not uncommon on the mountains of Nelson, Canterbury, and Otago, *T. F. C., Cockayne! Petrie!*

Also in Australia and Tasmania, and very closely allied to the almost cosmopolitan *C. vulgaris* Fries, differing chiefly in the more compressed and conspicuously nerved utricles.

20. **C. subdola** *Boott in Trans. Linn. Soc.* xx (1846) 142.—Rhizome creeping, stoloniferous. Culms slender, trigonous, slightly scabrid above, 1–2 ft. high. Leaves usually exceeding the culms, pale-green, soft, grassy, $\frac{1}{12}$–$\frac{1}{8}$ in. broad; margins scabrid above. Spikelets 4–8, erect, 1–3 in. long; terminal 1–3 male, usually approximate, sessile, very slender, cylindric; the remainder female, usually with a few male flowers at the top, the upper sometimes geminate, sessile or shortly stalked, the lower solitary, often remote, on longer peduncles; bracts very long and leafy, far exceeding the inflorescence. Glumes

Glumes oblong or obovate-oblong, obtuse or very shortly mucronate, shorter than the utricle, dark-purple or purplish-black, usually with a narrow pale midrib and margins. Utricle narrow-ovate to orbicular-ovate, much compressed, conspicuously nerved almost to the apex, green spotted with brownish-red when ripe, upper portion minutely granular-papillose; beak very short, almost wanting, entire or minutely 2-toothed. Styles 2. Nut broadly ovate, plano-convex.—*Hook. f. Fl. Tasm.* ii (1860) 99, t. 151A; *Handb. N.Z. Fl.* (1864) 313; *Cheesem. Man. N.Z. Fl.* (1906) 818; *Kukenth. in Pflanzenr.* Heft 38 (1909) 312. C. vulgaris *var.* Gaudichaudiana *Boott Ill. Car.* iv (1867) 169, t. 567; *Benth. Fl. Austral.* vii (1878) 442; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 429. C. caespitosa *R. Br. Prodr.* (1810) 242 (*not of Good.*).

Var. **humilior** *Kukenth. l.c.* 313.—Culms shorter, often curved. Spikelets all approximate, short, oblong-ovate. Utricles broader, ovate.

North and South Islands: Moist places in mountain districts from the Upper Waikato southwards, rarer in the lowlands. Sea-level to 4500 ft. November–February. Var. *humilior:* Not uncommon on the mountains of Nelson, Canterbury, and Otago, *T. F. C., Cockayne! Petrie!*

Also in Australia and Tasmania, and very closely allied to the almost cosmopolitan *C. vulgaris* Fries, differing chiefly in the more compressed and conspicuously nerved utricles.

20. **C. subdola** *Boott in Trans. Linn. Soc.* xx (1846) 142.—Rhizome creeping, stoloniferous. Culms slender, trigonous, slightly scabrid above, 1–2 ft. high. Leaves usually exceeding the culms, pale-green, soft, grassy, $\frac{1}{12}$–$\frac{1}{8}$ in. broad; margins scabrid above. Spikelets 4–8, erect, 1–3 in. long; terminal 1–3 male, usually approximate, sessile, very slender, cylindric; the remainder female, usually with a few male flowers at the top, the upper sometimes geminate, sessile or shortly stalked, the lower solitary, often remote, on longer peduncles; bracts very long and leafy, far exceeding the inflorescence. Glumes shorter and narrower than the utricles, oblong, obtuse, emarginate, with an awn of variable length from the centre

of the emargination, dark red-brown or purplish-brown usually with a green stripe down the centre. Utricle ovate, much compressed, conspicuously nerved, green or brownish-green, narrowed into a very short entire or minutely 2-toothed beak. Styles 2. Nut broadly ovate, planoconvex.—*Hook. f. Fl. Nov. Zel.* i (1853) 282; *Handb. N.Z. Fl.* (1864) 314; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 430; *Man. N.Z. Fl.* (1906) 819; *Kukenth. in Pflanzenr.* Heft 38 (1909) 366.

North and South Islands: Abundant in swamps from the North Cape to Nelson, North Canterbury, and Westport. Sea-level to 2000 ft. November–January.

Chiefly distinguishable from *C. Gaudichaudiana* by the larger size, more numerous and much longer often stalked spikelets, and by the awn to the glume, although the last is a variable character. Mr. C. B. Clarke considered it to be a variety of *C. Gaudichaudiana*, an opinion with which I cannot agree.

21. **C. Darwinii** *Boott in Proc. Linn. Soc.* i (1845) 261.—Rhizome thick, creeping, stoloniferous. Culms 1–3 ft. high, stout below, slender and drooping above, sharply triquetrous, faces concave. Leaves numerous, equalling or longer than the culms, $\frac{1}{5}$–$\frac{2}{5}$ in. broad, margins and midrib sharply scabrid; bracts leafy, the lower far exceeding the culms. Spikelets numerous, 6–15, dark ferruginous-brown, distant, long-stalked, pendulous, $\frac{1}{2}$–3 in. long; upper 1–3 male, solitary or the lower geminate; the remainder female but often with a few male flowers at the top, geminate or ternate, lax-flowered at the base. Glumes lanceolate or ovate-lanceolate, dark-brown with a pale keel, 1–3-nerved, cuspidate. Utricle ovate, planoconvex, 3–5-nerved on each face, minutely papillose-granulate and more or less spotted with purple, narrowed into a very short beak with an almost entire mouth. Styles 2. Nut broadly obovoid.—*Hook. f. Fl. Antarct.* ii (1847) 364, t. 145; *Boott Ill. Car.* iv (1867) 156, t. 504–5; *Cheesem. Man. N.Z. Fl.* (1906) 1154; *Kukenth. in Pflanzenr.* Heft 38 (1909) 367.

Var. **urolepis** *Kukenth. l.c.*—Glumes of the female flowers long-awned, much exceeding the utricles.—C. urolepis *Franch. in Miss. Sc. Cape Horn*, v (1889) 376, t. 5.

Chatham Islands: Lowland swamps, *Cockayne! W. R. B. Oliver!* Auckland Islands: *Chapman!* Antipodes Island: *B. C. Aston!*

Also in South America, where it stretches from Chile to the Strait of Magellan and Fuegia. All the specimens hitherto found in New Zealand fall under var. *urolepis*. As a species *C. Darwinii* comes nearer to *C. ternaria* than to any other New Zealand species, principally differing in the utricle and glumes.

22. **C. ternaria** *Forst. f. Prodr.* (1786) n. 549.—Usually very tall and stout. Rhizome thick, stoloniferous. Culms robust, $1\frac{1}{2}$–4 ft. high, triquetrous with the angles very sharply scabrid, faces grooved and striate. Leaves numerous, equalling or exceeding the culms, broad, flat, grassy, grooved, $\frac{1}{5}$–$\frac{1}{2}$ in. broad; margins and midrib beneath sharply scabrid; sheathing scales at the base of the leaves with the margins transversely fibrillose. Spikelets numerous, 8–24, dark-brown, stout, long-stalked, pendulous, 1–4 in. long; upper 1–6 male, solitary or the lower geminate; the remainder female, usually with male flowers at the top, geminate or ternate or even quinate, the lowest on very long peduncles; bracts very long and leafy, overtopping the inflorescence. Glumes lanceolate to oblong-lanceolate or oblong-ovate, obtuse or retuse at the tip, with a stout hispid awn of very variable length but usually exceeding the utricles, dark-brown with a green keel. Utricle ovate, biconvex, turgid, nerved, brownish, narrowed into a very short beak with an entire mouth. Styles 2. Nut

broadly oblong.—*Raoul Choix* (1846) 40; *Hook. f. Fl. Antarct.* i (1844) 89; *Fl. Nov. Zel.* i (1853) 282; *Handb. N.Z. Fl.* (1864) 314; *Boott Ill. Car.* iv (1867) 176, t. 596; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 431; *Man. N.Z. Fl.* (1906) 820; *Kukenth. in Pflanzenr.* Heft 38 (1909) 369. C. geminata *Schkuhr Riedgr.* i (1801) 65; *A. Cunn. Precur.* (1836) n. 290. C. polystachya *A. Rich. Fl. Nouv. Zel.* (1832) 118, t. 21.

Var. **gracilis** *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 431.—Tall, slender. Leaves usually narrower, $\frac{1}{8}$–$\frac{1}{5}$ in. broad. Spikelets numerous, long, often over 4 in., slender, sometimes barely $\frac{1}{6}$ in. diam.

Var. **pallida** *Cheesem. l.c.* — Stout. Leaves strict, rigid, often coriaceous. Spikelets fewer, short, pale, on long filiform peduncles. Utricles broader and more turgid, indistinctly nerved, sometimes with serrate margins.

North and South Islands, Stewart Island, Auckland Islands, Antipodes Island: The typical form and var. *gracilis* abundant throughout, var. *pallida* not uncommon in the mountains of the South Island. Sea-level to 4000 ft. November–February.

Very distinct in its ordinary state, but small slender forms appear to run into *C. subdola* and into the following species. I do not consider that my var. *pallida* can be possibly included in *Boott's* var. *minor*, as has been done by Kukenthal. The late Mr. C. B. Clarke agreed with me in treating var. *minor* as a depauperated state of the type, and he was well acquainted with it.

23. **C. Sinclairii** *Boott MS. in Herb. Kew.*—Rhizome creeping, stoloniferous. Culms slender or rather stout, triquetrous, scabrid above, 6–18 in. high. Leaves shorter or longer than the culms, flat, grassy, striate, $\frac{1}{15}$–$\frac{1}{8}$ in. broad; margins scabrid; sheaths at the base not transversely fibrillose. Spikelets 4–6, erect or nearly so, short, stalked or the uppermost sessile, $\frac{1}{2}$–$1\frac{1}{2}$ in. long; terminal 1 or 2 male, very slender; remainder female, usually with a few male flowers at the top, solitary or the upper geminate, rarely compound at the base, the lower usually on longer peduncles. Glumes oblong or oblong-ovate, tapering upwards, acute or obtuse, not mucronate or the mucro very short and inconspicuous, dark red-brown, unicolorous or with a very narrow pale stripe down the centre. Utricle equalling the glume or barely exceeding it, ovate, much compressed, nerved, narrowed into a short minutely 2-toothed beak. Styles 2. Nut broadly oblong, lenticular.—*Cheesem. Man. N.Z. Fl.* (1906) 820.

South Island: Nelson—Mount Arthur Plateau, Wairau Valley, Hanmer Plains, *T. F. C.* Canterbury—*Sinclair* and *Haast*, n. 138 *in Herb. Kew*; Broken River, Lake Tekapo, *T. F. C.* Westland—Okarito, *A. Hamilton!* Otago—*Hector* and *Buchanan*, *Petrie!* 1000–3000 ft. December–February.

I am indebted to Mr. C. B. Clarke for supplying me with information respecting this, and for identifying some of my specimens. It appears to be a somewhat critical species, differing from depauperated states of *C. ternaria* in the basal leaf-sheaths not being transversely fibrillose, in the much fewer erect spikelets, and barely awned glumes, &c. From *C. Gaudichaudiana*, large states of which approach it in habit, it is removed by the broader harsher leaves, the spikelets often stalked and geminate, the longer glumes not rounded at the tip, and by the utricle not being granular-papillose. I suspect that in the South Island mountain states have been confused with *C. subdola*.

24. **C. Raoulii** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 283.—Yellowish-green or dark-green, laxly tufted, often spreading at the base. Culms rather stout, triquetrous, scabrid on the angles, 9–18 in. high. Leaves longer than the culms, flat, broad, coriaceous, grooved, $\frac{1}{6}$–$\frac{1}{4}$ in. broad, scabrid on the margins and midrib beneath. Spikelets 4–8, all female but usually with a few male flowers below, the uppermost generally with more male

C. haastii Boeck. Flora 1878 166.
C. raoulii Boott Icones haastianae
C. haastii Boeckel Fl. 1882 59. (Boeck.) Kük

flowers below, stout, erect, all approximate and sessile, or less crowded with the lowest one remote and pedunculate, green or greenish-brown, ½–1 in. long, ¼ in. broad; bracts long and leafy. Glumes broadly ovate, thin and membranous, pale-brown, bifid; midrib stout, produced into a short or long hispid awn. Utricle broader and longer than the glumes, elliptic, unequally biconvex, strongly nerved, narrowed into a stout 2-toothed beak; margins serrate above or almost even. Styles 2. Nut broadly oblong, lenticular.—*Hook. f. Handb. N.Z. Fl.* (1864) 314; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 433; *Man. N.Z. Fl.* (1906) 821; *Kukenth. in Pflanzenr.* Heft 38 (1909) 687; *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 215.

South Island: Nelson—Graham River, Wangapeka River, Mount Owen, Jollie's Pass, *T. F. C.*; Fowler's Pass, *T. Kirk!* Lake Tennyson, *R. M. Laing.* Marlborough—Mount Fyffe, *T. Kirk!* Canterbury—Akaroa, *Raoul*; Southern Alps, *Sinclair* and *Haast*; Mount Torlesse, *T. Kirk!* Kowai River, *Cockayne!* Broken River, Upper Waimakariri, Lake Tekapo, Hooker Valley, *T. F. C.* Otago—Lake Wakatipu, Lake Wanaka, Mount Ida, *Buchanan! Petrie!* Bluff Hill, *Cockayne.* 200–4000 ft. December–February.

A distinct species, easily recognized by the broad flat leaves, by the terminal spikelet being always partly female, and by the strongly nerved elliptic utricles, usually serrate above. Mr. Clarke informs me that all Raoul's specimens at Kew have the utricles hairy on the upper half, but I have seen no specimens showing this peculiarity.

25. **C. dipsacea** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 28, t. 7, f. 8–14.—Densely tufted. Culms slender, smooth, erect, leafy, 1–2 ft. high, scarcely elongating in fruit. Leaves numerous, longer than the culms, rather narrow, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, flat, keeled, striate; margins and keel sharply scabrid. Spikelets 4–7, close together except the lowest, which is usually remote, dense-flowered, pale or dark-brown; terminal one male, slender, sometimes mixed with female flowers; remainder female, but often with a few male flowers below, short and broad, ½–1 in. long, sessile or the two lower shortly pedunculate; bracts long and leafy, far overtopping the inflorescence. Glumes rather shorter than the utricles, orbicular-ovate, obtuse, membranous, pale or dark chestnut-brown, midrib vanishing at the apex or shortly excurrent; margins scarious, pale. Utricles densely packed, spreading when ripe, elliptic-ovoid, unequally biconvex or almost plano-convex, smooth, nerveless; margins sharply and distantly serrate above; beak short, 2-toothed. Styles 2. Nut obovoid-oblong, lenticular.—*Cheesem. in Trans. N.Z. Inst.* xvi (1884) 432; *Man. N.Z. Fl.* (1906) 822; *Kukenth. in Pflanzenr.* Heft 38 (1909) 686.

North and South Islands: From the Lower Waikato to Foveaux Strait, not uncommon. Sea-level to 3000 ft. November–January.

Very close to *C. testacea*, but usually recognized without difficulty by the densely packed utricles, spreading on all sides when ripe.

26. **C. testacea** *Sol. ex Boott in Hook. f. Fl. Nov. Zel.* i (1853) 282.—Laxly tufted. Culms very slender, sometimes filiform, smooth or slightly scabrid above, 6–18 in. high, in some varieties elongating in fruit and becoming prostrate, occasionally reaching a length of 4–5 ft. Leaves longer or shorter than the culms, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, flat, usually keeled, striate; margins harsh and scabrid. Spikelets 3–5, approximate, pale-brown; terminal one male, slender; remainder all female, sometimes with a few male flowers below, rarely above, short and broad, ½–1 in. long, ¼–⅓ in. broad, sessile or the lowest shortly peduncled; bracts long and leafy, far overtopping the inflorescence. Glumes broadly ovate, thin and membranous, deeply emarginate or bifid, with a long or short awn from

the centre of the emargination, pale-brown streaked with chestnut, median portion more or less conspicuously 3-nerved. Utricles equalling the glumes or shorter than them, broadly ovate, plano-convex or nearly so, 7–11-nerved on the convex face, polished and shining, purplish at the apex, paler below, or wholly pale-brown; margins more or less distinctly serrate above, rarely even; beak short, with 2 widely divergent teeth. Styles 2. Nut obovoid-oblong, lenticular.—*Hook. f. Handb. N.Z. Fl.* (1864) 314 (*in part*); *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 444; *Man. N.Z. Fl.* (1906) 822; *Kukenth. in Pflanzenr.* Heft 38 (1909) 687.

North and South Islands, Stewart Island: Abundant throughout. Sea-level to 3500 ft. October–January.

The best marks of this variable plant are the comparatively lax habit, very slender culms which often elongate in fruit and become prostrate, usually aggregated spikelets, and plano-convex utricles with nerved faces and serrate margins.

27. **C. Wakatipu** *Petrie in Trans. N.Z. Inst.* xiv (1882) 363.—Laxly tufted, often spreading at the base. Culms short, rather stout, trigonous, smooth, very variable in size, usually 4–8 in. high, but sometimes elongated to 12 or 14 in., and alpine specimens are often dwarfed to 1–2 in. Leaves always much longer than the culms, frequently twice the length, broad, flat, grooved, $\frac{1}{8}$–$\frac{1}{5}$ in. diam.; margins slightly scabrid. Spikelets 3–6, closely packed, pale- or dark-brown; terminal one (rarely two) male, slender; remainder all female, sometimes with a few male flowers below or rarely above, sessile or the lowest shortly pedunculate, $\frac{1}{3}$–1 in. long; bracts very long and leafy, far overtopping the spikelets. Glumes broadly ovate, thin and membranous, bifid, pale-chestnut, sometimes dark-brown; midrib stout, ending in a short awn. Utricle broadly elliptic-ovoid, unequally biconvex, strongly 7–11-nerved, pale-brown to dark-brown; margins usually smooth; beak short, 2-toothed. Styles 2. Nut broadly oblong, lenticular.—*Cheesem. in Trans. N.Z. Inst.* xvi (1884) 434; *Man. N.Z. Fl.* (1906) 823; *Kukenth. in Pflanzenr.* Heft 38 (1909) 687.

South Island: Not uncommon in alpine and subalpine localities throughout. 2500–5500 ft. December-February.

Distinguished from *C. testacea* by the smaller size and more robust habit, broader leaves always much exceeding the culms, closely aggregated spikelets, and more turgid strongly nerved utricles.

28. **C. devia** *Cheesem. in Trans. N.Z. Inst.* xv (1883) 301.—Culms laxly tufted, smooth or nearly so, leafy at the base, 6–18 in. high. Leaves shorter than the culms, spreading, rigid and coriaceous, flat or involute, strongly grooved, $\frac{1}{10}$–$\frac{1}{6}$ in. diam.; margins scabrid. Spikelets 2–4, approximate or the lowest alone remote, dark-brown; terminal one the largest, male, rarely with a few female flowers at the base, rather stout, sometimes almost clavate, $\frac{3}{4}$–$1\frac{1}{2}$ in. long; remainder all female, erect, oblong, $\frac{1}{2}$–1 in. long, sessile or the lowest very shortly pedunculate; lowest bract long and leafy, the rest small. Glumes dark-brown with a pale centre, ovate, acute, emarginate or shortly bifid, the midrib produced into a hispid awn of varying length. Utricle equalling the glumes or rather longer than them, elliptic-ovoid, unequally biconvex or almost plano-convex, strongly nerved on both faces, purplish-black; margins entire; beak short, bifid. Styles 2. Nut broadly obovoid-oblong, compressed.—*Trans. N.Z. Inst.* xvi (1884) 433; *Man. N.Z. Fl.* (1906) 823; *Kukenth. in Pflanzenr.* Heft 38 (1909) 686.

C. coxiana Petrie, C. Mantkini Petrie C. Mcburgii Pet.
C. nekohn P. C. rotoensis P. all Chatham Is.
Trans. 56: 1926: 6-9

SOUTH ISLAND: Nelson—Mount Arthur Plateau, St. Arnaud Mountains, Raglan Range, *T. F. C.*; Dun Mountain, *H. H. Travers!* D'Urville Island, *H. B. Kirk!* 1000–3000 ft. December–January.

Mr. C. B. Clarke considered this to be a variety of *C. lucida*, to which it approaches very closely in the glumes and utricle. But the habit is altogether different, being nearer to some states of *C. testacea*, the leaves are shorter and broader and more coriaceous, the spikelets are fewer in number and shorter and broader, the terminal male one being often clavate, and the utricles are conspicuously nerved on both faces.

29. **C. lucida** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 283.—Densely tufted, usually forming large tussocks. Culms very slender, leafy, smooth or slightly scabrid above, in the flowering stage 12–24 in. high and usually overtopped by the leaves, in fruit often but not invariably elongating and becoming prostrate, sometimes reaching a length of 4 or 5 ft. or even more. Leaves numerous, spreading or drooping at the tips, narrow, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, keeled; margins and keel sharply scabrid. Spikelets 4–8, narrow, erect, cylindric, $\frac{1}{2}$–2 in. long, pale-brown to dark-brown; upper 1–3 male, very slender, unequal in length, close together; remainder female but occasionally with a few male flowers below or rarely at the top, almost sessile or on peduncles of varying length, usually rather distant, the lowermost often remote and occasionally compound at the base; bracts very long and leafy. Glumes broadly ovate, acute or obtuse, rarely very shortly emarginate, cuspidate with a short hispid awn, pale or dark chestnut-brown with a pale keel. Utricle about as long as the glume, elliptic-ovoid, unequally biconvex, smooth or obscurely nerved on the rounded face, shining, from purplish-black to pale-brown; margins smooth; beak short, acutely bidentate. Styles 2. Nut broadly oblong, biconvex. — *Hook. f. Handb. N.Z. Fl.* (1864) 314; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 314; *Man.* 432 *N.Z. Fl.* (1906) 824; *Kukenth. in Pflanzenr.* Heft 38 (1909) 686. C. flagellifera *Col. in Trans. N.Z. Inst.* xvi (1884) 342.

KERMADEC ISLANDS: *W. R. B. Oliver!* NORTH AND SOUTH ISLANDS, STEWART ISLAND: From the North Cape southwards, abundant. Sea-level to 3000 ft. October–January.

A well-known species, easily distinguished by the slender culms, narrow keeled leaves, distant long and narrow spikelets, usually entire glumes, and turgid smooth and polished utricles.

30. **C. Buchanani** *Berggr. in Journ. Bot.* xviii (1880) 104. — Densely tufted, usually reddish-purple, rarely whitish-green. Culms closely packed, slender, strict, erect, 1–2 ft. high, quite smooth. Leaves equalling the culms or longer than them, narrow, strict, semiterete, grooved on the convex face, $\frac{1}{20}$–$\frac{1}{12}$ in. broad; margins scabrid. Spikelets 4–6, linear-oblong, erect, cylindric, $\frac{1}{2}$–$1\frac{1}{2}$ in. long, remote or the upper approximate, pale whitish-green; terminal 1 or rarely 2 male, very slender; remainder female, usually with a few male flowers below, sessile or the lowest shortly pedunculate; bracts long and leafy. Glumes longer than the utricles, broadly ovate with a long hispid awn, pale, membranous; margins lacerate. Utricle elliptic, plano-convex, smooth or faintly nerved on the convex face, spotted with dark-purple; margins ciliate-serrate above; beak rather long, deeply bifid. Styles 2. Nut obovoid-oblong, plano-convex.—*Trans. N.Z. Inst.* xiii (1881) 290; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 431; *Man. N.Z. Fl.* (1906) 825. C. lucida *var.* Buchanani *Kukenth. in Pflanzenr.* Heft 38 (1909) 686. C. tenax *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 27, t. 7, t. 1–7 (*not of Chapm.*).

C. McMahoni Petrie Trans 56: 1926: 6. Petrels Valley

Foxton.

South Island: Abundant in hilly and mountainous districts throughout. Sea-level to 3500 ft. December–January. Sea Wall Red. Count 11. 4. 1936 110.

The chief characters of this species are the strict erect habit, semiterete leaves, pale-coloured glumes, and elliptic plano-convex utricles, the margins of which are serrate above. The reddish-purple colour, which is often constant through large districts, is also seen in *C. comans*, *C. Petriei*, *C. uncifolia*, and others. It probably occurs in the mountainous centre of the North Island, but I have seen no specimens from thence. Kukenthal reduces it to *C. lucida* as var. *Buchanani*, a view with which I am unable to concur. *C. Buchanani* differs markedly in the much more strict and erect habit, in the semiterete and much more coriaceous leaves, in the pale-coloured glumes, and in the plano-convex utricles, which are sharply serrate above, and have a much longer and more deeply bidentate beak. Not only is the aspect of the plant most distinct, so that it can be recognized at a glance, but its characters appear to me to be fairly constant. Dr. Kukenthal remarks that it is connected with *C. lucida* by numerous passage forms; but I have not myself met with specimens that could be so described. I feel sure that all New Zealand botanists familiar with the plant will repudiate any proposal to associate it with *C. lucida*.

31. **C. cirrhosa** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 29, t. 7, f. 27–34.—A dwarf species forming compact glaucous-green or reddish tufts. Culms very short, densely packed, 1–1½ in. high, leafy throughout. Leaves longer than the culms, narrow, flat or almost plano-convex, grooved; tips obtuse, curled and twisted when dry; margins scabrid. Spikelets 4–5, approximate and almost concealed by the leaves, ⅙–⅓ in. long; terminal one male, slender; remainder all female, with or without a few male flowers below, all sessile or the lowest very shortly peduncled; bracts leafy, far exceeding the spikelets. Glumes ovate-lanceolate, entire, cuspidate, whitish-green with a darker midrib. Utricle about equalling the glumes, elliptic-ovoid, plano-convex, nerved, pale, narrowed into a rather long acutely bidentate beak; margins entire or minutely denticulate. Styles 2. Nut lenticular.—*Cheesem. in. Trans N.Z. Inst.* xvi (1884) 435; *Man. N.Z. Fl.* (1906) 825; *Kukenth. in Pflanzenr.* Heft 38 (1909) 683.

Var. **lutescens** *Kukenth. in Cheesem. Man. N.Z. Fl.* (1906) 825. — Culms taller, 2–4 in. high. Spikelets longer and further apart, the lowest one sometimes remote. Utricle narrow-elliptic; beak longer.

South Island: Canterbury—Upper Waimakariri and Lake Lyndon, *Berggren! J. D. Enys! T. Kirk! Cockayne, T. F. C.* December–February.

A very peculiar little plant. 76 (1917) 585

32. **C. Berggreni** *Petrie in Trans. N.Z. Inst.* xviii (1886) 297.—Small, reddish-brown or green, forming broad depressed tufts. Culms branched at the base, very short, stout, spreading, sheathed to the top by the leaves, ½–1½ in. high. Leaves spreading, exceeding the culms, 1–2 in. long, $\frac{1}{20}$–$\frac{1}{12}$ in. broad, linear, quite flat, obtuse, deeply striate, coriaceous; margins smooth or serrate above. Spikelets 2–3, small, ⅙–¼ in. long, usually approximate, all shortly peduncled or almost sessile, red-brown; terminal one male; the remainder female; bracts short, broad. Glumes broadly ovate, obtuse or very shortly cuspidate, membranous, chestnut-brown, usually with a green midrib and paler margins. Utricles rather longer than the glumes, elliptic, biconvex or obscurely trigonous, indistinctly nerved, dark red-brown or almost black above, paler towards the base; margins smooth; beak almost wanting, minutely bifid. Styles 2 or 3. Nut acutely trigonous.—*Cheesem. Man. N.Z. Fl.* (1906) 826; *Kukenth. in Pflanzenr.* Heft 38 (1909) 685, t. 117.

South Island: Canterbury—Upper Waimakariri, *Petrie;* Arthur's Pass, *W. Martin;* margins of lagoons near the Cass River, Lake Tekapo, *T. F. C.* Otago—Mount Pisa, Old Man Range, Mount Kyeburn, *Petrie!* 2500–5000 ft. December–February. Broken R. Basin 7 x 2

One of the most distinct species of the genus. The linear flat leaves, of uniform width throughout, and very obtuse at the tip, are unmistakable. The styles are sometimes 2, sometimes 3, but the acutely trigonous nut shows that the alliance of the species is with the 3-styled division of the genus. My Cass River specimens have narrower leaves and more closely compacted spikelets, and are placed by Kukenthal as var. *angustifolia*.

33. **C. Hectori** *Petrie in Trans. N.Z. Inst.* xxvii (1895) 405.—Culms densely tufted, branched at the base, erect, leafy throughout; 1–3 in. high. Leaves exceeding the culms, green, erect, rigid, flat, striate, about $\frac{1}{20}$ in. broad; tips subacute; margins scabrid above. Spikelets 3–4, closely approximate, small, $\frac{1}{6}$–$\frac{1}{4}$ in. long, red-brown; terminal one male, erect; remainder all female, spreading, ovoid-oblong, sessile or the lowest very shortly pedunculate; bracts long, leafy, overtopping the spikelets. Glumes ovate, acuminate or cuspidate with the stout excurrent midrib, membranous, chestnut-brown with a paler midrib and margins. Utricles narrow-ovoid, trigonous, strongly nerved, narrowed at the base and upwards into an acutely 2-toothed beak; margins ciliate-serrate above. Styles 3. Nut trigonous.—*Cheesem. Man. N.Z. Fl.* (1906) 826; *Kukenth. in Pflanzenr.* Heft 38 (1909) 685.

South Island: Otago—Old Man Range, altitude 5000 ft., *Petrie!*

In the leaves and arrangement of the spikelets this approaches *C. decurtata*, but the narrow-ovoid trigonous utricle with its long serrate beak is quite different from the broad plano-convex utricle of *C. decurtata*. From *C. uncifolia* it also differs in the slender serrate beak of the utricle. From *C. Berggreni* it is removed by the green tapering acute leaves, and larger long-beaked utricles.

34. **C. decurtata** *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 414.—Small, densely tufted, glaucous-green. Culms short, 1–3 in. high, usually sheathed to the top by the leaves. Leaves numerous, much exceeding the culms, 2–6 in. long, $\frac{1}{25}$–$\frac{1}{15}$ in. broad, flat, or concave in front and convex behind, rigid, coriaceous, grooved; tips incurved when dry; margins scabrid. Spikelets 3–5, usually concealed amongst the leaves, short, stout, about $\frac{1}{4}$ in. long, very closely approximate; terminal one male, erect; remainder all female, spreading, ovoid or ovoid-oblong, sessile or the lowest very shortly pedunculate. Glumes broadly ovate or almost orbicular, acute or cuspidate, thin and membranous, reddish-brown or chestnut with a paler centre and margins. Utricles rather longer than the glumes, broadly ovoid or elliptic-ovoid, plano-convex or unequally biconvex, turgid on the back, obscurely nerved; margins thick, serrate above; beak short, stout, sharply bidentate. Styles 3. Nut sharply trigonous.—*Man. N.Z. Fl.* (1906) 827; *Ill. N.Z. Fl.* ii (1914) t. 216; *Kukenth. in Pflanzenr.* Heft 38 (1909) 685. C. cryptocarpa *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 412, 435 (*not of C. A. Mey.*).

South Island: Canterbury—Margins of ponds near Lake Tekapo, altitude 2500 ft. December–February.

A very curious and distinct little species.

35. **C. filamentosa** *Petrie in Trans. N.Z. Inst.* xlviii (1916) 191.—Densely tufted, copiously stoloniferous. Culms filiform, smooth, terete, faintly striate, 1½–4 in. long. Leaves 4–8 in. long, extremely narrow, glabrous, concave above, rounded below, finely serrate at the tip. Spikelets 3–4, crowded, or the lowermost somewhat distant, ovoid, about $\frac{1}{4}$ in. long; uppermost male, very slender; the two lower female, usually with 2–3

male flowers at the top, shortly pedicellate; bracts long, filiform. Glumes ovate, pale, membranous, strongly keeled, gradually narrowed into a short scabrid mucro. Utricles about as long as the glumes, turgid, elliptic, slightly stipitate, plano-convex, with two prominent lateral nerves, and faint intermediate ones, narrowed into a short broad obscurely bidentate beak. Styles 3.

STEWART ISLAND: Table Hill, *W. J. Murdoch!* high lands at Port Pegasus, *T. Kirk!* high lands at the head of Paterson Inlet, *H. Guthrie Smith!*

Probably *C. uncifolia* is the nearest ally of this curious little plant, which is mainly known from cultivated plants. Trans 48 : 191

36. **C. uncifolia** *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 412.—Brownish-red or green, forming lax or dense spreading tufts. Culms short, 1–4 in. high, usually sheathed to the top by the leaves. Leaves numerous, spreading, far exceeding the culms, 3–10 in. long, $\frac{1}{30}$–$\frac{1}{15}$ in. broad, rarely narrower and filiform, concave in front, convex on the back, grooved, tips often curled and twisted when dry; margins finely scabrid above. Spikelets 3–5, short, closely approximate or sometimes the lowest one remote, chestnut-brown to dark-brown, $\frac{1}{6}$–$\frac{1}{4}$ in. long; terminal one male, slender, erect; remainder all female, spreading, ovoid or oblong, all sessile or the lowest very shortly pedunculate. Glumes ovate, obtuse or cuspidate, membranous, chestnut-brown with a green centre; margins sometimes erose. Utricles longer than the glumes, narrowed at the base, elliptic-oblong, trigonous, more or less distinctly nerved, reddish-brown to blackish-brown, rarely pale; margins rounded, entire; beak very short, with an almost entire or obscurely 2-toothed mouth. Styles 3. Nut obovoid, trigonous.—*Trans. N.Z. Inst.* xxiv (1892) 415; *Man. N.Z. Fl.* (1906) 827; *Kukenth. in Pflanzenr.* Heft 38 (1909) 685.

Var. **libera** *Kukenth. in Pflanzenr.* Heft 38 (1909) 685.—Culms longer, not sheathed by the leaves to the top. Spikelets 4–5, often $\frac{1}{2}$ in. long. Glumes of the females notched at the top.

NORTH AND SOUTH ISLANDS, STEWART ISLAND: Apparently not uncommon in mountain districts throughout. 2000–4000 ft. December–February. Var. *libera:* Mount Arthur Plateau, Nelson, *T. F. C.*

37. **C. Dallii** *T. Kirk in Trans. N.Z. Inst.* xxvi (1894) 261.—Small, slender, laxly tufted, usually reddish-brown. Culms very slender, smooth, grooved, 4–10 in. high. Leaves shorter than the culms or almost equalling them, sheathing at the base, narrow, $\frac{1}{30}$–$\frac{1}{15}$ in. broad, concave in front, convex behind, grooved, narrowed into long filiform points; margins slightly scabrid above. Spikelets 3–5, narrow, $\frac{1}{4}$–$\frac{2}{3}$ in. long, more or less distant, the lowermost often almost basal, dark red-brown; terminal one male, slender; remainder all female, sometimes with a few male flowers below, sessile except the lowest, which is on a long filiform peduncle; bracts long, leafy. Glumes ovate, acuminate or slightly awned, membranous, reddish-brown. Utricles narrow-ovoid, obscurely trigonous, smooth or faintly nerved, dark purplish-black; margins entire; beak sharply 2-toothed. Styles 3. Nut trigonous.—*Cheesem. Man. N.Z. Fl.* (1906) 898. C. Traversii *T. Kirk in Trans. N.Z. Inst.* xxvi (1894) 262. C. Gibbsii *Petrie in Trans. N.Z. Inst.* xlvi (1913) 35.

SOUTH ISLAND: Nelson—Source of the Heaphy River, *Dall!* Dun Mountain, *H. H. Travers!* (*C. Traversii*); Cedar Creek, near Denniston, *Petrie!* (*C. Gibbsii*).

Under *C. Dallii* (which is itself very imperfectly known) I have for the present placed Kirk's *C. Traversii* and Petrie's *C. Gibbsii*. I have scanty material of all three. In the first edition of this work I stated my inability to satisfactorily distinguish *C. Dallii* and *C. Traversii*. Dr. Kukenthal is in very much the same position, and has even suggested merging both with *C. Petriei*, which appears to be an extreme view. Mr. Petrie states that his *C. Gibbsii* differs from *C. Dallii* in the short crowded spikelets and long filiform culms. But I have specimens of *C. Traversii* so close to it as almost to destroy the difference. I am therefore leaving the three species for more leisurely study when a satisfactory series of specimens has been obtained.

38. **C. Petriei** *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 413.—Densely tufted, usually brownish-red. Culms stout or rather slender, quite smooth, deeply grooved, leafy, 5–15 in. high. Leaves numerous, longer or shorter than the culms, broad and sheathing at the base, blade narrow, $\frac{1}{30}$–$\frac{1}{10}$ in. broad, deeply grooved, concave in front, convex behind, narrowed into long slender points that are usually curled and twisted when dry; margins scabrid. Spikelets 3–5, narrow-oblong, $\frac{1}{3}$–$\frac{2}{3}$ in. long, more or less approximate but not closely so, the lower one often remote; terminal one male, slender; remainder all female, sometimes with a few male flowers at the base, all stalked, but the stalks of the upper ones sometimes very short; bracts long, leafy. Glumes ovate, acute or shortly cuspidate, thin and membranous, pale, often almost white, but usually more or less stained with chestnut, rarely chestnut-brown; margins often lacerate. Utricles longer than the glumes, narrow-ovoid or elliptic-oblong, biconvex, rather turgid, smooth or obscurely nerved, shining, dark purplish-brown or almost black; margins entire; beak short, 2-toothed. Styles 3. Nut elliptic, trigonous. —*Man. N.Z. Fl.* (1906) 828; *Kukenth. in Pflanzenr.* Heft 38 (1909) 689.

Var. **rubicunda** *Kukenth. l.c.* 690.—Much smaller. Female spikelets shorter. Utricles more conspicuously nerved; beak very short.—C. rubicunda *Petrie in Trans. N.Z. Inst.* xxxi (1899) 355; *Cheesem. Man. N.Z. Fl.* (1906) 825.

South Island: Not uncommon in mountain districts, from Nelson to the south of Otago. 2000–5000 ft. December–February. Var. *rubicunda.*—North Island: Opepe, near Taupo, *T. F. C.* South Island: Lake Te Anau, *Petrie!* Mount Earnslaw, *Cockayne!*

Characterized by the broad sheathing base of the leaves, and their fine curled and twisted points; by the rather small and narrow spikelets, all of which are stalked, and the lower on filiform peduncles; by the usually pale-coloured glumes; and by the narrow-ovoid or elliptic turgid utricles, which are dark purplish-brown or almost black. *C. rubicunda*, I think, is nothing more than a depauperated state of *C. Petriei*, and I have therefore placed it as such, which is the view taken by Kukenthal.

39. **C. comans** *Berggr. in Minnesk. Fisiog. Sallsk. Lund.* (1877) 28, t. 7, f. 15–19.—Densely tufted, pale-green or reddish. Culms very slender, filiform, quite smooth, leafy, usually 6–18 in. high, but sometimes elongating in fruit and prostrate. Leaves longer or shorter than the culms, very narrow, filiform, $\frac{1}{30}$–$\frac{1}{15}$ in. broad, flat or concave in front, slightly rounded at the back, grooved and striate; margins scabrid. Spikelets 5–7, linear-oblong, $\frac{1}{3}$–$\frac{3}{4}$ in. long, $\frac{1}{8}$–$\frac{1}{5}$ in. broad; terminal one (rarely two) male, very slender; remainder all female, sometimes with a few male flowers at the base, usually distant, the lowermost sometimes almost basal, the upper two sessile, the rest on filiform peduncles, that of the lowermost often elongate; bracts long, filiform, far overtopping the spikelets. Glumes ovate, usually bifid, with a short hispid awn, membranous, pale-brown or red-brown; margins lacerate. Utricles rather longer than the glumes, lanceolate or elliptic-lanceolate, plano-convex or unequally biconvex, smooth

C. carei Petrie TNZI. 54:570.

or obscurely ribbed on the convex face, gradually narrowed into a rather long bidentate beak; margins sharply serrate above. Styles 3. Nut trigonous.—*Cheesem. in Trans. N.Z. Inst.* xvi (1884) 446; *Man. N.Z. Fl.* (1906) 829; *Kukenth. in Pflanzenr.* Heft 38 (1909) 689. C. Cheesemanii *Petrie in Trans. N.Z. Inst.* xv (1883) 358; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 437. C. pleiostachys *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 829.

Var. **pulchella** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 829; *Kukenth. l.c.* 689.—Smaller. Spikelets usually 4, the lowermost remote and basal. Utricles shorter and broader, ovate-oblong, often smooth; beak shorter.—C. pulchella *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 29, t. 7, f. 20–26.

C. albula Atlant TNZI. 76:559.

Var. **stricta** *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 415.—Pale whitish-green. Culms short, 4–8 in. high, barely half the length of the strict erect leaves. Spikelets and glumes shining whitish-green. Utricles larger and broader, elliptic-ovoid, pale. Perhaps a distinct species.—*Cheesem. Man. N.Z. Fl.* (1906) 829.

var. subsessilis Kirk in Cheesem Trans 48: 24.

North and South Islands, Stewart Island: Not uncommon from Ahipara and Mangonui southwards. Var. *pulchella:* Bealey, *Berggren!* Maniototo Plain, *Petrie!* Var. *stricta:* Lake Tekapo, *T. F. C.* Sea-level to 3500 ft. November–February.

A very variable species, best separated from its allies by the filiform culms and leaves, narrow rather remote spikelets, and lanceolate or elliptic-lanceolate utricles, sharply toothed above. I have followed Mr. C. B. Clarke in reducing Berggren's *C. pulchella* to *C. comans*, the differences between the two being of no very great importance. In his review of *Carex* in the Pflanzenreich Dr. Kukenthal proposes to re-establish *C. Cheesemanii* as a variety of *C. comans;* but the only difference I can find of any moment is that it has rather broader spikelets and longer culms—characters of no great value. Mr. C. B. Clarke's *C. pleiostachys* (accidentally misprinted *C. plesiostachys* in the Manual, p. 829) I am now convinced is only a trivial form of *C. comans.*

Trans 42: 212

40. **C. litorosa** *Bailey in Memoirs Torrey Club* (1889) 72.—Pale-green, forming compact tufts. Culms densely packed, slender, erect, terete, grooved, quite smooth, leafy, 9–24 in. high. Leaves as long or longer than the culms, sheathing at the base, narrow, $\frac{1}{30}$–$\frac{1}{12}$ in. broad, deeply grooved, flat or concave in front, convex behind, narrowed into long filiform points; margins slightly serrate above. Spikelets 3–5, the lowermost often remote, the others closely placed or a little distant, oblong-ovate, $\frac{1}{4}$–$\frac{3}{4}$ in. long; terminal one male, slender; remainder all female, usually with male flowers either above or below, sessile or the lowermost shortly pedunculate; bracts very long and leafy. Glumes ovate, acuminate with a short or long awn, membranous, pale-brown; margins often lacerate. Utricles as long or rather longer than the glumes, broadly ovoid, turgid, biconvex, smooth or obscurely nerved, reddish-brown; margins smooth; beak short and stout, with 2 divergent teeth. Styles 3. Nut obovoid, trigonous.—*Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 415; *Man. N.Z. Fl.* (1906) 830; *Ill. N.Z. Fl.* ii (1914) t. 217; *Kukenth. in Pflanzenr.* Heft 38 (1909) 690. C. littoralis *Petrie in Trans. N.Z. Inst.* xv (1883) 358; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 437 (*not of Schwein.*). C. australis *T. Kirk in Trans. N.Z. Inst.* xxvi (1894) 262 (*not of Boeck.*).

North and South Islands, Stewart Island: Not uncommon in brackish-water marshes from the Kaipara Harbour southwards. October–January.

Distinguished from *C. comans* by the larger size and stouter habit, broader spikelets, and especially by the broader and more turgid biconvex utricles, with entire margins and smooth or very obscurely nerved faces. The Otago and Stewart Island specimens have rather larger spikelets, with male flowers at the base of the female spikelets, whereas they are usually at the top in northern specimens.

41. **C. dissita** *Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 284.—Densely tufted. Culms slender, smooth, leafy, 1–2½ ft. high. Leaves longer or shorter than the culms, dark-green, flat, broad, grassy, deeply grooved, ⅛–¼ in. diam.; margins scabrid above. Spikelets 4–8, distant, ⅓–1 in. long, ¼–⅓ in. broad, dark-brown; terminal one male, slender, rarely with 1 or 2 much smaller ones near its base; remainder all female, but often with male flowers below, rarely at the top, shortly peduncled and erect, or the lower on longer peduncles and nodding; bracts long, leafy. Glumes broadly ovate, deeply bifid or almost entire, membranous, dark chestnut-brown with paler margins; midrib stout, produced into a short or rather long stout hispid awn. Utricles about equalling the glumes, ovoid, turgid, biconvex, obscurely nerved, pale- or dark-brown, sometimes almost black; margins often serrate above; beak short, with 2 stout often widely divergent teeth. Styles 3. Nut ovoid, trigonous.—*Boott Ill. Car.* i (1858) 65, t. 176; *Hook. f. Handb. N.Z. Fl.* (1864) 316; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 437; *Man. N.Z. Fl.* (1906) 830; *Kukenth. in Pflanzenr.* Heft 38 (1909) 691. C. longeacuminata *Col. in Trans. N.Z. Inst.* xxi (1889) 104. C. polyneura *Col. l.c.*

Var. **Lambertiana** *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 437.—Stouter. Leaves broader, ⅕–⅓ in. Spikelets longer and stouter, 1–2½ in. long. Glumes more deeply bifid.—C. Lambertiana *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 284; *Ill. Car.* i (1858) t. 177; *Hook. f. Handb. N.Z. Fl.* (1864) 317.

Var. **ochrosaccus** *Cheesem.*—Culms usually overtopped by the leaves. Spikelets 4–9, pale, erect, short-stalked, lower often compound. Glumes with longer awns exceeding the utricles. Utricles pale, rather narrower.—C. ochrosaccus *C. B. Clarke MS. in Herb. Kew.*

Var. **monticola** *Kukenthal in Cheesem. Man. N.Z. Fl.* (1906) 831.—Smaller, 6–18 in. high. Leaves narrower. Spikelets 3–5, small, ¼–½ in. long, sessile or very shortly peduncled.

North and South Islands, Stewart Island: The typical form and var. *Lambertiana* abundant throughout. Var. *ochrosaccus:* Whangarei, *H. Carse!* Kaipara, *T. Kirk!* vicinity of Auckland, *T. F. C.* Var. *monticola:* Not uncommon in turfy swamps in the mountains of both Islands. Sea-level to 3500 ft. October–January.

A most abundant and variable species. It can be distinguished from its allies by the broad flat grassy leaves, usually solitary male spikelets, distant stout dark-coloured female spikelets, which are generally on short peduncles, broad often deeply bifid glumes with a hispid awn of varying length, and broadly ovoid turgid utricles, which are usually obscurely nerved. Kukenthal unites my var. *ochrosaccus* with the Norfolk Island *C. Neesiana*, placing it as *C. dissita* var. *Neesiana*. But a Norfolk Island specimen received many years ago from Baron Mueller does not support this view.

42. **C. Solandri** *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 284.—Densely tufted. Culms tall, slender, trigonous, slightly scabrid above, leafy, 1–3 ft. high, often elongating in fruit and becoming prostrate. Leaves long, narrow, keeled, $\frac{1}{10}$–⅙ in. broad; margins and keel sharply scabrid. Spikelets 5–10, distant, on long slender peduncles, long and narrow, ¾–2 in. long by about ⅛ in. broad, dark-brown; terminal 1–4 male, slender, usually closely placed; remainder all female, but generally with a few male flowers below, nodding, the 2 or 3 lowest often compound, on longer filiform peduncles; bracts long and leafy. Glumes broadly ovate, entire or bifid, membranous, dark or pale chestnut-brown; midrib produced into an awn of variable length. Utricles about equalling the glumes, ovoid,

turgid, unequally biconvex or obscurely trigonous, dark red-brown or purplish-black, rarely pale-brown, narrowed into a short sharply bidentate beak; margins smooth or serrate above. Styles 3. Nut ovoid, trigonous.—*Ill. Car.* i (1858) 61, t. 175; *Cheesem. Man. N.Z. Fl.* (1906) 832. C. dissita *var.* Neesiana *Kukenth. in Pflanzenr.* Heft 38 (1909) 691. C. Neesiana *Hook. f. Handb. N.Z. Fl.* (1864) 316; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 438 (*not of Endl.*).

North and South Islands, Stewart Island: Not uncommon from Ahipara and Mangonui southwards, usually in woods. Sea-level to 2000 ft. October–January.

Reduced to *C. dissita* by Kukenthal, as var. *Solandri*. No doubt there are transition states between the two plants—in the river valleys of north-west Nelson, for instance, where *C. Solandri* is particularly abundant, such may be commonly observed. But what I take to be the typical form is a much larger and more slender plant, with longer culms (sometimes over 5 ft. in length) that are often prostrate in fruit. The male spikelets (which are seldom more than one in *C. dissita*) are often as many as four or five; and the lower female spikelets are usually compound, with long nodding peduncles. These characters recede so much from the ordinary state of *C. dissita* that I cannot refuse to regard the two plants as distinct.

43. **C. ventosa** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 832.—Culms tall, robust, trigonous, 18 in. high, leafy at the base. Leaves equalling the culms or shorter than them, pale-green, smooth and glabrous, striate, flat, $\frac{1}{4}$ in. broad, sheathing at the base. Inflorescence 12–14 in. long; spikelets 6–8, $\frac{3}{4}$–3 in. long, pale; terminal 2–3 male, slender, approximate; remainder all female, erect, on long peduncles varying from $1\frac{1}{2}$–3 in. Utricles about $\frac{1}{8}$ in. long, elliptic-oblong, trigonous, narrowed at both ends, 12-nerved, stramineous; beak short. Nut elliptic-oblong, trigonous, black.—*C. B. Clarke in Kew Bulletin Additional Series*, xiii (1908) 83.

Chatham Islands: *H. H. Travers, W. R. B. Oliver!*

I have not seen authenticated specimens of this plant. Mr. C. B. Clarke, who communicated to me the brief notes upon which the above diagnosis has been based, considered that it should be placed in the vicinity of the Norfolk Island *C. Neesiana*; from which, however, it is removed by the larger and narrower utricle. For the present, I have associated with it a plant collected on the Chatham Islands by Mr. W. R. B. Oliver, specimens of which have been kindly lent to me by Mr. Petrie.

44. **C. longiculmis** *Petrie in Trans. N.Z. Inst.* xiv (1882) 363.—Tall, densely tufted. Culms terete or nearly so, smooth, 2–3 ft. high or more, leafy at the base. Leaves shorter than the culms or equalling them, pale-green, sheathing at the base, $\frac{1}{6}$–$\frac{1}{5}$ in. broad, flat or keeled, striate; margins slightly scabrid above. Spikelets 5–7, the lowermost usually distant, the remainder approximate; terminal one male, slender, 1–2 in. long, sometimes with a smaller one near its base; remainder all female, usually with a few male flowers at the base, rarely at the top, very large and stout, $\frac{3}{4}$–$1\frac{1}{2}$ in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, pale-brown, sessile or the lowest shortly peduncled; bracts leafy, far exceeding the inflorescence. Glumes broadly ovate, membranous, pale chestnut-brown, midrib produced into a stout hispid awn. Utricle equalling the glumes, somewhat stipitate, ovoid, biconvex, nerved, pale- or dark-brown, suddenly contracted into a rather long and stout bidentate beak; margins smooth. Styles 3. Nut trigonous.—*Cheesem. in Trans. N.Z. Inst.* xvi (1884) 438; *Man. N.Z. Fl.* (1906) 832; *Kukenth. in Pflanzenr.* Heft 38 (1909) 692.

Stewart Island: Paterson's Inlet, *Petrie! Thomson!* Glory Cove, *T. Kirk!*

A very distinct species, perhaps nearest to *C. litorosa*, but much larger in all its parts.

45. **C. Chathamica** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 55.—Culms 18–24 in. high, stout, smooth, erect, triquetrous. Leaves shorter than the culms, scarcely sheathing at the base, flat, smooth, $\frac{1}{4}$ in. broad or more, 3-nerved above, striate beneath with a conspicuous midrib, margins thickened and finely scabrid. Spikelets 7, simple or very rarely compound, 1–2$\frac{1}{2}$ in. long; the 3 uppermost male, slender, closely placed; the remainder female or with a few male flowers at the top, erect, distant, the lower ones with long peduncles. Bracts long, leafy. Glumes linear-lanceolate, acute or acuminate, membranous, produced into a short mucro, 1-nerved, chestnut-brown with a pale centre. Utricles shorter than the glumes, turgidly biconvex, strongly 2-nerved, dark-brown, smooth and shining, shortly stipitate, suddenly narrowed above into a short smooth bidentate beak. Styles 3.

Chatham Islands: Swampy ground; *W. R. B. Oliver!*

I have only seen two very indifferent specimens, for the loan of which I am indebted to Mr. Petrie.

46. **C. trifida** *Cav. Ic.* v (1799) 41, t. 465.—A very tall and stout species, forming dense tussocks 1–2 ft. diam. Culms stout, erect, 2–4 ft. high, obtusely trigonous, quite smooth, thickened at the base, copiously leafy. Leaves very large, overtopping the culms, 3–6 ft. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, sheathing at the base, keeled, rigid, striate; margins scabrid. Spikelets 6–12, very large and stout, 3–5 in. long, $\frac{1}{3}$–$\frac{2}{3}$ in. broad; upper 2–4 male, rather closely placed, sessile or nearly so; lower 4–6 female, farther apart, shortly stalked, the lowest often compound; bracts long, leafy. Glumes linear-oblong or lanceolate, deeply bifid, membranous, chestnut-brown; midrib produced into a long hispid awn. Utricle shorter than the glumes or almost equalling them, stipitate and attenuate at the base, oblong-obovoid, turgid, obsoletely trigonous, strongly nerved, rather abruptly contracted into a 2-toothed beak. Styles 3. Nut obovoid-oblong, trigonous. —*Raoul Choix* (1846) 40; *Hook. f. Fl. Antarct.* i (1844) 89; *Fl. Nov. Zel.* i (1853) 284; *Handb. N.Z. Fl.* (1864) 316; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 439; *Man. N.Z. Fl.* (1906) 833; *Kukenth. in Pflanzenr.* Heft 38 (1909) 731; *Cheesem. Vascl. Flora Macquarie Is.* (1919) 32. C. incrassata *Sol. ex Boott Ill. Car.* iv (1867) 138.

South Island: Marlborough—Queen Charlotte Sound, *Banks* and *Solander*. Canterbury—Akaroa, *Raoul*. Otago—Near Dunedin, *Buchanan! Lindsay, Petrie!* Bluff Hill, *T. Kirk!* Dusky Sound, *Lyall*. Stewart Island: *Petrie!* The Snares, Auckland and Campbell Islands, Antipodes Island, Macquarie Island: Not uncommon. *Sir J. D. Hooker, T. Kirk! A. Hamilton!* See Cavill Esc. e. 17 4:1935:111

Also in temperate South America, from Chile to Fuegia and the Falkland Islands. The large size, stout habit, and numerous massive spikelets readily distinguish it from any other species found in New Zealand.

47. **C. breviculmis** *R. Br. Prodr.* (1810) 242.—Culms short, tufted, erect or spreading from the base, 1–6 in. high. Leaves very much longer than the culms, spreading, $\frac{1}{20}$–$\frac{1}{12}$ in. broad, flat, grooved; margins slightly scabrid above. Spikelets 2–5, small, green, approximate, $\frac{1}{6}$–$\frac{1}{3}$ in. long; terminal one male; remainder all female, sometimes with male flowers at the top, erect, sessile or the lowest very shortly pedunculate; bracts long, narrow, leafy. Glumes laxly imbricate, ovate, pale-green, membranous; midrib stout, produced into a long hispid awn. Utricles shorter than the glumes, stipitate, narrow-elliptic, trigonous, faintly many-nerved, green, pubescent, narrowed upwards into a short pyramidal beak. Styles 3.

Nut elliptic-obovoid, trigonous; style-base dilated just above the top of the nut.—*Hook. f. Fl. Nov. Zel.* i (1853) 283, t. 63A; *Handb. N.Z. Fl.* (1864) 316; *Fl. Tasm.* ii (1860) 101; *Benth. Fl. Austral.* vii (1878) 445; *Boott Ill. Car.* iv (1867) 181; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 439; *Man. N.Z. Fl.* (1906) 833; *Kukenth. in Pflanzenr.* Heft 38 (1909) 469.

North and South Islands: Abundant from the North Cape to Foveaux Strait. Sea-level to 3000 ft. October–March.

Easily recognized by the small size and pubescent utricles. Also found in Australia and Tasmania, the Himalaya Mountains, China, and Japan.

48. **C. pumila** *Thunb. Fl. Jap.* (1784) 39.—Rhizome long, creeping, often many feet in length. Culms short, stout, 4–8 in. high, leafy throughout. Leaves much longer than the culms, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, rigid, keeled, grooved, glaucous-green, recurved above, tapering into long subulate points. Spikelets 3–6, approximate; terminal one male, slender, $\frac{3}{4}$–1 in. long, often with one or two much smaller ones near its base; remainder all female, sometimes with male flowers at the top, oblong, stout, $\frac{1}{2}$–$\frac{3}{4}$ in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad, sessile or the lowest shortly pedunculate; bracts long and leafy. Glumes ovate-oblong, membranous, chestnut-brown with pale hyaline margins; midrib stout, produced into a short awn or barely excurrent. Utricle very large, much exceeding the glumes, $\frac{1}{5}$–$\frac{1}{4}$ in. long, thick and corky, turgid, ovoid, smooth or obsoletely nerved, brown, narrowed into a short bidentate beak. Styles 3. Nut brown, ovoid, trigonous.—*Boott Ill. Car.* iv (1867) 217; *Hook. f. Handb. N.Z. Fl.* (1864) 315; *Benth. Fl. Austral.* vii (1878) 445; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 439; *Man. N.Z. Fl.* (1906) 834; *Kukenth. in Pflanzenr.* Heft 38 (1909) 738. C. littorea *Lab. Pl. Nov. Holl.* ii (1806) 69, t. 219; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 284.

var. macrocarpa Carse.

North and South Islands: Sandy shores from the North Cape to Foveaux Strait, abundant. October–January. See Trans. Roy. Soc. N.Z. 64: 1934: 111

Very distinct from any other New Zealand species. The long running rhizomes, glaucous keeled leaves, and large smooth and turgid utricles are conspicuous characters. Common in Australia and Tasmania, along the eastern coasts of Asia, and in extra-tropical South America. It is a useful plant in the reclamation of sand-dunes.

49. **C. Brownii** *Tuckerm. Enum. Car.* (1843) 21.—Culms tufted, slender, smooth, leafy at the base, 8–16 in. high. Leaves shorter than the culms, flat, grassy, $\frac{1}{8}$–$\frac{1}{6}$ in. broad; margins smooth or very slightly scabrid. Spikelets 3–4; terminal one male, small, $\frac{1}{5}$–$\frac{1}{2}$ in. long, slender, often few-flowered; remainder all female, $\frac{1}{3}$–$\frac{2}{3}$ in. long, about $\frac{1}{4}$ in. broad, dusky-brown, the two upper close together, on very short peduncles or subsessile, the third (when present) usually remote, on a slender erect peduncle sometimes 3 in. long; bracts leafy, rather short, but the upper exceeding the inflorescence. Male glumes narrow, membranous, terminating in a very long foliaceous awn. Female glumes with a small lanceolate or linear-oblong base ending in a serrulate awn equalling or shorter than the utricle. Utricles spreading when ripe, about $\frac{1}{8}$ in. long, broadly oblong or ovoid, turgid, obscurely trigonous, strongly nerved, dull-brown; beak very short, tipped with 2 pale-brown teeth. Styles 3. Nut obovoid-oblong, pale, trigonous.—*Boott Ill. Car.* iv (1867) 161, t. 532; *Benth. Fl. Austral.* vii (1878) 447; *Cheesem. Man. N.Z. Fl.* (1906) 834; *Kukenth. in Pflanzenr.* Heft 38 (1909) 612. C. striata *R. Br. Prodr.* (1810) 243 (*not of Michaux*).

North Island: Auckland — Marshes at Lake Tongonge, near Kaitaia, rare, *R. H. Matthews! H. Carse!*

An Australian plant, ranging from Queensland to Victoria; also found in Japan. Mr. Matthews, who is the first to observe it in New Zealand, considers it to be indigenous, and there is nothing improbable in its occurrence in the extreme north of the Dominion.

50. **C. Oederi** *Retz. Fl. Scand. Prodr.* (1779) 179; *var.* **cataractae** *Kukenth. in Pflanzenr.* Heft 38 (1909) 673. — Rhizome short, tufted. Culms tufted, smooth, trigonous with the angles somewhat acute, leafy, 2–8 in. high. Leaves usually longer than the culms in New Zealand specimens, yellow-green when dry, flat, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, spreading or recurved; margins slightly scabrid. Spikelets 3–8, yellow-green, closely approximate or rarely the lowest remote; terminal one (rarely two) male, slender, $\frac{1}{4}$–$\frac{3}{4}$ in. long; remainder all female but usually with a few male flowers at the top, ovoid or roundish, $\frac{1}{4}$–$\frac{1}{2}$ in. long, squarrose, sessile or the lowest sometimes peduncled; bracts long, leafy, spreading. Glumes ovate, obtuse, membranous; margins pale, sometimes hyaline. Utricles much exceeding the glumes, spreading or deflexed, ovoid, trigonous, inflated, strongly ribbed, pale yellow-green, suddenly narrowed into a long slender scabrid 2-toothed beak. Styles 3. Nut obovoid, trigonous.—C. cataractae *R. Br. Prodr.* (1810) 242; *Hook. f. Fl. Tasm.* ii (1860) 101, t. 151; *Handb. N.Z. Fl.* (1864) 315; *Boott Ill. Car.* iv (1867) 204. C. flava *Benth. Fl. Austral.* vii (1878) 444; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 439; *Man. N.Z. Fl.* (1906) 835.

South Island, Stewart Island: Mountain districts from Nelson southwards, usually in mountain-swamps. Generally from 1500 to 3500 ft., but descends to sea-level in Stewart Island and several scattered localities on the mainland. December–February.

It is quite an unsettled question whether the two plants known as *C. flava* and *C. Oederi* should be kept as distinct species or as varieties. In the first edition of this work I followed the opinion of Mr. C. B. Clarke in uniting them. *C. Oederi* mainly differs from *C. flava* in the smaller size and shorter nearly straight beak to the utricle. It is little more than a matter of taste as to how the two plants should be dealt with. Kukenthal's undoubted experience with both of them in the Northern Hemisphere, where they are plentiful, has mainly induced me to follow his views. The variety *cataractae* is not uncommon in the Southern Hemisphere, being known from New Zealand, Tasmania, South Africa, and temperate South America.

51. **C. vacillans** *Sol. ex Boott in Hook. f. Fl. Nov. Zel.* i (1853) 285.—Culms tufted, slender, weak, triquetrous with the angles scabrid, leafy, 10–18 in. high. Leaves longer or shorter than the culms, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, flat or keeled towards the base, striate, usually with a conspicuous nerve on each side of the stout midrib; margins and midrib beneath sharply scabrid. Spikelets 4–9, 1–3 in. long, about $\frac{1}{8}$ in. broad, bright red-brown; terminal 1–3 male, sometimes mixed with a few female flowers; remainder female, usually with a few male flowers at the base, the two or three lower ones remote, nodding, on long filiform peduncles, the upper ones closer together and on shorter stalks or subsessile; bracts long, leafy. Glumes ovate-lanceolate or oblong-lanceolate, entire, gradually narrowed into a short or rather long awn, red-brown; margins paler, often lacerate. Utricles usually longer than the glumes, stipitate, fusiform, triquetrous, conspicuously costate-nerved, red-brown, narrowed into a long slender beak with 2 acute teeth. Styles 3. Nut elliptic-oblong, whitish, trigonous. —*Boott Ill. Car.* iv (1867) 202; *Hook. f. Handb. N.Z. Fl.* (1864) 317; *Cheesem.*

in Trans. N.Z. Inst. xvi (1884) 440; *Man. N.Z. Fl.* (1906) 835; *Kukenth. in Pflanzenr.* Heft 38 (1909) 694. C. spinirostris *Col. in Trans. N.Z. Inst.* xv (1883) 335.

North Island: Not uncommon on declivities in dry woods, especially near the sea. October–November.

A very distinct species, easily recognized by the long and very slender red-brown spikelets, narrow entire glumes, and fusiform strongly ribbed long-beaked utricles.

52. **C. Cockayniana** *Kukenth. in Cheesem. Man. N.Z. Fl.* (1906) 836.—Culms slender, trigonous, smooth or slightly scabrid, leafy, 1–2 ft. high. Leaves usually longer than the culms, $\frac{1}{5}$–$\frac{1}{3}$ in. broad, flat, striate; margins scabrid above. Spikelets 5–8, $1\frac{1}{2}$–3 in. long, about $\frac{1}{4}$ in. broad, usually remote but sometimes the upper approximate, bright red-brown or pale-brown; terminal one male, generally with female flowers at the top, which sometimes occupy quite $\frac{1}{2}$ the spikelet; remainder all female, usually with male flowers at the base, all on filiform peduncles and nodding, or the upper almost sessile and erect; bracts long, leafy. Glumes ovate-lanceolate, entire or emarginate, membranous, red-brown; keel greenish, produced into a short awn. Utricles equalling the glumes or rather shorter than them, spreading when ripe, stipitate, narrow-elliptic, trigonous, strongly costate-nerved, pale yellow-brown, narrowed into a short stout minutely 2-toothed beak. Styles 3. Nut trigonous.—C. cinnamomea *Cheesem. in Trans. N.Z. Inst.* xiv (1882) 301 (*not of Olney*). C. Forsteri *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 440 (*in part*). C. Forsteri *var.* Cockayniana *Kukenth. in Pflanzenr.* Heft 38 (1909) 992.

South Island: Nelson—Graham River; sources of the Takaka River, *T. F. C.*; Mount Kelvin (near Westport), *W. Townson!* Westland—Kelly's Hill, *Petrie! Cockayne!* Franz Josef Glacier, *Cockayne.* Otago — Clinton Valley, *Petrie!* 500–4000 ft. November–January.

This differs from *C. vacilans* in the stouter habit, broader leaves, thicker spikelets, and broader and shorter utricles, which want the slender deeply bifid beak of that species. Kukenthal is now disposed to reunite it with *C. Forsteri.* As I have stated elsewhere, it is very much a matter of personal taste as to whether the two plants should be combined or kept apart. My own opinion is that the claims of *C. Cockayniana* to be regarded as distinct are quite as good as those of several species universally accepted.

53. **C. semi-Forsteri** *C. B. Clarke in Cheesem. Man. N.Z. Fl.* (1906) 836.—Culms tufted, stout, triquetrous, slightly scabrid above, 1–3 ft. high. Leaves numerous, usually longer than the culms, broad, $\frac{1}{5}$–$\frac{1}{3}$ in. diam. or even more, flat, coarsely ribbed or striate, often with a stout rib on either side of the midrib; margins and midrib beneath sharply scabrid. Spikelets 5–10, the lowermost distant, long-peduncled, simple or compound; the remainder more or less aggregated, the lower ones usually compound, the upper simple, 1–3 in. long, $\frac{1}{4}$–$\frac{1}{3}$ in. broad; terminal 1 or 2 male at the base; with the upper half or sometimes three-quarters female; the remainder all female, but usually with a few male flowers at the base; bracts very long and leafy. Glumes ovate-lanceolate, membranous, 3-nerved, pale ferruginous or whitish-green; midrib pale, produced into a short or long serrulate awn. Utricles longer or shorter than the glumes, narrowed at both ends, elliptic-oblong, trigonous, about 15–16-nerved; beak long, scabrid, with two somewhat spreading teeth.—*Kew Bulletin Additional Series,* viii (1908) 78. C. Forsteri *var.* insularis *Oliver in Trans. N.Z. Inst.* xlii (1910) 164. C. Kermadecensis *Petrie in Trans. N.Z. Inst.* xlvii (1915) 56.

KERMADEC ISLANDS: Apparently abundant in Sunday Island, *T. F. C.*, *Miss Shakespear!* *W. R. B. Oliver!* NORTH ISLAND: Mr. Clarke quotes "*Stephenson* n. 44, partim; *Hooker* n. 4189; *Colenso* n. 1622," but I have seen no specimens from the mainland of New Zealand that I can refer to the species. My statement in the Manual to the effect that the species is not uncommon in the North and South Islands is incorrect, and was due to a misapprehension of Mr. Clarke's correspondence.

54. **C. Forsteri** *Wahl. in Vet. Akad. Nya Handl. Stockh.* (1803) 154.—Culms tufted, stout or rather slender, trigonous, grooved, scabrid above, leafy, 1½–3 ft. high. Leaves longer or shorter than the culms, broad, ⅕–⅓ in. diam., flat, harsh, striate; margins and midrib beneath sharply scabrid. Spikelets 5–10, distant, 1½–3 in. long, ¼–⅓ in. broad, green or pale ferruginous; terminal 1–3 (usually 2) male, slender; remainder all female but commonly with male flowers either above or below, the upper 2–3 sessile or nearly so, the rest pedunculate, sometimes compound; bracts very long and leafy. Glumes ovate-lanceolate, membranous, ferruginous with a pale-green centre; midrib stout, produced into a short or rather long awn. Utricles equalling or exceeding the glumes, spreading when ripe, almost sessile or very shortly stipitate, elliptic-oblong or lanceolate-oblong, trigonous, nerved; beak ½–⅔ the length of the utricle, linear, with 2 lanceolate acute teeth. Styles 3. Nut obovoid-oblong, trigonous. — *Boott in Hook. f. Fl. Nov. Zel.* i (1853) 285; *Hook. f. Handb. N.Z. Fl.* (1864) 315 (*in part*); *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 440; *Man. N.Z. Fl.* (1906) 837; *Kukenth. in Pflanzenr.* Heft 38 (1909) 694. C. debilis *Forst. f. Prodr.* (1786) n. 550 (*name only*). C. punctulata *A. Rich. Fl. Nouv. Zel.* (1832) 119, t. 21.

NORTH AND SOUTH ISLANDS: Not uncommon from the Three Kings Islands and the North Cape southwards to Foveaux Strait. Sea-level to 2000 ft. November–January.

55. **C. pseudo-cyperus** *Linn. Sp. Plant.* (1753) 978. — Culms tufted, stout, triquetrous, scabrid on the angles, leafy, 1–3 ft. high. Leaves often longer than the culms, flat, broad, grassy, ⅓–½ in. diam.; margins scabrid. Spikelets 3–5, rarely more, usually clustered towards the top of the stem or the lowest one remote, 1–2½ in. long, pale-green; terminal one male, rarely female at the top, slender; remainder all female, long-peduncled and nodding, or in small specimens subsessile and erect, dense-flowered; bracts long, leafy. Glumes small, greenish-white, linear-oblong, suddenly narrowed into a stout serrulate awn. Utricles usually exceeding the glumes, spreading or even reflexed when ripe, stipitate, ovate-lanceolate, trigonous, somewhat inflated, strongly ribbed, greenish; beak ⅓–½ as long as the utricle, deeply split at the apex into two long and narrow almost pungent teeth. Styles 3. Nut small, obovoid, trigonous.—*R. Br. Prodr.* (1810) 243; *Boott Ill. Car.* iv (1867) 140, t. 451–52; *Benth. Fl. Austral.* vii (1878) 448; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 441; *Man. N.Z. Fl.* (1906) 837; *Kukenth. in Pflanzenr.* Heft 38 (1909) 695.

Var. **fascicularis** *Boott Ill. Car.* iv (1867) 141. — Rather taller and stouter. Spikelets 2–4 in. long, often pale red-brown when mature, farther apart and on longer peduncles, that of the lowest sometimes 4–8 in. long. Utricles broader and more truncate at the base, suddenly narrowed into a longer linear stalk; beak narrower.—*Kukenth. in Pflanzenr.* Heft 38 (1909) 696. C. fascicularis *Sol. in Hook. f. Fl. Nov. Zel.* i (1853) 283; *Fl. Tasm.* ii (1860) 101. C. Forsteri *var.* fascicularis *Hook. f. Handb. N.Z. Fl.* (1864) 315.

NORTH AND SOUTH ISLANDS: The species and variety not uncommon in swampy localities throughout. Sea-level to 3000 ft. November–February.

C. pseudo-cyperus, in its typical state, is plentiful in temperate and cool mountainous regions in most parts of the world; but the var. *fascicularis* exists only in New Zealand, Australia, and Tasmania. Kukenthal maintains, but as a "form" only, Boott's var. *minor*, ascribing to it Boeckeler's name of "*novae-seelandiae*." It only differs in its smaller size, fewer spikelets, and smaller utricles.

Family XIV. **PALMAE.**

Woody plants, usually with an erect stem bearing a terminal crown of large pinnate or fan-shaped leaves, rarely climbing or decumbent. Flowers regular, hermaphrodite or unisexual, small, numerous, arranged in spikes or panicles called spadices, which are enclosed when young within a large and broad deciduous bract called a spathe. Perianth inferior, coriaceous, persistent, of 6 segments in 2 series; the outer imbricate, often united into a 3-toothed or -lobed cup; the inner usually valvate. Stamens generally 6 or 3, rarely more, inserted at the base of the perianth; filaments free or connate, subulate or filiform; anthers versatile. Ovary superior, 1- or 3-celled, or of 3 distinct carpels; style very short or wanting; stigmas 3, sessile; ovules solitary (rarely 2) in each cell. Fruit a drupe or berry; exocarp thick, spongy, fleshy, or fibrous; endocarp membranous or crustaceous or bony. Seed with copious horny cartilaginous or oily albumen; embryo small, in a cavity near the surface of the albumen.

A majestic order, comprising nearly 130 genera and about 1100 species, almost wholly confined to tropical or warm extratropical regions, a few only found in northern or southern temperate latitudes. Few families are more generally useful, or applied to a greater variety of purposes. The timber, the foliage, the fruit, the starchy pith, and the fermentable sap are all employed. The coconut, date, sago-palm, cabbage-palm, betel-palm, African oil-palm, &c., are some of the best known species. The single genus found in New Zealand also occurs in Norfolk Island.

RHOPALOSTYLIS Wendl. and Drude. 1875

Stems tall, erect, unarmed, marked with annular scars. Leaves forming a terminal crown, pinnate; petiole long, furnished at the base with a long and broad sheathing part. Leaflets long, narrow, acuminate, slightly falcate at the apex, 3-costulate; secondary nerves several, distant; margins thin. Inflorescence at the base of the leaves, consisting of a much and densely branched spadix enclosed within two boat-shaped spathes of nearly equal size. Flowers monoecious, in glomerules of 3, a female in the centre, with a male on each side of it. Male flowers: Sepals subulate-lanceolate. Petals rather larger, obliquely ovate, acuminate, valvate. Stamens 6, free; filaments almost filiform, inflected at the tip; anthers linear-oblong, dorsifixed. Female flowers smaller and broader than the male, globose-ovoid; sepals broadly imbricate; petals convolute-imbricate at the base, valvate at the tips; ovary ovoid. Fruit small, elliptical or ovoid-oblong or almost globose, symmetrical; exocarp fleshy and succulent; endocarp fibrous within. Seed erect; albumen smooth, homogeneous. Embryo basal.

A genus consisting of three species, one of which is confined to New Zealand proper, another to the Kermadec Islands, while the third is restricted to Norfolk Island.

Stem slender, 15–30 ft. high. Seed ovoid-elliptical .. .. 1. *R. sapida.*
Stem stout, 30–60 ft. high. Seed globose .. .. .. 2. *R. Cheesemanii.*

1. **R. sapida** *Wendl. and Drude in Kerch. Palm.* 255.—Stem rather slender, smooth, 10–25 ft. high, 6–9 in. diam., rarely more. Leaves 4–8 ft. long; rhachis clothed with copious lepidote scales; leaflets very numerous, 2–3 ft. long or more, 1–2 in. broad, linear-ensiform, midrib and main veins covered with lepidote scales; margins replicate at the base. Spadix 1–2 ft. long, much and closely branched, glabrous; spathes 2 or 3. Flowers very densely crowded, purplish-lilac. Drupe ½ in. long, elliptic-oblong, bright-red. —*Cheesem. Man. N.Z. Fl.* (1906) 740. Areca sapida *Soland. ex Forst. f. Pl. Escul.* (1786) 66; *A. Rich. Fl. Nouv. Zel.* (1832) 157; *A. Cunn. Precur.* (1836) n. 298; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 262, tt. 59, 60; *Handb. N.Z. Fl.* (1864) 288; *Bot. Mag.* t. 5139. Kentia sapida *Mart. Hist. Palm.* iii (1823) 312.

North Island: Abundant in forests throughout, except in the central mountainous portion. South Island: In lowland districts not far from the coast as far south as Banks Peninsula and Hokitika, rare and local. Chatham Islands: *F. A. D. Cox!* Sea-level to 2000 ft. *Nikau.* January–April.

The nikau-palm, so well known to all residents in the northern half of the Dominion, is of special interest as being the most southern member of its family. The unexpanded central bud and the very young spadix are both edible, and were formerly eaten by the Maoris, and even by European settlers. Branched specimens are occasionally seen; a very remarkable one with no less than 11 branches has been described and figured by Mr. Percy Smith (Trans. N.Z. Inst. x (1878) 357, t. 15). Two others are figured by myself in vols. xxxix (1907) and xlii (1910) of the same publication.

2. **R. Cheesemanii** *Beccari in Trans. N.Z. Inst.* xlix (1917) 47.—A noble palm with a rather stout stem 30–60 ft. in height, and a trunk over 12 in. diam. Primordial leaves with the blade 5–8 in. long, deeply bifid, or formed by two lanceolate leaflets united by their bases. Adult leaves pinnate; leaflets narrow-ensiform, acuminate, green above, subglaucescent beneath, distinctly 3-costulate; midrib and main veins more or less covered with brownish scales. Spadix 2 ft. long or even more, much branched; the branches thick and angular. Fruit globose, ⅓–½ in. diam.; exocarp slightly fleshy; endocarp thin, cartilaginous, closely enveloping the seed. Seed globose; outer coat light-coloured and almost polished.—R. Baueri *Cheesem. in Trans. N.Z. Inst.* xx (1888) 174; *Man. N.Z. Fl.* (1906) 740 (*not of Wendl. and Drude*); *Cockayne Veg. N.Z.* (1921) t. 84.

Kermadec Islands: Sunday Island, abundant from sea-level to the tops of the hills, altitude 1500 ft., *T. F. C., Miss Shakespear! W. R. B. Oliver!*

Family XV. **LEMNACEAE.**

Minute gregarious floating water-plants, without distinct stems or true leaves, consisting of green scale-like fronds free from one another or 2–3 cohering by their margins, either rootless or more generally giving off 1 or several capillary rootlets from the under-surface. Flowers very seldom produced, most minute, placed in clefts on the edges of the frond, or sunk on its surface, naked or enclosed in a spathe, usually a single female with 1 or 2 males by its side. Perianth wanting in both sexes. Male flower: Stamens 1 or 2; filaments short; anthers 1–2-celled. Female: Ovary sessile, 1-celled, narrowed into a short and stout style; stigma simple; ovules 1–7. Fruit a somewhat fleshy utricle, with 1 or several seeds; albumen fleshy or wanting; embryo straight, axile.

An order of 2 genera and 20 species, found in still waters in all countries, both temperate and tropical. It contains the smallest of all known flowering-plants, all of them being of exceedingly simple structure, and very seldom found in flower.

L. oligorrhiza Trans. 60: 563. & 65: 3.

1. **LEMNA** Linn. 1735.

Fronds proliferous from the sides near the base, with one or several delicate root-fibres descending from the under-surface. Flowers in marginal clefts of the fronds. Filaments slender; anthers didymous, 2-celled; pollen globose, muricate. Ovary with 1–7 ovules. Fruit a 1–7-seeded utricle. Seeds erect or horizontal; embryo conic or ovoid.

A small genus of 8 or 9 species, most of them of almost world-wide distribution. The two following are all that are positively known to occur in New Zealand, but others will probably be found.

Root single. Fronds broadly ovate, thin, almost flat on both surfaces. Ovule solitary	1. *L. minor.*
Root single. Fronds broadly ovate, thick, conspicuously tumid beneath. Ovules 2	2. *L. gibba.*

Ex ? 1. **L. minor** *Linn. Sp. Plant.* (1753) 970.—Root solitary, the sheath at its base without appendages. Frond symmetrical, $\frac{1}{8}$–$\frac{1}{4}$ in. long, ovate or oblong, nearly flat on both surfaces, green above, paler beneath; young ones growing from one side but soon becoming disconnected. Spathe unequally 2-lipped. Stamens 2, appearing successively (each a distinct male flower). Style rather long. Seed horizontal, hemi-anatropal, albuminous.—*Hook. f. Fl. Nov. Zel.* i (1853) 239; *Handb. N.Z. Fl.* (1864) 278; *Benth. Fl. Austral.* vii (1878) 163; *Hegelm. Lemn.* (1868) 142, t. 9, 10.

North and South Islands: Still waters, abundant throughout. Sea-level to 2000 ft. *Duckweed.* Almost cosmopolitan in its distribution.

Ex ? 2. **L. gibba** *Linn. Sp. Plant.* (1753) 970.—Root solitary, the sheath at its base elongate, cylindric, rootcap acute. Frond symmetrical, $\frac{1}{4}$–$\frac{1}{3}$ in. long, thick and spongy, flat above, convex beneath; young ones growing from one side, but soon separating. Spathe sac-like. Stamens 2. Ovules 2 or more. Utricle bursting transversely. Seeds erect, anatropous; albumen scanty or wanting.—*Hook. f. Fl. Nov. Zel.* i (1853) 239; *Handb. N.Z. Fl.* (1864) 278; *Benth. Fl. Austral.* vii (1878) 163; *Hegelm. Lemn.* (1868) 145, tt. 11–13.

North Island: Poverty Bay, *Colenso.*

I have seen no New Zealand specimens of this species, which is almost as widely distributed as *L. minor.* It is recognized at a glance by the conspicuously tumid under-surface of the frond.

RESTIONACEAE

Family XVI. **RESTIACEAE.**

Sedge-like or rush-like perennial herbs, either tufted or with a creeping rhizome usually covered with imbricated scales. Stems rigid, simple or branched, erect or flexuose. Leaves either few, radical, linear and sedge-like, or more often nearly or altogether reduced to convolute scales sheathing the stem; sheaths usually split to the base. Flowers dioecious, very rarely hermaphrodite, in spikes or racemes or panicles, each flower furnished at the base with a dry and rigid bract (glume) and sometimes 2 bracteoles. Perianth regular, of 6, rarely more or less, rigid or scarious erect segments. Male flowers: Stamens 3; filaments free or rarely connate into a colmun; anthers oblong, usually 1-celled. Rudimentary ovary occasionally present. Female flowers: Staminodia present or absent. Ovary 1–3-celled; styles as many as the cells, free or connate at the base,

stigmatic on the inner side; ovules solitary in each cell, pendulous, orthotropous. Fruit either a 1–3-celled capsule with longitudinal dehiscence or an indehiscent nut. Seeds 1 in each cell, pendulous, albumen farinaceous; embryo small, remote from the hilum.

A small order of about 20 genera and 230 species, almost confined to South Africa and Australia, the only species found outside these countries being the three occurring in New Zealand, one in Chile, and one in Cochin-China. The species have no important uses or properties.

Spikelets many-flowered, panicled. Ovary 3-celled. Fruit 3-angled, dehiscing at the angles	1. LEPYRODIA.
Spikelets many-flowered, panicled. Ovary 1-celled. Nut 3-angled, indehiscent	2. LEPTOCARPUS.
Spikelets few-flowered, female 1-flowered. Ovary 1-celled. Nut ovoid, terete, smooth	3. HYPOLAENA.

SPORADANTHUS F. Muell. ex Benth. Trans. 6:1874:340 & 10:44.41

1. LEPYRODIA R. Br. 1810

Rhizome stout, creeping, scaly. Stems erect, simple or branched, terete. Leaves reduced to persistent or rarely deciduous sheathing scales. Flowers dioecious or monoecious, rarely hermaphrodite, in rather broad or narrow panicles, sometimes almost spicate, the inflorescence not conspicuously different in the two sexes. Glumes lanceolate, scarcely imbricate; bracteoles 2 at the base of each flower. Male flowers: Perianth-segments 6, glume-like or thin and almost hyaline. Stamens 3; filaments distinct; anthers 1-celled. Female flowers: Perianth as in the males. Staminodia 3, sometimes with abortive anthers. Ovary 3-angled, 3-celled; styles 3, free or connate at the base; ovules 1 in each cell. Capsule triquetrous, dehiscing at the angles.

1. **L. Traversii** *F. Muell. Fragm.* viii (1873) 79.—Rhizome stout, creeping, clothed with pale-chestnut scales; roots long, stringy. Stems stout, terete, polished, simple below, fastigiately branched above, 2–5 ft. high. Sheaths distant, closely appressed, acuminate, ¾–1 in. long. Inflorescence a rather narrow closely branched red-brown terminal panicle 2–5 in. long; branches erect, unequal; bracts under the branches rigid, lanceolate, acuminate. Flowers sessile or shortly pedicelled within lanceolate glumes rather longer than the perianth; 2 scarious bracteoles at the base of each flower. Perianth-segments in both sexes red-brown, lanceolate, acute; male flowers with a small rudimentary ovary, females with 3 slender staminodia. Anthers linear-oblong, minutely apiculate. Ripe fruit 1-celled, 1-seeded, obliquely ovoid, triquetrous with the angles thickened, tipped with the remains of the style, at length dehiscent along the angles.—*Cheesem. Man. N.Z. Fl.* (1906) 760; *Ill. N.Z. Fl.* ii (1914) t. 208. Calorophus sp. *Hook. f. Fl. Nov. Zel.* i (1853) 267. Sporadanthus Traversii *F. Muell. in Trans. N.Z. Inst.* vii (1875) 389; *T. Kirk ibid.* x (1878) App. 41.

(Mem.)

1. **L. simplex** *A. Rich. Fl. Nouv. Zel.* (1832) 142 (*not of R. Br.*).—Rhizome stout, creeping, clothed with chestnut-brown scales. Stems numerous, densely crowded, simple, slender, terete, rush-like, 1–5 ft. high. Sheaths closely appressed, blackish-brown, distant, 1½–4 in. apart. Male inflorescence panicled; panicles variable in size, sometimes long and slender, at other times short and contracted, alternate on the upper part of the stem. Spikelets numerous, sessile or pedicelled, red-brown, ¼–½ in. long, many-flowered. Glumes imbricate, ovate-lanceolate, acuminate, much longer than the flowers. Perianth-segments 4–6, lanceolate, the 3 inner rather smaller. Female inflorescence compacted into rounded or oblong often lobed or interrupted fascicles or glomerules, alternate along the stem. Glumes broadly ovate, acuminate. Perianth rather longer than in the males; segments 6, the 3 outer keeled, acuminate; the 3 inner flat, oblong, obtuse or mucronate. Fruit narrow-ovoid, triquetrous.—*A. Cunn. Precur.* (1836) n. 291; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 265, t. 61; *Handb. N.Z. Fl.* (1864) 294; *Cheesem. Man. N.Z. Fl.* (1906) 761. Restio simplex *Murr. Syst. Veg.* v (1744) 882; *Forst. f. Prodr.* (1786) n. 367.

Ed. 13 — 725 (1784)

North and South Islands, Stewart Island, Chatham Islands: Salt marshes and sandy shores, abundant. Also inland near hot springs at Rotorua and at Tokaanu (Lake Taupo). *Oioi.* September–December.

CALOROPHUS Labill. Pl. Nov. Holl. ii (1806) 78 t. 228

3. **HYPOLAENA** R. Br. 1810 Kew Bull 1940 p. 92

Stems slender, much branched, often flexuous. Leaves reduced to persistent sheathing scales. Flowers dioecious, in spikelets with imbricate glumes and no bracteoles; the male spikelets few- or many-flowered, rarely 1-flowered, solitary or 2 together along the branchlets, or several in a terminal panicle; the females 1-flowered, either solitary or 2–3 together near the tips of the branches. Male flowers: Perianth-segments 6, narrow, thin. Stamens 3; filaments filiform; anthers 1-celled. Female flowers: Perianth-segments 6, smaller than in the males, very thin, almost hyaline. Staminodia when present 3. Ovary 1-celled; style-branches 2 or 3, filiform; ovule solitary, pendulous. Fruit an ovoid or obovoid terete indehiscent 1-seeded nut.

A genus consisting of about 25 species natives of South Africa, and 5 found in Australia, one of the latter extending to New Zealand.

SPORADANTHUS F. Muell. Fragm. Trans. 6:1874:340
4 10 : 44. 41

1. LEPYRODIA R. Br. 1810

Rhizome stout, creeping, scaly. Stems erect, simple or branched, terete. Leaves reduced to persistent or rarely deciduous sheathing scales. Flowers dioecious or monoecious, rarely hermaphrodite, in rather broad or narrow panicles, sometimes almost spicate, the inflorescence not conspicuously different in the two sexes. Glumes lanceolate, scarcely imbricate; bracteoles 2 at the base of each flower. Male flowers: Perianth-segments 6, glume-like or thin and almost hyaline. Stamens 3; filaments distinct; anthers 1-celled. Female flowers: Perianth as in the males. Staminodia 3, sometimes with abortive anthers. Ovary 3-angled, 3-celled; styles 3, free or connate at the base; ovules 1 in each cell. Capsule triquetrous, dehiscing at the angles.

1. **L. Traversii** *F. Muell. Fragm.* viii (1873) 79.—Rhizome stout, creeping, clothed with pale-chestnut scales; roots long, stringy. Stems stout, terete, polished, simple below, fastigiately branched above, 2–5 ft. high. Sheaths distant, closely appressed, acuminate, ¾–1 in. long. Inflorescence a rather narrow closely branched red-brown terminal panicle 2–5 in. long; branches erect, unequal; bracts under the branches rigid, lanceolate, acuminate. Flowers sessile or shortly pedicelled within lanceolate glumes rather longer than the perianth; 2 scarious bracteoles at the base of each flower. Perianth-segments in both sexes red-brown, lanceolate, acute; male flowers with a small rudimentary ovary, females with 3 slender staminodia. Anthers linear-oblong, minutely apiculate. Ripe fruit 1-celled, 1-seeded, obliquely ovoid, triquetrous with the angles thickened, tipped with the remains of the style, at length dehiscent along the angles.—*Cheesem. Man. N.Z. But in young buds I can find no trace of the ovary being 3-celled, or of there being more than one ovule. I think that ultimately Mueller's view will be substantiated.

2. LEPTOCARPUS R. Br. 1810

Stems simple or branched, terete, erect from a stout creeping scaly rhizome. Leaves reduced to persistent sheathing scales. Flowers dioecious, the spikelets with imbricate glumes with or without bracteoles, the male and female inflorescences alike or dissimilar, sometimes both sexes have the spikelets arranged in panicles, sometimes the male spikelets are pedicelled and paniculate, and the females sessile and fascicled or spicate. Male flowers: Perianth-segments 6. Stamens 3; filaments filiform; anthers 1-celled. Female flowers: Perianth as in the males. Staminodia 3 or none. Ovary 1-celled, triquetrous; styles 3, filiform; ovule solitary, pendulous. Fruit narrow-ovoid, triquetrous, indehiscent or splitting down the angles.

Species about 25, one in New Zealand, one in Chile, another in Cochin-China, 7 in South Africa, the remainder confined to Australia.

1. **L. simplex** *A. Rich. Fl. Nouv. Zel.* (1832) 142 (*not of R. Br.*).—Rhizome stout, creeping, clothed with chestnut-brown scales. Stems numerous, densely crowded, simple, slender, terete, rush-like, 1–5 ft. high. Sheaths closely appressed, blackish-brown, distant, 1½–4 in. apart. Spikelets numerous, sessile or pedicelled, red-brown, ¼–½ in. long, many-flowered. Glumes imbricate, ovate-lanceolate, acuminate, much longer than the flowers. Perianth-segments 4–6, lanceolate, the 3 inner rather smaller. Female inflorescence compacted into rounded or oblong often lobed or interrupted fascicles or glomerules, alternate along the stem. Glumes broadly ovate, acuminate. Perianth rather longer than in the males; segments 6, the 3 outer keeled, acuminate; the 3 inner flat, oblong, obtuse or mucronate. Fruit narrow-ovoid, triquetrous.—*A. Cunn. Precur.* (1836) n. 291; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 265, t. 61; *Handb. N.Z. Fl.* (1864) 294; *Cheesem. Man. N.Z. Fl.* (1906) 761. Restio simplex *Murr. Syst. Veg.* v (1744) 882; *Forst. f. Prodr.* (1786) n. 367.

North and South Islands, Stewart Island, Chatham Islands: Salt marshes and sandy shores, abundant. Also inland near hot springs at Rotorua and at Tokaanu (Lake Taupo). *Oioi.* September–December.

3. HYPOLAENA R. Br. 1810

Stems slender, much branched, often flexuous. Leaves reduced to persistent sheathing scales. Flowers dioecious, in spikelets with imbricate glumes and no bracteoles; the male spikelets few- or many-flowered, rarely 1-flowered, solitary or 2 together along the branchlets, or several in a terminal panicle; the females 1-flowered, either solitary or 2–3 together near the tips of the branches. Male flowers: Perianth-segments 6, narrow, thin. Stamens 3; filaments filiform; anthers 1-celled. Female flowers: Perianth-segments 6, smaller than in the males, very thin, almost hyaline. Staminodia when present 3. Ovary 1-celled; style-branches 2 or 3, filiform; ovule solitary, pendulous. Fruit an ovoid or obovoid terete indehiscent 1-seeded nut.

A genus consisting of about 25 species natives of South Africa, and 5 found in Australia, one of the latter extending to New Zealand.

C. lateriflorus (R.Br.) F.v.M.

1. **H. lateriflora** *Benth. Fl. Austral.* vii (1878) 238. — Stems slender, much branched, flexuose and often interlacing, usually from 9–18 in., but sometimes forming dense masses 2–3 ft. high. Sheaths $\frac{1}{5}$–$\frac{1}{3}$ in. long, closely appressed, often ciliate at the mouth, with a short subulate spreading tip. Male spikelets 1 or 2 together in the upper sheaths, each spikelet 3–6-flowered; glumes rather thin, rigid, tip acute. Perianth-segments 6, very narrow-linear, acute. Stamens 3; anthers linear-oblong. Female spikelets solitary within the uppermost sheaths, 1–3-flowered. Perianth-segments 6 or 4, very small, the inner not much longer than the ovary, broadly ovate, thin and hyaline. Style-branches 3. Nut broadly ovoid, terete, with a thick and swollen base.—*Cheesem. Man. N.Z. Fl.* (1906) 761. Calorophus elongatus *Lab. Pl. Nov. Holl.* ii (1806) 78, t. 228 (*in part*); *Hook. f. Fl. Nov. Zel.* i (1853) 267; *Handb. N.Z. Fl.* (1864) 297.

Var. **minor** *Hook. f. Handb. N.Z. Fl.* (1864) 297.—Much smaller and more slender, sometimes only a few inches high. Male spikelet solitary, 2–3-flowered; female usually 1-flowered.—Calorophus minor *Fl. Nov. Zel.* i (1853) 267.

North and South Islands, Stewart Island, Chatham Islands: The typical form not uncommon in lowland swamps in the North Island, from the North Cape southwards; var. *minor* abundant in mountain districts throughout. Sea-level to 5500 ft. November–March.

Also an abundant Australian and Tasmanian plant. The var. *minor* passes insensibly into the ordinary form.

see Pl. Hamiltonian. 15a. p. 32. 1930.

Family XVII. **CENTROLEPIDACEAE.**

Annual or perennial tufted often moss-like plants, of small size. Leaves linear or setaceous, either all radical or densely imbricated on the short stems and branches. Flowers very small, usually hermaphrodite, one or several within 1–3 bracts, forming little heads or spikelets terminating short scapes or peduncles. Bracteoles or glumes under each flower 1–3, hyaline, sometimes wanting. Perianth none. Stamens 1–2; filaments filiform; anthers versatile, 1-celled. Ovary either 1-celled, or with 2–3 collateral cells, or of 2 or more free or irregularly connate carpels superposed in 2 rows; ovules solitary and pendulous in each cell or carpel; styles as many as the cells or carpels; stigmas linear. Fruit small, dry, pericarp membranous, the cells or carpels opening extrorsely by a longitudinal slit. Seed pendulous or laterally affixed; albumen farinaceous; embryo minute.

A small and inconspicuous order, comprising 4 or 5 genera and about 35 species. With the exception of the New Zealand species, one found in China, and one in antarctic South America, the order is confined to Australia. It has no properties of importance.

Flowers crowded in terminal heads enclosed within 2–5 bracts; heads unisexual .. .. 1. Hydatella.
Flowers within 2 alternate bracts, 1–5 within each bract. Stamen 1. Ovary of 3 or more carpels superposed in 2 rows (rarely reduced to 1) .. .. 2. Centrolepis.
Flowers within 2–3 alternate bracts, 1 or rarely 2 within each bract. Stamen 1 to each flower. Ovary of 2 collateral cells or carpels .. 3. Gaimardia.

1. **HYDATELLA** Diels. 1904

Minute tufted and stemless annual herbs. Leaves numerous, all radical, filiform. Scapes usually numerous, radical, shorter than the leaves, each bearing a terminal head of minute flowers enclosed within 2–5 bracts; heads unisexual. Bracts usually 2 in the Australian species, 3–5 in the New

Zealand. Male flowers: Stamens with a filiform filament and a 2-celled oblong anther. Female flowers: Ovaries densely crowded within the bracts, numerous, oblong or ovoid, not angled nor compressed, 1-celled and 1-ovuled; styles numerous, filiform, elongated, unequal in length. Fruit oblong or elliptic-ovoid, apparently indehiscent.

A genus of three species; two found in West Australia, the third endemic in New Zealand. It is closely allied to *Juncella* F. Muell. (*Trithuria* Hook. f.), but differs in the inflorescence being monoecious, in the stipitate flowers, in the longer and more numerous styles, and in the bracts being usually 3–5.

1. **H. inconspicua** *Cheesem. in Trans. N.Z. Inst.* xxxix (1907) 433.—A very minute slender perfectly glabrous annual herb, forming dense moss-like tufts ½–1 in. high. Leaves numerous, all radical, filiform, strict, erect, terete, gradually tapering to an acute point. Scapes very short in the flowering stage, lengthening to ½ or ¾ the length of the leaves when in fruit. Bracts 3–5, erect or erecto-patent, linear-lanceolate to ovate-lanceolate, acute, thin and membranous, $\frac{1}{12}$–$\frac{1}{8}$ in. long. Heads unisexual; males not seen. Ovaries densely crowded within the bracts, usually from 10 to 20, shortly stipitate, ovoid or oblong-ovoid, smooth, pale yellow-brown or reddish. Styles numerous, very delicate, forming a spreading brush at the tip of the ovary, and often much longer than it. Ripe fruit elliptic-ovoid, pale yellow-brown with a dark spot at each end.—Trithuria inconspicua *Man. N.Z. Fl.* (1906) 754.

North Island: Auckland—Sandy shores of Lake Ngatu, coast north of Ahipara, North Cape district, *H. Carse* and *R. H. Matthews!* Lake Rotoroa, in the same district, *H. B. Matthews!*

A very curious and remarkable little plant, so far only known from the locality quoted above. It is clearly congeneric with the two Australian species, which have been excellently described and figured by Dr. Diels in his "Fragmenta Phytographiae Australiae Occidentalis," but differs from them in the stricter and more densely tufted habit, and more numerous bracts.

2. **CENTROLEPIS** Labill.

Small tufted annual or perennial herbs. Leaves all radical or imbricating along the stems, linear or filiform. Scape slender, terminating in 2 floral bracts which are either subopposite or one a little above the other. Flowers hermaphrodite, sessile, from 1 to 5 within each bract; each flower with 1–3 hyaline scales, or rarely the scales altogether wanting. Stamen 1; filament very long, filiform; anther linear-oblong, 1-celled. Carpels from 3–8 (sometimes reduced to 1), connate and superposed in 2 rows; styles as many as the carpels, filiform, free or connate at the base. Fruiting-carpels with a membranous pericarp, longitudinally dehiscent.

A small genus of between 20 and 30 species, all confined to Australia, except one found in Cambodia, and the New Zealand plant, which is much more widely distributed in Australia than in New Zealand.

1. **C. strigosa** *Roem and Schult. Syst.* i (1817) 43.—A slender tufted annual herb 1–2 in. high. Leaves all radical, much shorter than the scapes, expanded into a broad membranous sheathing base below, above very narrow-linear or filiform, hispid throughout with short spreading hairs. Scapes radical, slender, hispid like the leaves. Floral bracts 2, close together, ovate, awned at the tip, concave, spreading, hispid with long hairs. Flowers from 3 to 8 within each bract, each flower with 3 hyaline scales, the scales unequal in length, the largest one usually as long as the bract, the others

shorter. Stamen 1, exserted. Carpels from 3 to 8 in each flower, superposed and connate in 2 rows; styles as many as the carpels, free almost to the base.—*Benth. Fl. Austral.* vii (1878) 207; *T. Kirk in Trans. N.Z. Inst.* xxiii (1891) 442; *Cheesem. Man. N.Z. Fl.* (1906) 756.

SOUTH ISLAND: Otago—Bluff Hill, *T. Kirk! H. J. Matthews!* December–January.

A common Australian and Tasmanian plant.

3. GAIMARDIA Gaud. 1826.

Densely tufted perennial herbs, forming moss-like patches in subalpine bogs. Stems much branched, leafy throughout. Leaves numerous, densely imbricated, linear or linear-subulate or setaceous, erect, dilated at the base into broad membranous sheaths. Scape terminal, shorter or slightly longer than the leaves. Floral bracts 2 or 3, when 3 the upper one usually empty. Flowers 1, or more rarely 2 to each bract. Stamen 1 to each flower, sometimes deficient in one of the flowers. Ovary 2-celled or more rarely 3-celled, the cells (or carpels) collateral, connate; styles the same number as the carpels, long, filiform. Fruiting carpels 2, or 1 by abortion.

In my memoir on the botany of the Subantarctic islands of New Zealand I have transferred to *Gaimardia* three plants (*G. ciliata*, *G. pallida*, and *G. minima*) placed by Kirk in *Centrolepis*. As pointed out in the first edition of this work, they differ in the perennial densely pulvinate habit, the shape of the leaves, the flowers seldom more than 1 in each floral bract, and in the cells of the ovary (or carpels) being frequently reduced to 1. In the "Pflanzenfamilien" Hieronymus keeps up the genus *Alepyrum* for their reception, a course which is likely to lead to confusion, seeing that not one of the species which R. Brown placed in the original genus *Alepyrum* is retained in it by Hieronymus. Until the whole family receives a careful examination it is best to leave the species in *Gaimardia*.

As now constituted *Gaimardia* is a genus containing 5 species, 4 of which are natives of New Zealand, the remaining 1 being endemic in Fuegia.

1. *Glabrous.*	
Minute; stems $\frac{1}{4}$–$\frac{1}{2}$ in. high. Carpels 2–5 to each flower ..	1. *G. minima.*
Larger; stems $\frac{3}{4}$–1 in. high, forming compact patches. Carpels 1–3 to each flower	2. *G. pallida.*
Forming broad patches 1–3 ft. across. Leaves with acicular tips. Carpels 1–2 to each flower	3. *G. setacea.*
2. *Sheaths densely ciliate.*	
Forming patches 1–4 ft. across and often 2 in. thick. Carpels usually 1 to each flower	4. *G. ciliata.*

1. **G. minima**, *Cheesem.* — A minute glabrous densely tufted plant, forming flat moss-like patches. Stems very short, $\frac{1}{4}$–$\frac{1}{2}$ in. high. Leaves equalling or rather shorter than the scapes, distichous, linear-subulate, dilated into broad equitant membranous sheaths at the base. Scape short, stout. Floral bracts 2, opposite, ovate, erect, the outer one shortly awned. Flowers 1 to each bract, one of them with a stamen, the other usually without, filament very long. Hyaline scales wanting. Carpels from 2 to 5 to each flower, connate in 2 rows; styles as many as the carpels, connate at the base.—Centrolepis minima *T. Kirk in Trans. N.Z. Inst.* xxiii (1891) 441; *Cheesem. Man. N.Z. Fl.* (1906) 757.

SOUTH ISLAND: Westland—Shores of Lake Brunner, *T. Kirk!* Otago—Lake Te Anau, *Petrie!* January–March.

Very closely allied to *G. pallida*, but a smaller, stiffer plant, with more numerous carpels to the flowers.

Alepyrum pallidum etc

2. **G. pallida** *Hook. f. Fl. Antarct.* i (1844) 86.—Forming pale-green cushion-shaped masses. Stems short, densely packed, $\frac{1}{2}$–$1\frac{1}{2}$ in. high, leafy throughout. Leaves closely imbricate, distichous, $\frac{1}{6}$–$\frac{1}{3}$ in. long; sheaths $\frac{1}{2}$ the length of the leaf or more, white and transparent, membranous, glabrous; lamina laterally compressed, ensiform-lanceolate or subulate, acute. Scape terminal, usually shorter than the leaves. Floral bracts 2, close together, unequal, the lower one the largest. Flowers 2, the upper one always with a stamen, the lower one frequently without; filament very long, the anther far-exserted. Ovary of 1–3 (rarely 4) superimposed and connate carpels; styles as many as the carpels, connate at the base.—Alepyrum pallidum *Fl. Nov. Zel.* i (1853) 268, t. 62c; *Handb. N.Z. Fl.* (1864) 296. Centrolepis pallida *Cheesem. Man. N.Z. Fl.* (1906) 757.

NORTH ISLAND: Boggy places near the base of Tongariro and Ruapehu, *T. F. C., Cockayne;* Ruahine Mountains, *Colenso.* SOUTH ISLAND: Otago—Maungatua, Mount Kyeburn, Clinton Valley, Blue Mountains, *Petrie!* CAMPBELL ISLAND: *Hooker, T. Kirk! R. M. Laing!* December–March.

3. **G. setacea** *Hook. f. Fl. Nov. Zel.* i (1853) 267.—Perennial, densely tufted and compacted, forming broad moss-like patches sometimes 1–3 ft. across. Stems very numerous, branched, erect, leafy throughout, 1–3 in. high. Leaves numerous, erect, densely imbricate, $\frac{1}{4}$–$\frac{3}{4}$ in. long, linear-setaceous with acicular tips; sheaths broad, membranous, quite glabrous, entire, produced at the tip into a free ligule. Scape terminal, rigid, erect, longer than the leaves. Floral bracts 2 or 3, alternate, convolute, appressed

2. **G. pallida** *Hook. f. Fl. Antarct.* i (1844) 86.—Forming pale-green cushion-shaped masses. Stems short, densely packed, ½–1½ in. high, leafy throughout. Leaves closely imbricate, distichous, ⅙–⅓ in. long; sheaths ½ the length of the leaf or more, white and transparent, membranous, glabrous; lamina laterally compressed, ensiform-lanceolate or subulate, acute. Scape terminal, usually shorter than the leaves. Floral bracts 2, close together, unequal, the lower one the largest. Flowers 2, the upper one always with a stamen, the lower one frequently without; filament very long, the anther far-exserted. Ovary of 1–3 (rarely 4) superimposed and connate carpels; styles as many as the carpels, connate at the base.—Alepyrum pallidum *Fl. Nov. Zel.* i (1853) 268, t. 62c; *Handb. N.Z. Fl.* (1864) 296. Centrolepis pallida *Cheesem. Man. N.Z. Fl.* (1906) 757.

North Island: Boggy places near the base of Tongariro and Ruapehu, *T. F. C., Cockayne;* Ruahine Mountains, *Colenso.* South Island: Otago—Maungatua, Mount Kyeburn, Clinton Valley, Blue Mountains, *Petrie!* Campbell Island: *Hooker, T. Kirk! R. M. Laing!* December–March.

3. **G. setacea** *Hook. f. Fl. Nov. Zel.* i (1853) 267.—Perennial, densely tufted and compacted, forming broad moss-like patches sometimes 1–3 ft. across. Stems very numerous, branched, erect, leafy throughout, 1–3 in. high. Leaves numerous, erect, densely imbricate, ¼–¾ in. long, linear-setaceous with acicular tips; sheaths broad, membranous, quite glabrous, entire, produced at the tip into a free ligule. Scape terminal, rigid, erect, longer than the leaves. Floral bracts 2 or 3, alternate, convolute, appressed, obtuse, each 1-flowered or the uppermost empty. Hyaline scales absent. Stamens 2. Ovary of 2 connate collateral carpels; style 1 to each carpel, filiform. Fruiting carpels 2, or 1 by abortion.—*Handb. N.Z. Fl.* (1864) 297; *Cheesem. Man. N.Z. Fl.* (1906) 758.

South Island, Stewart Island: Not uncommon in mountain bogs throughout. 2500–4500 ft. December–March.

4. **G. ciliata** *Hook. f. Fl. Antarct.* i (1844) 85.—Forming soft green cushions in subalpine bogs sometimes several feet in diam. and 1–2 in. thick or more. Stems very densely compacted, erect, branched, leafy throughout. Leaves numerous, erect, imbricating, with broad scarious sheathing bases, ¼–½ in. long, linear-subulate, channelled in front or terete, tip obtuse or acute, sheaths and sometimes the lower part of the lamina more or less clothed with soft white hairs. Scape terminal, usually exceeding the leaves. Floral bracts 2, alternate but close together, jointed at the base, the lower one with an obtuse often hooked point. Flowers 1 or more rarely 2 to each bract, each flower with a hyaline scale almost as long as the bract. Stamen 1, sometimes deficient in one of the flowers; filament very long. Carpel usually solitary, sometimes 2 connate in the lower flower; style 1 to each carpel, long, filiform.—*Handb. N.Z. Fl.* (1864) 295. Centrolepis monogyna *T. Kirk in Journ. Linn. Soc.* xix (1882) 286. C. viridis *T. Kirk in Trans. N.Z. Inst.* xxiii (1891) 441; *Cheesem. Man. N.Z. Fl.* (1906) 758.

Var. **ligulata** *T. Kirk l.c.* 442.—More slender than the type. Leaves ½–¾ in. long, spreading, filiform, with larger sheaths, which are marginate, the upper part of the margin forming a kind of ligule.

North Island: Base of Ruapehu, *Petrie! T. F. C., Cockayne;* Kaimanawa Mountains, *B. C. Aston;* Tararua Mountains, *Petrie.* South Island: Common in subalpine bogs throughout. Stewart Island, Auckland and Campbell Islands: Abundant in boggy places in open situations. Usually from 2000 to 5000 ft., but descends to sea-level in Stewart Island and in the Subantarctic islands. Var. *ligulata:* Stewart Island, near Fraser Peaks.

Family XVIII. **JUNCACEAE.**

Perennial, rarely annual herbs. Rootstock short, stout, scaly. Stems usually simple, slender, stiff, erect, cylindrical or compressed, sometimes septate within. Leaves usually all radical, often rigid and terete like the stems, sometimes flat and grassy, occasionally absent or reduced to sheaths. Flowers small, green or brown, regular, hermaphrodite or more rarely unisexual, in axillary or terminal cymes or clusters, rarely solitary. Perianth inferior, coriaceous or scarious, persistent; segments 6 in 2 series, imbricate. Stamens usually 6, inserted on the bases of the perianth-segments, the 3 interior sometimes wanting; filaments free, flattened or filiform; anthers 2-celled, introrse. Ovary superior, 1-celled or 3-celled; style short or long; stigmas 3, filiform; ovules few or many, anatropous. Fruit a 1- or 3-celled capsule, loculicidally 3-valved. Seeds few or many, erect; testa membranous, often lax at each end; albumen copious, fleshy; embryo minute.

If restricted to the true *Junceae*, this is a family of moderate size, comprising 7 or 8 genera and about 280 species. The two typical genera (*Juncus* and *Luzula*) are widely dispersed, especially in temperate and extratropical regions. The species have no important properties, and cannot be said to possess any economic value.

Glabrous. Flower solitary. Ovary 1-celled, ovules many. Style long	1. Rostkovia.
Glabrous. Flowers several or numerous. Ovary often 3-celled, ovules many. Style short	2. Juncus.
Hairy. Flowers several or numerous. Ovary 1-celled, ovules 3. Style short	3. Luzula.

see Pfl. fam. 15a : 219.

1. **ROSTKOVIA** Desv. 1808

Densely tufted perennial herbs. Rhizome short, horizontal, branched. Stems crowded on the rhizome, strict, erect, terete. Leaves 1 or more, together with several sheathing scales at the base of the stem. Flowers large, solitary, terminal; bracts at the base 1–3, the lowest one sometimes foliaceous. Perianth-segments 6, glumaceous, distinct, linear-subulate or linear-lanceolate, erect, rigid; margins often scarious. Stamens 6; filaments very short; anthers linear, erect, basifixed. Ovary sessile, 1-celled, with 3 parietal placentas; style stout, subulate, divided above into 3 linear stigmas; ovules numerous, anatropous. Seeds small; testa appendiculate or not; embryo very small, included in the base of the fleshy albumen.

A small genus of 4 species confined to New Zealand and antarctic South America.

Flowers $\frac{1}{4}$ in. long, exceeded by a foliaceous bract. Capsule longer than the perianth. Seeds not tailed	1. *R. magellanica.*
Flowers $\frac{3}{4}$ in. long; bract very short. Capsule not more than $\frac{1}{2}$ as long as the perianth. Seeds tailed	2. *R. gracilis.*

Rostkovia Perianth-segments equal, seeds obovoid.

Marsippospermum Perianth-segments unequal, seeds pointed at each end.

1. **R. magellanica** *Hook. f. Fl. Antarct.* i (1844) 81.—Perennial, densely tufted. Stems many, crowded, erect, terete, 4–9 in. high. Leaves several, equalling or exceeding the stems, sheathing at the base, erect, rigid, pungent, polished, channelled in front. Flower solitary, terminal, $\frac{1}{4}$ in. long; bracts 2, the lower foliaceous, twice as long as the flower or more, upper small, scarcely equalling the flower. Perianth-segments nearly equal, linear-oblong, acute. Stamens shorter than the segments; filaments linear; anthers longer than the filaments, connective unguiculate. Capsule large, equalling or exceeding the perianth, ovoid-globose, mucronate, hard and almost woody, dark-chestnut, smooth and shining. Seeds obovoid, inappendiculate.—*Handb. N.Z. Fl.* (1864) 291; *Buchen. Monog. Junc.* (1890) 70; *Pflanzenr.* Heft 25 (1906) 40. R. sphaerocarpa *Desv. in Journ. Bot.* i (1808) 234; *Cheesem. Man. N.Z. Fl.* (1906) 722. Juncus magellanicus *Lam. Encycl.* iii (1789) 266.

Auckland and Campbell Islands: Mossy and springy places on the hills, *Hooker, B. C. Aston!*

Also recorded from Fuegia, the Falkland Islands, and South Georgia, and said to have been gathered on the Andes of Quito at an elevation of 13000 ft. It is included in Armstrong's list of Canterbury plants (Trans. N.Z. Inst. xii (1880) 344), but, I believe, erroneously.

2. **R. gracilis** *Hook. f. Fl. Antarct.* i (1844) 83, t. 47.—Perennial, densely tufted. Rhizome stout, horizontal or inclined. Stems numerous, crowded, erect, terete, smooth, 6–12 in. high, base with several pale or dark fulvous sheaths. Leaves 1–3, from slightly longer to 2 or even 3 times as long as the stems, slender, terete, rigid, grooved in front. Flower large, solitary, terminal, $\frac{1}{2}$–$\frac{3}{4}$ in. long; bract solitary, very small, $\frac{1}{10}$ in. long, entire or 2-lobed. Perianth-segments linear-subulate, pale-chestnut, shining, the inner conspicuously shorter. Stamens 6, much shorter than the segments; filaments very short, broad and flat; anthers linear, 3 or 4 times as long as the filaments, connective unguiculate. Capsule about $\frac{1}{3}$ in. long, narrow ovoid-oblong, obtusely trigonous, acute, chestnut-brown, coriaceous, smooth and shining, 3-valved. Seeds numerous, small, pale, produced at both ends into a long pearly-white appendage.—*Handb. N.Z. Fl.* (1864) 292; *Cheesem. Man. N.Z. Fl.* (1906) 722; *Ill. N.Z. Fl.* ii (1914) t. 203. R. novae-zealandiae *Buch. in Trans. N.Z. Inst.* iv (1872) 227, t. 16. Marsippospermum gracile *Buchen. in Abh. Nat. Ver. Brem.* vi (1879) 374; *Monog. Junc.* (1890) 68.

South Island: Not uncommon in alpine localities, especially in the central and western portions of the Island, usually between 4500–7000 ft. Auckland and Campbell Islands: Not uncommon in rocky places, 500–1200 ft. December–February.

Easily distinguished from the preceding species by the larger flower, relatively smaller capsule, and tailed seeds. Mr. Buchanan's *R. novae-zealandiae* was published in the belief that the Auckland Islands plant always had the leaves solitary and 2 or 3 times longer than the stems, but in point of fact both New Zealand and Auckland Islands specimens are variable in the number and length of the leaves.

Seeds small; testa appendiculate or not; embryo very small, included in the base of the fleshy albumen.

A small genus of 4 species confined to New Zealand and antarctic South America.

Flowers $\frac{1}{4}$ in. long, exceeded by a foliaceous bract. Capsule longer than the perianth. Seeds not tailed .. .. .. 1. *R. magellanica.*
Flowers $\frac{3}{4}$ in. long; bract very short. Capsule not more than $\frac{1}{2}$ as long as the perianth. Seeds tailed .. .. .. 2. *R. gracilis.*

Buchenau confines the genus *Rostkovia* to *R. magellanica*, reviving Desvaux's name of *Marsippospermum* for the three remaining species. But Hooker and Bentham, in the "Genera Plantarum," point out that at present *Rostkovia* constitutes a natural and well-defined genus, easily distinguishable by habit alone, and that the differences relied upon by Buchenau to separate his two groups are in reality much less pronounced than those which divide well-known species of *Juncus*, as, for instance, *J. bufonius* and *J. acutus*.

1. **R. magellanica** *Hook. f. Fl. Antarct.* i (1844) 81.—Perennial, densely tufted. Stems many, crowded, erect, terete, 4–9 in. high. Leaves several, equalling or exceeding the stems, sheathing at the base, erect, rigid, pungent, polished, channelled in front. Flower solitary, terminal, $\frac{1}{4}$ in. long; bracts 2, the lower foliaceous, twice as long as the flower or more, upper small, scarcely equalling the flower. Perianth-segments nearly equal, linear-oblong, acute. Stamens shorter than the segments; filaments linear; anthers longer than the filaments, connective unguiculate. AUCKLAND AND CAMPBELL ISLANDS: Mossy and springy places on the hills, *Hooker, B. C. Aston!*

Also recorded from Fuegia, the Falkland Islands, and South Georgia, and said to have been gathered on the Andes of Quito at an elevation of 13000 ft. It is included in Armstrong's list of Canterbury plants (Trans. N.Z. Inst. xii (1880) 344), but, I believe, erroneously.

2. **R. gracilis** *Hook. f. Fl. Antarct.* i (1844) 83, t. 47.—Perennial, densely tufted. Rhizome stout, horizontal or inclined. Stems numerous, crowded, erect, terete, smooth, 6–12 in. high, base with several pale or dark fulvous sheaths. Leaves 1–3, from slightly longer to 2 or even 3 times as long as the stems, slender, terete, rigid, grooved in front. Flower large, solitary, terminal, $\frac{1}{2}$–$\frac{3}{4}$ in. long; bract solitary, very small, $\frac{1}{10}$ in. long, entire or 2-lobed. Perianth-segments linear-subulate, pale-chestnut, shining, the inner conspicuously shorter. Stamens 6, much shorter than the segments; filaments very short, broad and flat; anthers linear, 3 or 4 times as long as the filaments, connective unguiculate. Capsule about $\frac{1}{3}$ in. long, narrow ovoid-oblong, obtusely trigonous, acute, chestnut-brown, coriaceous, smooth and shining, 3-valved. Seeds numerous, small, pale, produced at both ends into a long pearly-white appendage.—*Handb. N.Z. Fl.* (1864) 292; *Cheesem. Man. N.Z. Fl.* (1906) 722; *Ill. N.Z. Fl.* ii (1914) t. 203. R. novae-zealandiae *Buch. in Trans. N.Z. Inst.* iv (1872) 227, t. 16. Marsippospermum gracile *Buchen. in Abh. Nat. Ver. Brem.* vi (1879) 374; *Monog. Junc.* (1890) 68.

SOUTH ISLAND: Not uncommon in alpine localities, especially in the central and western portions of the Island, usually between 4500–7000 ft. AUCKLAND AND CAMPBELL ISLANDS: Not uncommon in rocky places, 500–1200 ft. December–February.

Easily distinguished from the preceding species by the larger flower, relatively smaller capsule, and tailed seeds. Mr. Buchanan's *R. novae-zealandiae* was published in the belief that the Auckland Islands plant always had the leaves solitary and 2 or 3 times longer than the stems, but in point of fact both New Zealand and Auckland Islands specimens are variable in the number and length of the leaves.

Pflan. fam. 15a : 214

2. **JUNCUS** Linn. 1735

Perennial or more rarely annual herbs; stems usually densely tufted. Leaves mostly or all radical, stout or slender, terete, compressed or flat, sometimes reduced to sheathing scales. Flowers small, hermaphrodite, in axillary or terminal fascicles or cymes or panicles. Perianth-segments 6, glumaceous, distinct, lanceolate or oblong, margins often scarious, the 3 outer often with the midrib keeled or thickened. Stamens 6 or rarely 3. Ovary more or less perfectly 3-celled, rarely 1-celled; ovules usually numerous in each cell; style divided to the middle into 3 linear stigmatic lobes. Capsule completely or incompletely 3-celled, 3-valved. Seeds small, ovoid or obovoid; testa minutely striate and reticulate.

A large genus of about 200 species, many of them widely distributed and some almost cosmopolitan. Of the 17 species found in New Zealand, 4 have a wide range, especially in the Northern Hemisphere; 9 extend to Australia and Tasmania, but not to any other countries; one stretches through Australia to eastern Asia and as far northwards as China and Japan; another occurs in antarctic South America; and 2 are endemic.

A. Genuini. *Stems tall, terete, produced beyond the cyme into an erect often pungent tip, base clothed with leafless sheaths. Leaves wanting, or rarely 1 or 2 terete like the stem.*

* Leaves wanting.

† Capsule conspicuously longer than the perianth, ovoid-trigonous.

Stems very tall and stout, 2–5 ft. × $\frac{1}{8}$–$\frac{1}{4}$ in. Flowers distinct in the cyme, not collected into separate groups. Stamens usually 6 — 1. *J. pallidus.*

Stems very slender, 9–24 in. × $\frac{1}{25}$–$\frac{1}{10}$ in. Cyme lax, flowers not very numerous, distinct in the cyme. Stamens 6–3 .. .. — 2. *J. pauciflorus.*

†† Capsule equalling the perianth or very slightly exceeding it.

Stems rather stout, 2–4 ft. × $\frac{1}{10}$–$\frac{1}{6}$ in. Flowers $\frac{1}{10}$–$\frac{1}{8}$ in., collected into many-flowered globose heads. Stamens usually 3. Capsule broadly oblong .. .. — 3. *J. vaginatus.*

Stems slender, 1–3 ft. × $\frac{1}{20}$–$\frac{1}{8}$ in. Flowers $\frac{1}{12}$–$\frac{1}{10}$ in., usually distinct in the cyme. Stamens 3. Capsule small, thin, almost globose .. .. — 4. *J. polyanthemos.*

** Leaves 1 or 2, terete like the stem.

Tall salt-marsh plant, 1–3 ft. Cyme large, many-flowered. Stamens 6. Capsule ovoid-trigonous .. .. .. — 5. *J. maritimus.*

B. Graminifolii. *Stem leafy at the base and sometimes upwards as well. Leaves flat or semiterete, not septate within.*

Annual, much branched. Leaves setaceous. Flowers pale, distinct .. .. — 6. *J. bufonius.*

Perennial, simple, 5–10 in. high. Leaves grassy, channelled. Flowers in clusters of 2–6 near the end of the stems .. .. — 7. *J. plebeius.*

Perennial, simple. Leaves grassy, flat or involute. Cyme terminal, lax. Flowers pale, distinct .. .. — 8. *J. tenuis.*

Tall, 6–18 in. Leaves flat, all radical. Flowers brown, in distinct clusters. Stamens 3.. .. .. — 9. *J. planifolius.*

Tall, 6–18 in. Leaves flat or involute, all radical. Flowers brown, in distinct clusters, contracted (in the N.Z. form) into a compound head. Stamens 6 .. .. — 10. *J. caespiticius.*

Small, 1–4 in. Leaves all radical, almost terete. Flowers brown, in a terminal 2–8-flowered head .. .. — 11. *J. antarcticus.*

C. Articulati. *Stem leafy at the base and often upwards as well. Leaves terete or compressed, septate within, the septa usually prominent externally.*

Stems 9–24 in., compressed, 2-edged. Leaves $\frac{1}{10}$–$\frac{1}{6}$ in. across, flat, multitubular. Cyme very large and compound; flowers brown. Stamens 3 .. .. — 12. *J. prismatocarpus.*

Stems 6–18 in. Leaves linear, overtopping the stems, terete or slightly compressed, unitubular. Cymes small, contracted; flowers greenish. Stamens 6 .. .. 13. *J. holoschoenus.*

Stems very slender, 6–18 in. Leaves linear-subulate, shorter than the stems, terete or compressed, unitubular. Cymes divaricate; flowers brown. Stamens 6 .. .. 14. *J. lampocarpus.*

Stems much branched, 2–8 in. Leaves narrow, compressed. Flowers pale, in 3–8-flowered fascicles. Capsule pale, equalling or slightly longer than the perianth .. .. .. 15. *J. scheuchzerioides.*

Stems much branched, 1–6 in. Leaves filiform, terete. Flowers brown, in 2–5-flowered fascicles. Capsule dark-brown or black, much exceeding the perianth .. .. 16. *J. novae-zealandiae.*

Stems much-branched, 1–6 in. Leaves filiform, terete. Flowers pale, in 2–3-flowered fascicles. Capsule pale, slightly exceeding the perianth .. .. 17. *J. pusillus.*

1. **J. pallidus** *R. Br. Prodr.* (1810) 258.—Pale greyish-green, densely tufted, very tall and robust, 2–5 ft. high. Rhizome short, very stout and woody. Stems often $\frac{1}{4}$ in. diam., cylindric, finely striate, with several large and lax sheathing scales at the base, which are usually dark-chestnut below, straw-coloured above, sometimes pale throughout; pith continuous, not irregularly interrupted. Inflorescence lateral; cymes large, much branched, effuse or contracted; branches unequal in length. Flowers $\frac{1}{8}$ in. long, pale, distinct or crowded on the ultimate branches of the cyme, in some forms almost secund. Perianth-segments lanceolate or ovate-lanceolate, acute, rather rigid, pale, the 3 inner slightly smaller than the outer. Stamens 6. Capsule exceeding the perianth, ovoid-trigonous, obtuse, pale, shining, incompletely 3-celled. Seeds very minute, ferruginous, obliquely oblong, tipped with a white point.—*Benth. Fl. Austral.* vii (1878) 130; *Buchen. Monog. Junc.* (1890) 237; *Pflanzenr.* Heft 25 (1906) 139; *Cheesem. Man. N.Z. Fl.* (1906) 725. J. vaginatus *Hook. f. Fl. Nov. Zel.* i (1853) 263; *Handb. N.Z. Fl.* (1864) 289 (*not of R. Br.*). J. macrostigma *Col. in Trans. N.Z. Inst.* xvii (1885) 253.

Var. **triandrus.** — Similar to the typical form in size and habit, but the pith interrupted with irregular cavities, stamens 3 only, and capsule smaller and blunter, more oblong in shape.

North and South Islands: Damp places from the Auckland Isthmus southwards, not uncommon. Sea-level to 2000 ft. December–February. Var. *triandrus:* Vicinity of Auckland, *T. F. C.;* Paterson's Inlet, Stewart Island, *Petrie!*

A common Australian plant. It is without doubt the *Juncus tenax* var. *major* of the Banks and Solander MSS., as pointed out by Dr. Rendle (Journ. Bot. xxxviii (1900) 80); but Brown's name is the earliest accompanied by a sufficient description. The typical state is easily recognized by its large size, the six stamens, and the ovoid-trigonous capsule considerably exceeding the perianth.

2. **J. pauciflorus** *R. Br. Prodr.* (1810) 259. — Usually very slender, 9–24 in. high. Rhizome short, horizontal, creeping. Stems densely crowded on the rhizome, $\frac{1}{25}$–$\frac{1}{10}$ in. diam., erect, terete, wiry, smooth or finely striate; pith continuous or interrupted; basal scales closely appressed, usually red-brown, smooth and shining below, strongly grooved above. Inflorescence lateral; cymes lax, irregularly compound; branches few, slender, spreading. Flowers not nearly so numerous as in the allied species and sometimes very few, distinct, about $\frac{1}{10}$ in. long, pale or dark-chestnut. Perianth-segments equal or the outer rather longer, lanceolate or ovate-lanceolate, acute or the inner obtuse, margins broad, membranous.

Stamens 6 or 3. Capsule exceeding the perianth, ovoid-trigonous, obtuse or shortly pointed, shining, stramineous to chestnut-brown, incompletely 3-celled. Seeds minute, obliquely obovoid, ferruginous, apiculate.—*Benth. Fl. Austral.* vii (1878) 129; *T. Kirk in Trans. N.Z. Inst.* xiv (1882) 384; *Buchen. Monog. Junc.* (1890) 238; *Pflanzenr.* Heft 25 (1906) 140; *Cheesem. Man. N.Z. Fl.* (1906) 725.

Var. **Gunnii** *Buchen. Monog. Junc.* (1890) 239.—Basal leaf-scales and flowers more deeply coloured. Stamens usually 6. Capsule longer, darker at the tip.—*Pflanzenr.* Heft 25 (1906) 141. J. Gunnii *Hook. f. Fl. Tasm.* ii (1860) 67.

North and South Islands: Both the species and variety not uncommon in wet places throughout. Sea-level to 2500 ft. December–February.

Also in Australia, where it ranges from Queensland to Tasmania. In its usual state distinguished without much difficulty by the small size, very slender stems, lax few-flowered inflorescence, and ovoid-trigonous capsule distinctly longer than the perianth, but specimens with a closer many-flowered inflorescence cannot be separated from *J. polyanthemos* in the absence of ripe fruit.

3. **J. vaginatus** *R. Br. Prodr.* (1810) 258.—Very densely tufted, rather stout, 2–3 ft. high or even more. Rhizome stout, woody, creeping. Stems very closely packed on the rhizome, $\frac{1}{12}$–$\frac{1}{6}$ in. diam., strict, erect, terete, finely striate; pith interrupted with irregular cavities; basal sheaths large, rather lax, smooth and shining and dark red-brown at the base, pale straw-coloured and distinctly grooved above. Inflorescence lateral, large, branched; the branches few or many, stiff, erect, rather close together, bearing distinct compact globose many-flowered heads. Flowers $\frac{1}{10}$–$\frac{1}{8}$ in. long, pale-brown. Perianth-segments lanceolate, acute, stramineous, the inner ones rather shorter than the outer. Stamens usually 3, rarely 6. Capsule equalling the perianth or only very slightly exceeding it, broadly oblong, obscurely trigonous, obtuse at the tip.—*Benth. Fl. Austral.* vii (1878) 129; *Buchen. in Engl. Bot. Jahr.* xxi (1895) 264; *Pflanzenr.* Heft 25 (1906) 141; *Cheesem. Man. N.Z. Fl.* (1906) 726. J. australis *Hook. f. Fl. Tasm.* ii (1860) 66, t. 13A; *Handb. N.Z. Fl.* (1864) 289. J. tenax *Sol. in Forst. f. Prodr.* (1786) n. 514, *fide Rendle in Journ. Bot.* xxxviii (1900) 80.

North and South Islands: Marshy places from the North Cape to Banks Peninsula, not uncommon. December–February.

This can be easily separated from the following species by the larger size, by the inflorescence being split up into distinct little rounded cymes or groups of flowers, and by the larger and rather narrower capsule; but some states are difficult to place. Smaller and more slender forms show an approach to *J. pauciflorus*, but the capsule of that species usually much exceeds the perianth.

4. **J. polyanthemos** *Buchen. in Engl. Bot. Jahr.* xx (1895) 261. Brownish-green, very densely tufted, 1–3 ft. high. Rhizome short, horizontal. Stems crowded on the rhizome, $\frac{1}{20}$–$\frac{1}{8}$ in. diam., soft or stiff and wiry, terete, finely striate; pith usually interrupted; basal sheaths appressed, rigid, opaque, smooth below, grooved above. Inflorescence lateral; cymes large, usually dense, but not contracted, much branched; branches slender, unequal. Flowers numerous, small, $\frac{1}{12}$–$\frac{1}{10}$ in. long, green or pale-chestnut, usually scattered along the branches of the cyme, rarely collected into groups. Perianth-segments thin, green, linear-lanceolate, equal or the outer rather longer, acute, thin, margins membranous. Stamens 3, shorter than the perianth; anthers linear. Fruit globose-trigonous, obtuse or almost retuse at the tip, thin, shining, pale ferruginous

or stramineous. Seeds numerous, obliquely obovoid, shortly apiculate; pale ferruginous.—*Pflanzenr.* Heft 25 (1906) 141. J. effusus *Hook. f. Fl. Nov. Zel.* i (1853) 263 (*in part*); *Buchen. Monog. Junc.* (1890) 228; *Cheesem. Man. N.Z. Fl.* (1906) 726 (*not of Linn.*). J. communis *E. Mey. Junc.* (1819) 20; *Benth. Fl. Austral.* vii (1878) 128; *Hook. f. Handb. N.Z. Fl.* (1864) 290. J. luxurians *Col. in Trans. N.Z. Inst.* xix (1887) 269.

Var. **Cheesemanii** *Buchen. l.c.* (1895) 262. — Flowers approximate in few distant spherical glomerules.—*Pflanzenr.* Heft 25 (1906) 142. J. pauciflorus var. Cheesemanii *Buchen. Monog. Junc.* (1890) 23.

North and South Islands, Stewart Island: Abundant in damp places throughout. Sea-level to 3000 ft. *Wiwi.* November–February.

The most abundant species of the genus in New Zealand, everywhere to be seen by the margins of swamps, or in undrained soils that are wet in winter. Whether it is identical with Buchenau's plant is not quite certain; but the common New Zealand form, easily distinguished by the slender rigid and wiry stems with interrupted pith, and with the capsule rounded and imperfectly 3-celled, agrees so closely with his description that I am unable to separate them. But apparently Buchenau has doubts on the subject, for in his recent monograph of the family (Das Pflanzenreich, Heft 25, p. 142) he remarks that *J. polyanthemos* is abundant in most of the Australian colonies, and especially so in Queensland, while in New Zealand only var. *Cheesemanii* is known. His position on this point is puzzling, seeing that he was provided with abundant specimens, and does not allude to them, either in his description of *J. polyanthemos* or under any of the allied species.

5. **J. maritimus** *Lam. Encycl.* iii (1789) 264; var. **australiensis** *Buchen. Monog. Junc.* (1890) 257. — Densely tufted, tall, stout, dark-coloured, 1–4 ft. high. Rhizome short, thick, horizontal. Stems crowded on the rhizome, rigid, wiry, terete, pungent, furnished at the base with several chestnut-brown sheathing scales, the upper 1 or 2 of which are produced into terete leaves similar to the stems but shorter than them. Inflorescence lateral; cymes large, lax, irregularly branched; branches strict, erect. Flowers about $\frac{1}{8}$ in. long, dark chestnut-brown, usually aggregated into little clusters. Perianth-segments lanceolate, acute, the inner rather shorter. Stamens 6; anthers linear. Capsule ovoid-trigonous, acute, only slightly exceeding the perianth, dark chestnut-brown. Seeds obovoid, very shortly tailed.—*Pflanzenr.* Heft 25 (1906) 155; *Cheesem. Man. N.Z. Fl.* (1906) 727. J. maritimus *A. Rich. Fl. Nouv. Zel.* (1832) 145; *A. Cunn. Precur.* (1836) n. 292; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 263; *Handb. N.Z. Fl.* (1864) 289.

North and South Islands: Brackish-water marshes or sands from the North Cape to Banks Peninsula and Okarito, abundant. Inland on the shores of Lake Rotorua, and by the Waikato River near Orakeikorako. December–January.

Also common on most parts of the Australian coast. It differs from the typical state of the species, which has a wide distribution in the North Temperate Zone, in the darker colour of the whole plant, in the smaller and more densely aggregated darker flowers, in the shorter capsule, and in the less evident tails to the seeds.

6. **J. bufonius** *Linn. Sp. Plant.* (1753) 328.—Annual, pale-green, much branched from the base, often forming dense tufts, 3–12 in. high; roots fibrous. Leaves radical and cauline, very narrow-linear or almost filiform, sheathing at the base, flat or channelled above, grassy, setaceous, pith not

Juncus bufonius, Linn.

not native to N.Z. see T.N.Z.I.

vol. 57, p. 65. (Ckn. & Allan).

Stamens 6 or 3. Capsule exceeding the perianth, ovoid-trigonous, obtuse or shortly pointed, shining, stramineous to chestnut-brown, incompletely 3-celled. Seeds minute, obliquely obovoid, ferruginous, apiculate.—*Benth. Fl. Austral.* vii (1878) 129; *T. Kirk in Trans. N.Z. Inst.* xiv (1882) 384; *Buchen. Monog. Junc.* (1890) 238; *Pflanzenr.* Heft 25 (1906) 140; *Cheesem. Man. N.Z. Fl.* (1906) 725.

Var. **Gunnii** *Buchen. Monog. Junc.* (1890) 239.—Basal leaf-scales and flowers more deeply coloured. Stamens usually 6. Capsule longer, darker at the tip.—*Pflanzenr.* Heft 25 (1906) 141. J. Gunnii *Hook. f. Fl. Tasm.* ii (1860) 67.

North and South Islands: Both the species and variety not uncommon in wet places throughout. Sea-level to 2500 ft. December–February.

Also in Australia, where it ranges from Queensland to Tasmania. In its usual state distinguished without much difficulty by the small size, very slender stems, lax few-flowered inflorescence, and ovoid-trigonous capsule distinctly longer than the perianth, but specimens with a closer many-flowered inflorescence cannot be separated from *J. polyanthemos* in the absence of ripe fruit.

3. **J. vaginatus** *R. Br. Prodr.* (1810) 258.—Very densely tufted, rather stout, 2–3 ft. high or even more. Rhizome stout, woody, creeping. Stems very closely packed on the rhizome, $\frac{1}{12}$–$\frac{1}{6}$ in. diam., strict, erect, terete, finely striate; pith interrupted with irregular cavities; basal sheaths large, rather lax, smooth and shining and dark red-brown at the base, pale straw-coloured and distinctly grooved above. Inflorescence lateral, large, branched; the branches few or many, stiff, erect, rather close together, bearing distinct compact globose many-flowered heads. Flowers $\frac{1}{10}$–$\frac{1}{8}$ in. long, pale-brown. Perianth-segments lanceolate, acute, stramineous, the inner ones rather shorter than the outer. Stamens usually 3, rarely 6. Capsule equalling the perianth or only very slightly exceeding it, broadly oblong, obscurely trigonous, obtuse at the tip.—*Benth. Fl. Austral.* vii (1878) 129; *Buchen. in Engl. Bot. Jahr.* xxi (1895) 264; *Pflanzenr.* Heft 25 (1906) 141; *Cheesem. Man. N.Z. Fl.* (1906) 726. J. australis *Hook. f. Fl. Tasm.* ii (1860) 66, t. 13A; *Handb. N.Z. Fl.* (1864) 289. J. tenax *Sol. in Forst. f. Prodr.* (1786) n. 514, *fide Rendle in Journ. Bot.* xxxviii (1900) 80.

North and South Islands: Marshy places from the North Cape to Banks Peninsula, not uncommon. December–February.

This can be easily separated from the following species by the larger size, by the inflorescence being split up into distinct little rounded cymes or groups of flowers, and by the larger and rather narrower capsule; but some states are difficult to place. Smaller and more slender forms show an approach to *J. pauciflorus*, but the capsule of that species usually much exceeds the perianth.

4. **J. polyanthemos** *Buchen. in Engl. Bot. Jahr.* xx (1895) 261. Brownish-green, very densely tufted, 1–3 ft. high. Rhizome short, horizontal. Stems crowded on the rhizome, $\frac{1}{20}$–$\frac{1}{8}$ in. diam., soft or stiff and wiry, terete, finely striate; pith usually interrupted; basal sheaths appressed, rigid, opaque, smooth below, grooved above. Inflorescence lateral; cymes large, usually dense, but not contracted, much branched; branches slender, unequal. Flowers numerous, small, $\frac{1}{12}$–$\frac{1}{10}$ in. long, green or pale-chestnut, usually scattered along the branches of the cyme, rarely

or stramineous. Seeds numerous, obliquely obovoid, shortly apiculate; pale ferruginous.—*Pflanzenr.* Heft 25 (1906) 141. J. effusus *Hook. f. Fl. Nov. Zel.* i (1853) 263 (*in part*); *Buchen. Monog. Junc.* (1890) 228; *Cheesem. Man. N.Z. Fl.* (1906) 726 (*not of Linn.*). J. communis *E. Mey. Junc.* (1819) 20; *Benth. Fl. Austral.* vii (1878) 128; *Hook. f. Handb. N.Z. Fl.* (1864) 290. Var. **Cheesemanii** *Buchen. l.c.* (1895) 262.—Flowers approximate in few distant spherical glomerules.—*Pflanzenr.* Heft 25 (1906) 142. J. pauciflorus var. Cheesemanii *Buchen. Monog. Junc.* (1890) 23.

North and South Islands, Stewart Island: Abundant in damp places throughout. Sea-level to 3000 ft. *Wiwi.* November–February.

The most abundant species of the genus in New Zealand, everywhere to be seen by the margins of swamps, or in undrained soils that are wet in winter. Whether it is identical with Buchenau's plant is not quite certain; but the common New Zealand form, easily distinguished by the slender rigid and wiry stems with interrupted pith, and with the capsule rounded and imperfectly 3-celled, agrees so closely with his description that I am unable to separate them. But apparently Buchenau has doubts on the subject, for in his recent monograph of the family (Das Pflanzenreich, Heft 25, p. 142) he remarks that *J. polyanthemos* is abundant in most of the Australian colonies, and especially so in Queensland, while in New Zealand only var. *Cheesemanii* is known. His position on this point is puzzling, seeing that he was provided with abundant specimens, and does not allude to them, either in his description of *J. polyanthemos* or under any of the allied species.

5. **J. maritimus** *Lam. Encycl.* iii (1789) 264; var. **australiensis** *Buchen. Monog. Junc.* (1890) 257.—Densely tufted, tall, stout, dark-coloured, 1–4 ft. high. Rhizome short, thick, horizontal. Stems crowded on the rhizome, rigid, wiry, terete, pungent, furnished at the base with several chestnut-brown sheathing scales, the upper 1 or 2 of which are produced into terete leaves similar to the stems but shorter than them. Inflorescence lateral; cymes large, lax, irregularly branched; branches strict, erect. Flowers about $\frac{1}{8}$ in. long, dark chestnut-brown, usually aggregated into little clusters. Perianth-segments lanceolate, acute, the inner rather shorter. Stamens 6; anthers linear. Capsule ovoid-trigonous, acute, only slightly exceeding the perianth, dark chestnut-brown. Seeds obovoid, very shortly tailed.—*Pflanzenr.* Heft 25 (1906) 155; *Cheesem. Man. N.Z. Fl.* (1906) 727. J. maritimus *A. Rich. Fl. Nouv. Zel.* (1832) 145; *A. Cunn. Precur.* (1836) n. 292; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 263; *Handb. N.Z. Fl.* (1864) 289.

North and South Islands: Brackish-water marshes or sands from the North Cape to Banks Peninsula and Okarito, abundant. Inland on the shores of Lake Rotorua, and by the Waikato River near Orakeikorako. December–January.

Also common on most parts of the Australian coast. It differs from the typical state of the species, which has a wide distribution in the North Temperate Zone, in the darker colour of the whole plant, in the smaller and more densely aggregated darker flowers, in the shorter capsule, and in the less evident tails to the seeds.

6. **J. bufonius** *Linn. Sp. Plant.* (1753) 328.—Annual, pale-green, much branched from the base, often forming dense tufts, 3–12 in. high; roots fibrous. Leaves radical and cauline, very narrow-linear or almost filiform, sheathing at the base, flat or channelled above, grassy, setaceous, pith not jointed. Cyme large, occupying the greater part of the stem; branches long or short, sometimes flexuous. Flowers $\frac{1}{6}$–$\frac{1}{4}$ in. long, sessile or nearly so, solitary or in fascicles of 2–3; bracteoles broadly ovate, scarious, much

shorter than the flowers. Perianth-segments lanceolate, acuminate, with broad scarious margins; the 3 inner rather shorter than the outer. Stamens usually 6, but sometimes 3 only in the terminal flowers. Capsule shorter than the erect perianth-segments, oblong, obtuse. Seeds numerous, minute, ovoid-oblong, obtuse, delicately lineolate.—*Hook. f. Fl. Nov. Zel.* i (1853) 264; *Handb. N.Z. Fl.* (1864) 290; *Benth. Fl. Austral.* vii (1878) 127; *Buchen. Monog. Junc.* (1890) 174; *Pflanzenr.* Heft 25 (1906) 105; *Cheesem. Man. N.Z. Fl.* (1906) 728.

North and South Islands, Chatham Islands, Stewart Island, Auckland Islands: From the Three Kings Islands and the North Cape southwards, abundant. Sea-level to 4000 ft. November–January.

Almost universally distributed in temperate climates. Doubtless introduced with grass-seed in the early days of colonization; but it now extends through the whole of the Dominion.

7. **J. plebeius** *R. Br. Prodr.* (1810) 259. — Densely tufted. Stems 5–10 in. high, smooth, strict, erect, compressed, leafy at the base. Leaves shorter than the stem, narrow, semi-terete, deeply channelled; sheaths close, convolute, produced into two obtuse auricles at the top. Inflorescence terminal. Flowers in clusters of 2–6 near the end of the stem, the flowers sessile in the clusters and usually spreading. Perianth-segments about $\frac{1}{4}$ in. long, lanceolate, rigid, coriaceous, long acuminate, the inner ones somewhat shorter. Stamens usually 3; filaments linear-filiform. Capsule rather shorter than the perianth, ovoid-trigonous. — *Buchen. Pflanzenr.* Heft 25 (1906) 115, t. 62. J. homalocaulis *F. Muell. in First Gen. Rep. Victoria* (1853) 19; *Benth. Fl. Austral.* vii (1878) 128; *Buchen. Monog. Junc.* (1890) 192.

North Island: Mongonui County, near Kaitaia and at Ahipara, *H. Carse!* Buchenau, in the Pflanzenreich, also records it from New Zealand, but without special locality, on the authority of "*Monrad in herb. Hann.*" It has probably been overlooked by other collectors.

8. **J. tenuis** *Willd. Sp. Plant.* ii (1799) 214. — A laxly tufted perennial, with a short rhizome and numerous wiry roots. Stems several in a tuft, slender, erect, wiry, terete, 9–18 in. high. Leaves few, mostly radical, usually shorter than the stem, very narrow-linear, grassy, flat or more generally involute or channelled; base sheathing, membranous. Cymes terminal, lax, much exceeded by the leafy filiform bracts. Flowers $\frac{1}{8}$–$\frac{1}{6}$ in. long, pale-green, remote or clustered. Perianth-segments lanceolate, acuminate, slightly spreading in fruit. Stamens 6, about $\frac{1}{2}$ the length of the perianth-segments; anthers ovate. Style very short. Capsule ovoid-trigonous or almost globose, obtuse or slightly retuse, rather shorter than the perianth-segments, pale stramineous. Seeds obliquely obovoid, minutely apiculate.—*Cheesem. in Trans. N.Z. Inst.* xi (1879) 433; *Buchen. Monog. Junc.* (1890) 193; *Pflanzenr.* Heft 25 (1906) 115; *Cheesem. Man. N.Z. Fl.* (1906) 728. J. involucratus *T. Kirk in Trans. N.Z. Inst.* ix (1877) 550 (*not of Steud.*).

North and South Islands: In various localities from Mangonui to Dunedin, not uncommon. Sea-level to 3000 ft. November–January.

An abundant North American plant, extending into some parts of South America, found also in western Europe, &c. It is a very doubtful native of New Zealand, and has certainly increased its range considerably of late years.

J. macer S.F. Gray *Trans* 1935: 65: 3.

9. **J. planifolius** *R. Br. Prodr.* (1810) 259.—Tufted, perfectly glabrous, 6–18 in. high. Roots many, long, fibrous. Leaves all radical, much shorter than the stems, numerous, flat and grassy, membranous, $\frac{1}{10}$–$\frac{1}{4}$ in. broad, dilated at the base into long imbricating sheaths. Flowering stems or culms long, slender, naked, bearing at the top an irregularly umbellately branched compound cyme; bracts at the base of the inflorescence usually 1 or 2, short, leafy, sometimes small and scarious. Flowers small, $\frac{1}{10}$ in. long, chestnut-brown, crowded in many-flowered heads at the ends of the branches of the cymes. Perianth-segments subequal or the outer rather shorter, oblong-lanceolate, acute. Stamens 3. Capsule equalling the perianth or very slightly longer than it, obovoid, trigonous, mucronate. Seeds numerous, minute, ovoid, very minutely reticulated.—*Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 263; *Handb. N.Z. Fl.* (1864) 290; *Benth. Fl. Austral.* vii (1878) 125; *Buchen. Monog. Junc.* (1890) 433; *Pflanzenr.* Heft 25 (1906) 249; *Cheesem. Man. N.Z. Fl.* (1906) 728.

Var. **chathamensis** *Buchen. Monog. Junc.* (1890) 434.—Slender, about 12 in. high. Leaves narrow, $\frac{1}{10}$ in. diam. Perianth-segments deeply coloured, a brown stripe down the centre, margins chestnut-black.—*Pflanzenr.* Heft 25 (1906) 250.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Abundant in moist places throughout. Sea-level to 3000 ft. November–January. Var. *chathamensis:* Chatham Islands, *H. H. Travers.*

An abundant plant throughout the greater part of Australia and Tasmania, also found in Chile.

10. **J. caespiticius** *E. Mey. in Lehm. Pl. Preiss.* ii (1846) 47; var. **bracteatus** *Buchen. Monog. Junc.* (1890) 439.—A tufted perennial 6–18 in. high; roots numerous, fibrous. Leaves all radical, much shorter than the stem, very numerous, grassy, erect, gradually tapering from a long and broad sheathing base to a long subulate acuminate point, margins involute. Flowering stems long, slender, naked. Cyme contracted into a dense conglobate head $\frac{1}{2}$–$1\frac{1}{2}$ in. diam.; bracts at the base 1–3, leafy, much exceeding the cyme. Flowers rather longer than in *J. planifolius*, about $\frac{1}{8}$ in. long, crowded in many-flowered fascicles. Perianth-segments unequal, the 3 outer distinctly shorter. Stamens 6, about $\frac{1}{2}$ the length of the segments. Capsule equalling the perianth or slightly exceeding it, ovoid-trigonous, obtuse, mucronate. Seeds minute, but rather larger than in *J. planifolius*, ovoid, smooth or very indistinctly reticulated.—*Benth. Fl. Austral.* vii

Leaves all radical, much shorter than the stem, very numerous, grassy, erect, gradually tapering from a long and broad sheathing base to a long subulate acuminate point, margins involute. Flowering stems long, slender, naked. Cyme contracted into a dense conglobate head $\frac{1}{2}$–$1\frac{1}{2}$ in. diam.; bracts at the base 1–3, leafy, much exceeding the cyme. Flowers rather longer than in *J. planifolius*, about $\frac{1}{8}$ in. long, crowded in many-flowered fascicles. Perianth-segments unequal, the 3 outer distinctly shorter. Stamens 6, about $\frac{1}{2}$ the length of the segments. Capsule equalling the perianth or slightly exceeding it, ovoid-trigonous, obtuse, mucronate. Seeds minute, but rather larger than in *J. planifolius*, ovoid, smooth or very indistinctly reticulated.—*Benth. Fl. Austral.* vii (1878) 126; *Buchen. Monog. Junc.* (1890) 439; *Pflanzenr.* Heft 25 (1906) 252; *Cheesem. Man. N.Z. Fl.* (1906) 729.

North and South Islands: From the Bay of Islands to Otago, rather local. November–January.

Closely allied to *J. planifolius*, with which it has been confounded by most New Zealand botanists. It can be distinguished by the narrower involute leaves, densely congested cymes, rather larger flowers, the stamens always 6 in number, and in the fewer and larger smoother seeds. The typical state, which is common in Australia, has the cyme laxly branched, with shorter bracts.

11. **J. antarcticus** *Hook. f. Fl. Antarct.* i (1844) 79, t. 46.—A small densely tufted perennial 1–4 in. high; roots long, fibrous. Leaves very numerous, all radical, equalling or shorter than the stems, suberect or curved, linear-subulate, flat towards the base, semiterete or obscurely canaliculate above, cylindric towards the apex, obtuse, pith not jointed within; sheathing base long, broad, margins scarious. Stem terete,

smooth, naked, terminating in a 2–8-flowered head, rarely a second head is produced lower down. Bracts ovate, membranous, rarely longer than the flowers. Flowers crowded, about $\frac{1}{8}$ in. long, dark chestnut-brown. Perianth-segments equal, lanceolate, acute. Stamens 3, rarely 6; anthers ovate. Capsule equalling the perianth, ovoid-trigonous, subacute. Seeds ovoid, obtuse, shining, obsoletely reticulate.—*Handb. N.Z. Fl.* (1864) 290; *Buchen. Monog. Junc.* (1890) 432; *Pflanzenr.* Heft 25 (1906) 249; *Cheesem. Man. N.Z. Fl.* (1906) 729. J. pauciflorus *T. Kirk in Trans. N.Z. Inst.* ix (1877) 551 (*not of R. Br.*). J. brevifolius *T. Kirk in Trans. N.Z. Inst.* xiv (1882) 382.

North Island: Rangipo Plain, near the foot of Ruapehu, *Petrie!* Waimarino, *T. F. C.* South Island: Nelson—Mount Arthur, Mount Owen, *T. F. C.*; Lake Rotoiti, *T. Kirk.* Canterbury—Broken River, *J. D. Enys! T. Kirk! T. F. C.*; Tasman Valley, *T. F. C.* Otago—Not uncommon in the central and southern districts, *Buchanan! Petrie!* Stewart Island: *T. Kirk!* Auckland and Campbell Islands: *Hooker, T. Kirk! B. C. Aston!* Usually from 1500–4000 ft., but descends to sea-level in Otago and the islands to the south. December–February.

A very distinct species. The Campbell Island plant is said to have 6 stamens and the culms hardly longer than the leaves, whereas in New Zealand the stamens are nearly always 3, and the culms usually (but not invariably) exceed the leaves. I agree with Professor Buchenau in considering Kirk's *J. brevifolius* to be a mere state of *J. antarcticus*.

12. **J. prismatocarpus** *R. Br. Prodr.* (1810) 259.—Perennial, laxly tufted. Stems erect or sometimes decumbent and rooting at the nodes towards the base, leafy, compressed, often 2-edged, not jointed, 9–24 in. high. Leaves always shorter than the stems, 3–9 in. long, $\frac{1}{12}$–$\frac{1}{8}$ in. broad, gradually narrowed to an acute tip, strongly compressed, flat, soft, multitubular, incompletely and often indistinctly septate; sheathing base long, compressed, tip with 2 obtuse lobes. Cyme very large and compound, with 1 or 2 short leafy bracts at the base; branches long, slender, divaricating. Flowers $\frac{1}{8}$–$\frac{1}{6}$ in. long, greenish or greenish-brown, in many-flowered globular clusters. Perianth-segments about equal, linear-lanceolate or subulate-lanceolate, acuminate. Stamens 3, much shorter than the segments. Capsule usually considerably longer than the perianth, pale, narrow, prismatic, triquetrous, 1-celled; placentas very feebly developed. Seeds ovoid, apiculate.—*Benth. Fl. Austral.* vii (1878) 131; *Buchen. Monog. Junc.* (1890) 311; *Pflanzenr.* Heft 25 (1906) 180; *Cheesem. Man. N.Z. Fl.* (1906) 730.

North Island: Wet places in lowland stations from the Bay of Islands to Wellington, not uncommon. South Island: Nelson—Motueka Valley, *T. F. C.* November–January.

Easily distinguished from *J. holoschoenus* by the strongly compressed stems, flattened and incompletely septate leaves, large spreading cymes, and by the stamens being 3 only. It is widely diffused in Australia and eastern Asia.

13. **J. holoschoenus** *R. Br. Prodr.* (1810) 259.—Stems laxly tufted, creeping at the base, strict and erect above, terete or subcompressed, smooth, leafy, 6–18 in. high. Leaves few, equalling or exceeding the stems, erect from a long sheathing base, tapering into a long acuminate point, terete or slightly compressed, fistular, completely and distinctly septate. Cymes terminal, sparingly branched, more or less contracted, usually of 3–8 fascicles, rarely more; bract at the base long, foliaceous, usually overtopping the cyme. Flowers 10–20 in each fascicle, greenish,

14. J. articulatus L. (See Brig. Prod. Fl. Corse 1, 264 : 1910)

about $\frac{1}{6}$ in. long. Perianth-segments equal, lanceolate, acuminate. Stamens 6, about $\frac{1}{2}$ the length of the perianth-segments. Capsule equalling the perianth or rather longer than it, narrow, prismatic, triquetrous, 1-celled, the placentas not very conspicuous inside the cells. Seeds ovoid-oblong, grooved and transversely rugose, apiculate at each end.—*Hook. f. Handb. N.Z. Fl.* (1864) 290; *Buchen. Monog. Junc.* (1890) 357; *Pflanzenr.* Heft 25 (1906) 207; *Cheesem. Man. N.Z. Fl.* (1906) 730. J. prismatocarpus *Benth. Fl. Austral.* vii (1878) 131 (*in part*). J. cephalotes *Hook. f. Fl. Nov. Zel.* i (1853) 263 (*not of Thunb.*). New Z. Journ. Bot. 6, 1968 Rec. C. Fl. 4 - 1935 ???

North Island: Swamps from the Bay of Islands southwards to Wellington, not common. Sea-level to 2500 ft. November–February.

Also found in Australia and Tasmania. Bentham unites it with *J. prismatocarpus*, from which it appears to me to be abundantly distinct, as pointed out under that species.

14. **J. lampocarpus** *Ehr. Calam.* (1791) n. 126.—Perennial, more or less densely tufted. Stems erect or ascending, rarely decumbent at the base, slender, terete or compressed, soft, leafy, 6–18 in. high. Leaves shorter than the stems, 3–9 in. long, $\frac{1}{20}$–$\frac{1}{12}$ in. broad, linear-subulate, nearly terete, unitubular, strongly septate;

Juncus lampocarpus, Ehr.

Perhaps not native to N.Z. see T.N.Z.I. vol. 57, p. 65. (Ckn. & Allan).

(1906) 731.

North and South Islands, Stewart Island: From Mangonui southwards, not uncommon in wet places. Sea-level to 3500 ft. November–February.

A common plant in many parts of the North Temperate Zone, but in the Southern Hemisphere apparently restricted to New Zealand. Perhaps not truly indigenous, although now widely spread, even in remote mountain districts.

15. **J. scheuchzerioides** *Gaud. in Ann.* Ser. *Nat.* Ser. i, 5 (1825) 100.—Stems usually much branched below, often prostrate and rooting, 2–8 in. long or more, leafy throughout. Leaves strict, erect, 1–5 in. long, far exceeding the culms, narrow-linear, attenuated at the apex, compressed, striate, pale-green, soft and herbaceous, pith with transverse joints; sheathing base long and broad, membranous, with 2 rounded auricles at the tip. Scape very short, much overtopped by the leaves, bearing 1 or 2 pale-coloured 3–8-flowered heads. Flowers crowded, $\frac{1}{8}$ in. long. Perianth-segments equal, lanceolate, acuminate, with scarious margins. Stamens 6, almost as long as the perianth-segments. Capsule equalling the perianth or rather longer than it, ovoid-trigonous. Seeds numerous, ovoid, obtuse, finely reticulated.—*Hook. f. Fl. Antarct.* i (1844) 80; *Handb. N.Z. Fl.* (1864) 291; *Cheesem. Man. N.Z. Fl.* (1906) 731; *Buchen. Monog. Junc.* (1890) 286; *Pflanzenr.* Heft 25 (1906) 171, t. 86.

South Island: Otago—Lake district, alpine, *Hector* and *Buchanan* (Handbook). Auckland and Campbell Islands: In boggy places, *Hooker, Cockayne, B. C. Aston!* Antipodes Island: *T. Kirk!* Macquarie Island, *H. Hamilton!*

smooth, naked, terminating in a 2–8-flowered head, rarely a second head is produced lower down. Bracts ovate, membranous, rarely longer than the flowers. Flowers crowded, about $\frac{1}{8}$ in. long, dark chestnut-brown. Perianth-segments equal, lanceolate, acute. Stamens 3, rarely 6; anthers ovate. Capsule equalling the perianth, ovoid-trigonous, subacute. Seeds ovoid, obtuse, shining, obsoletely reticulate.—*Handb. N.Z. Fl.* (1864) 290; *Buchen. Monog. Perianth-segments equal, lanceolate, acuminate, with scarious margins. Stamens 6, almost as long as the perianth-segments. Capsule equalling the perianth or rather longer than it, ovoid-trigonous. Seeds numerous, ovoid, obtuse, finely reticulated.—*Hook. f. Fl. Antarct.* i (1844) 80; *Handb. N.Z. Fl.* (1864) 291; *Cheesem. Man. N.Z. Fl.* (1906) 731; *Buchen. Monog. Junc.* (1890) 286; *Pflanzenr.* Heft 25 (1906) 171, t. 86.

South Island: Otago—Lake district, alpine, *Hector* and *Buchanan* (Handbook). Auckland and Campbell Islands: In boggy places, *Hooker, Cockayne, B. C. Aston!* Antipodes Island: *T. Kirk!* Macquarie Island, *H. Hamilton!*

I have seen no specimens of this from the mainland of New Zealand, but those gathered by H. Hamilton on Macquarie Island exactly correspond with others collected by Aston on Auckland Islands and by Kirk on Antipodes Island. But they all differ from Buchenau's fine plate in the Pflanzenreich in being much smaller, less branched, and having much less conspicuous leaf-sheaths. Buchenau appears to doubt the identity of the New Zealand plant with the South American, but does not state how they differ. *J. scheuchzerioides* is very closely allied to *J. pusillus* and *J. novae-zealandiae*, and small specimens, especially when in young flower, may easily be confused with either of them.

In the "Flora Antarctica" Hooker describes a var. *inconspicuus*, which is distinguished by its small size and minute leaves, which far exceed the solitary flowers. Hooker quotes Campbell Island as a habitat, but in the Pflanzenreich Buchenau limits it to the South American forms, and maintains it as a separate species.

16. **J. novae-zealandiae** *Hook. f. Fl. Nov. Zel.* i (1853) 264. — Stems very slender, much branched, densely tufted, often forming large patches, creeping and rooting at the base, erect above, 1–6 in. high. Leaves longer or shorter than the stem and sheathing it for the greater part of its length, very slender, filiform, terete, striate, pith with transverse joints; sheathing base long, membranous, with 2 rounded lobes at the tip. Flowers $\frac{1}{10}$ in. long, chestnut-brown, in 2–5-flowered fascicles; fascicles either solitary and terminal or 2–3 superposed. Perianth-segments ovate or ovate-lanceolate, obtuse, usually chestnut-brown, margins broad, membranous, hyaline. Stamens 6, equalling the perianth-segments or slightly exceeding them. Capsule $\frac{1}{8}$–$\frac{1}{6}$ in. long, much longer than the perianth, broadly ovoid-trigonous, obtuse, shortly mucronate, dark chestnut-brown or almost black, smooth, shining. Seeds minute, ovoid, pale-brown; testa minutely reticulate.—*Handb. N.Z. Fl.* (1864) 391; *Buchen. Monog. Junc.* (1890) 289; *Cheesem. Man. N.Z. Fl.* (1906) 732; *Buchen. Pflanzenr.* Heft 25 (1906) 172.

North and South Islands, Stewart Island: Mountain-swamps from the East Cape and Taranaki southwards, abundant. Sea-level to 4500 ft. December–March.

17. **J. pusillus** *Buchen. in Abh. Nat. Ver. Bremen*, vi (1879) 395. — Very similar to *J. novae-zealandiae* in habit and general appearance, but paler, rather smaller, and still more slender. Leaves longer or shorter than the stems, capillary, terete, striate, pith with transverse joints; sheaths thin and membranous, with hyaline margins and 2 rounded lobes at the top. Flowers pale-coloured, small, about $\frac{1}{12}$ in. long, solitary or in 2–3-flowered fascicles; fascicles seldom more than one. Perianth-segments lanceolate or ovate-lanceolate, acute or subacute, pale-green; margins membranous. Stamens 6, equalling the perianth-segments or rather longer. Capsule $\frac{1}{10}$ in. long, slightly exceeding the perianth, narrow ovoid-trigonous, shortly beaked, pale, smooth. Seeds smaller and narrower than in *J. novae-zealandiae.*—*Monog. Junc.* (1890) 290; *Cheesem. Man. N.Z. Fl.* (1906) 732; *Buchen. Pflanzenr.* Heft 25 (1906) 172. J. capillaceus *Hook. f. Fl. Nov. Zel.* i (1853) 264; *Handb. N.Z. Fl.* (1864) 291; *Fl. Tasm.* ii (1860) 65, t. 134B; *Benth. Fl. Austral.* vii (1878) 132 (*not of Lamarck*).

North and South Islands: Swampy places from the Bay of Plenty southwards, not so common as *J. novae-zealandiae.* Sea-level to 4000 ft. December–March.

There is little to distinguish this from the preceding species, except the smaller size, the smaller paler-coloured flowers, and the narrower capsule, which is frequently scarcely longer than the perianth. I have several states that appear to be quite intermediate. It is also found in south-eastern Australia and Tasmania.

L. Traversii and L. ulophylla have acute leaf-tips.

3. **LUZULA** DC.

Perennial herbs, usually tufted. Leaves grass-like, mostly radical, more or less ciliate with long flexuous white hairs. Flowers small, crowded in small fascicles or placed singly, the fascicles or single flowers arranged in an irregularly branched simple or compound umbel or cyme, sometimes contracted into a globose or spiciform head, each flower with a bract and 2 bracteoles. Perianth-segments 6, glumaceous, distinct. Stamens 6, hypogynous or the 3 inner attached to the base of the segments; filaments filiform; anthers oblong or linear. Ovary sessile, 1-celled; style filiform with 3 long stigmatic lobes; ovules 3, erect from a short basal placenta. Capsule 3-valved. Seeds 3, or fewer by abortion, globose or ovoid; testa minutely reticulated.

Species about 65, most plentiful in the temperate portions of the Northern Hemisphere, also found on the mountains of the tropics. The Australian and New Zealand species are all very near to the protean *L. campestris*, and are so highly variable as to present an almost inextricable series of closely allied forms.

* Small, 1–2 in. high, forming compact cushion-shaped masses.

Stems much shorter than the leaves and concealed by them. Flowers pale .. .. 1. *L. Colensoi.*
Stems about equalling the leaves. Inflorescence simple. Perianth-segments lanceolate, acute .. .. 2. *L. micrantha.*
Stems exceeding the leaves. Inflorescence usually simple. Perianth-segments subulate, acuminate, dark-chestnut with very narrow margins .. .. 3. *L. pumila.*
Stems exceeding the leaves. Inflorescence usually compound. Perianth-segments ovate-lanceolate, acuminate, with broad white margins .. .. 4. *L. Cheesemanii.*

** Stems often densely tufted but never forming cushion-shaped masses.

Small, slender, 1–4 in. high. Inflorescence a terminal solitary 3–8-flowered head. Stamens 3 .. .. 5. *L. leptophylla.*
Variable in size, 4–18 in. Leaf-tip obtuse, often callous. Inflorescence lax or contracted, many-flowered .. .. .. 6. *L. campestris.*
Usually from 6 to 14 in. Leaf-tip subulate, acute. Inflorescence of dense spikes congested into a pyramidal head .. .. 7. *L. Traversii.*
Stems 4–8 in. Leaves 1½–2½ in. Margins and back covered with entangled white woolly hairs; tip subulate, acute. Inflorescence of a single ovoid-globose head .. .. 8. *L. ulophylla.*

1. **L. Colensoi** *Hook. f. Handb. N.Z. Fl.* (1864) 293.—Small, moss-like, densely tufted, nearly glabrous, forming rounded cushions 1–3 in. across. Stems very short. Leaves much longer than the stems, $\frac{1}{4}$–$\frac{3}{4}$ in. long, subulate, tapering from a broad sheathing base to an obtuse tip, rigid and coriaceous, channelled in front, convex on the back, glabrous above the middle, margins of the sheath and lower part of the leaf sparingly ciliate. Inflorescence of 2 to 6 few-flowered fascicles compacted into a dense head concealed among the leaves; lower bracts leafy, exceeding the flowers; remainder small, white, membranous, lacerate. Flowers about $\frac{1}{12}$ in. long. Perianth-segments equal, ovate-lanceolate, acute or subacute, chestnut-brown with pale membranous margins and tips. Stamens 6, from slightly shorter to slightly longer than the segments. Capsule almost equalling the perianth, ovoid-globose, trigonous, red-brown. Seeds ferruginous, obliquely ovoid.—*Buchen. Monog. Junc.* (1890) 145; *Pflanzenr.* Heft 25 (1906) 96; *Cheesem. Man. N.Z. Fl.* (1906) 734; *Ill. N.Z. Fl.* ii (1914) t. 204A.

Aston!* Mount Holdsworth, *W Townson!* South Island: Nelson—Gordon's Nob, Mount Owen, Mount Peel, *T. F. C.* Westland—Kelly's Hill, *Petrie! Cockayne!* Otago—Longwood Range, *T. Kirk!* 4000–6500 ft. January–February.

Var. **macrostemon** *Buchen. in Oesterr. Bot. Zeit.* (1898) 210.—Stamens distinctly overtopping the perianth-segments; seeds not carunculate.

Easily distinguished by its small size and very short stems, the flowers being sunk among the leaves. Buchenau's var. *macrostemon*, separated on account of the stamens slightly exceeding the perianth, does not appear to me to be really distinct, the stamens often varying in length.

2. **L. micrantha** *Buchen. in Oesterr. Bot. Zeit.* (1898) 166, 243.—Densely tufted, forming compact rounded patches. Stems rigid, erect, $\frac{1}{2}$–$1\frac{1}{2}$ in. high, leafy at the base. Leaves equalling the stems, straight, rigid, erect, narrow-linear, obtuse at the tip, broadly sheathing at the base, flat or slightly concave in front, rounded or almost flat at the back; margins cartilaginous, glabrous; sheaths membranous, striate, slightly ciliate at the tip. Inflorescence simple, terminal, capitate, 3–8-flowered; the lowest bract (or the 2 lowest) foliaceous, overtopping the inflorescence, the remainder small, membranous, lacerate. Flowers about $\frac{1}{10}$ in. long. Perianth-segments equal, lanceolate, acute, reddish-brown, with very narrow hyaline margins. Stamens 6, rather more than $\frac{1}{2}$ as long as the perianth-segments. Capsule elliptic-trigonous, almost equalling the perianth, acute, shining, red-brown, paler at the base.—*Pflanzenr.* Heft 25 (1906) 96; *Cheesem. Man. N.Z. Fl.* (1906) 734.

Var. **triandra** *Cheesem. Man. N.Z. Fl.* (1906) 734.—Size and habit of the type, but leaves rather narrower, often curved, and usually canaliculate. Heads 6–12-flowered. Stamens 3.—L. triandra *Buchen. l.c.*

Var. **crenulata** *Cheesem. l.c.*—Very densely pulvinate. Leaves very narrow, subulate, canaliculate. Inflorescence 2–6-flowered. Perianth-segments crenulate at the tips. Stamens 6. Capsule obovoid, trigonous, obtuse.—L. crenulata *Buchen. l.c.*

South Island: Otago—Mount Cardrona, *Petrie!* Vars. *triandra* and *crenulata*: Rock and Pillar Range, *Petrie!* 4000–6000 ft. December–February.

The three plants united here under the name of *L. micrantha* are considered by Buchenau to represent three distinct species. I possess very poor material; but so far as it goes, I should hesitate at giving them higher rank than that of varieties.

3. **L. pumila** *Hook. f. Handb. N.Z. Fl.* (1864) 293.—Small, densely tufted, forming small cushion-shaped masses. Stems slender, erect, 1–2 in. high. Leaves shorter than the stems, $\frac{1}{3}$–1 in. long, linear-subulate, gradually narrowed to an obtuse tip, strict, erect, rigid, striate, channelled in front, convex behind, margins of the lower half and sheath sparingly ciliate. Inflorescence a dense terminal 4–10-flowered head; lowest bract foliaceous; the rest membranous, lacerate, pale chestnut-brown. Flowers about $\frac{1}{10}$ in. long, chestnut-brown. Perianth-segments subulate-lanceolate, long acuminate, the 3 outer distinctly larger, dark-chestnut, without pale margins or with very indistinct ones. Stamens 6, about $\frac{1}{2}$ as long as the perianth-segments. Capsule broadly obovoid, trigonous, from $\frac{1}{2}$ to $\frac{2}{3}$ the length of the perianth, dark chestnut-brown or almost black. Seeds oblong, minutely carunculate at the base.—*Buchen. Monog. Junc.* (1890) 144; *Pflanzenr.* Heft 25 (1906) 97; *Cheesem. Man. N.Z. Fl.* (1906) 735.

North Island: Mount Egmont, *Cockayne*. South Island: Nelson—Mountains above the Wairau Gorge, *T. F. C.*; Mount Captain, *T. Kirk!* Canterbury—Mount Torlesse, *Haast! T. F. C.*; Craigieburn Mountains, *Cockayne!* Mount Arrowsmith, *Cockayne* and *R. M. Laing!* Mount Darwin, *Haast!* Mount Dobson, *T. F. C.* Otago—Not uncommon on the central and western mountains, *Petrie!* 4000–6500 ft. January–February.

Best recognized by the stems distinctly overtopping the leaves, lanceolate-subulate perianth-segments, which are dark-chestnut with a very inconspicuous pale margin, and short almost black capsule.

4. **L. Cheesemanii** *Buchen. Monog. Junc.* (1890) 146.—Small, densely tufted, forming compact patches. Stems slender, erect, 1–2 in. high. Leaves shorter than the stems or equalling them, $\frac{1}{2}$–$1\frac{1}{2}$ in. long, linear-subulate, obtuse at the tip, rigid, concave in front, rounded on the back, grooved, margins ciliated throughout with long white hairs. Inflorescence of from 1 to 3 2–6-flowered fascicles congested into a terminal head; lowest bract leafy, often reddish, equalling the head; the remainder small, white, membranous. Flowers $\frac{1}{9}$ in. long. Perianth-segments about equal, ovate-lanceolate, acute, thin, with a blackish-chestnut stripe down the centre and very broad silvery-white margins. Stamens 6, about $\frac{1}{2}$ as long as the perianth-segments. Capsule shorter than the perianth, ovoid-globose, trigonous, mucronate, dark chestnut-brown or almost black. Seeds obliquely ovoid, minutely carunculate at the base.—*Pflanzenr.* Heft 25 (1906) 98; *Cheesem. Man. N.Z. Fl.* (1906) 735; *Ill. N.Z. Fl.* ii (1914) t. 204B.

South Island: Nelson—Summit of Gordon's Nob, *T. F. C.* Marlborough—Mount Mouatt, *T. Kirk!* Canterbury—Black Range, *T. F. C.*; Craigieburn Mountains, *Petrie!* Mount Peel, *H. H. Allan.* Otago—Mount Kyeburn, Dunstan Mountains, *Petrie!* 4000–6000 ft. December–February.

Closely allied to *L. pumila*, from which it differs in the more compound inflorescence, and in the much broader perianth-segments, with very conspicuous silvery-white margins.

5. **L. leptophylla** *Buchen. and Petrie in Oesterr. Bot. Zeit.* (1898) 214, 243, t. 7.—Small, slender, stoloniferous, 1–4 in. high. Leaves all radical, much shorter than the stems, $\frac{1}{2}$–2 in. long, very narrow, almost filiform, tip obtuse, margins convolute, glabrous or nearly so, mouth of the sheath with a tuft of slender hairs. Inflorescence terminal, of a single 3–8-flowered head, or more rarely the head consists of 2 closely compacted clusters; bract at the base of the head small, leafy. Flowers small, about $\frac{1}{12}$ in. long. Perianth-segments about equal or the outer a little shorter, ovate or ovate-lanceolate, acute, central portion dark chestnut-brown or almost black; margins broad, pale, membranous. Stamens 3, filaments filiform. Capsule equalling the perianth, rounded-obovoid, shining, dark-chestnut, sometimes almost black.—*Buchen. in Pflanzenr.* Heft 25 (1906) 81; *Cheesem. Man. N.Z. Fl.* (1906) 736.

South Island: Otago—Mount Kyeburn, *Petrie!* 2000–3500 ft. December–January.

A very curious little plant, of which I have seen no specimens except Mr. Petrie's. It appears to differ from reduced states of *L. campestris* in the exceedingly slender stems, almost filiform leaves, and 3 stamens.

6. **L. campestris** *DC. Fl. Fr.* iii (1805) 161.—Excessively variable in all its parts. Stems more or less densely tufted, stout or slender, very variable in size, usually from 6–14 in. high, but often reduced to 2 in., and sometimes reaching 18 or 20 in. Leaves mostly radical, always shorter

L. weltrainii Buch. Oest. Bot. Zeit. 1898: 72.

than the stems, generally flat and grassy, but varying in breadth from $\frac{1}{10}$ to $\frac{1}{3}$ in., gradually narrowed into an obtuse and usually callous tip; margins flat or thickened, more or less ciliate with long hairs and often copiously so. Inflorescence very variable, in the most developed forms of numerous clusters on the branches of an umbellate cyme, the branches very unequal in length; but frequently the clusters are greatly reduced in number, and the branches are often so short that the inflorescence is congested into a pyramidal or ovoid entire or lobed head. Lower bracts foliaceous; upper membranous, entire or lacerate, more or less ciliate. Flowers $\frac{1}{10}$–$\frac{1}{6}$ in. long. Perianth-segments ovate or ovate-lanceolate, acute, subequal, margins usually membranous, often white. Stamens 6. Capsule equalling the perianth, broadly ovoid or obovoid, trigonous, obtuse, usually shortly mucronate.—*Hook. f. Fl. Nov. Zel.* i (1853) 264; *Handb. N.Z. Fl.* (1864) 292; *Benth. Fl. Austral.* vii (1878) 292; *Buchen. Monog. Junc.* (1890) 155, *and in Oesterr. Bot. Zeit.* (1898) 161, t. 7; *also in Pflanzenr.* Heft 25 (1906) 83; *Cheesem. Man. N.Z. Fl.* (1906) 736.

(Kos. et A. Rich) Buchen. in Oestr. Bot. Zeit.

Var. **picta** *Hook. f. Handb. N.Z. Fl.* (1864) 292.—Slender, often flaccid, 3–18 in. high. Leaves flat, grassy. Inflorescence lax, the clusters rather few, the lateral ones peduncled. Flowers $\frac{1}{8}$–$\frac{1}{6}$ in. long. Perianth-segments linear-lanceolate, long-acuminate, with very broad white membranous margins and a narrow stripe of dark or pale chestnut-brown down the middle. Capsule shorter than the perianth, obovoid, trigonous.—L. picta *A. Rich. Fl. Nouv. Zel.* (1832) 146; *A. Cunn. Precur.* (1836) n. 295; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 265; *Buchen. Monog. Junc.* (1890) 146. L. subclavata *Col. in Trans. N.Z. Inst.* xviii (1886) 276. L. campestris DC. *var.* picta *Buchen. in Oesterr. Bot. Zeit.* (1898) 217, *and in Pflanzenr.* Heft 25 (1906) 88; *Cheesem. Man. N.Z. Fl.* (1906) 737.

North and South Islands, Stewart Island: Abundant throughout, usually in shaded places. Sea-level to 3500 ft.

(L. maxima)

Var. **Banksiana** *Buchen. in Oesterr. Bot. Zeit.* (1898) 218. — Stout. Stems strict, about 8–10 in. high. Leaves numerous, equalling the stem or sometimes exceeding them, broad, sometimes $\frac{1}{3}$ in. broad; margins thickened, long-ciliate. Inflorescence congested into a large conglobate head; bracts 2–3, not exceeding the inflorescence. Perianth-segments narrow-lanceolate, acute, a chestnut stripe down the centre, the remainder white. Capsule shorter than the perianth.—*Pflanzenr.* Heft 25 (1906) 90; *Cheesem. Man. N.Z. Fl.* (1906) 737. L. Banksiana *E. Mey. in Linnaea*, xxii (1849) 412. L. picta *var.* Banksiana *Buchen. Monog. Junc.* (1890) 147.

L. campestris var. picta (Hook. f. & A. Rich) Hook. f. Handb. 1864

North Island: *Banks* and *Solander, fide Buchenau.* Stewart Island: *Cockayne.* I have not seen specimens of this, which is probably an intermediate form between *picta* and *australasica.*

(Steud.) Stewart.

Var. **australasica** *Buchen. l.c.* 216.—Rather stout, 3–12 in. high or more. Leaves flat, coriaceous, $\frac{1}{8}$–$\frac{1}{3}$ in. broad; margins thickened, cartilaginous, conspicuously ciliate. Inflorescence contracted into an ovoid head $\frac{1}{4}$–$\frac{3}{4}$ in. diam., often with several smaller lateral pedunculated heads. Upper bracts ciliate. Flowers about $\frac{1}{8}$ in. long. Perianth-segments lanceolate, acuminate, margins broad, white, membranous, central stripe chestnut-brown or red. Capsule ovoid-trigonous, slightly shorter than the perianth.—*Buchen. in Pflanzenr.* Heft 25 (1906) 92; *Cheesem. Man. N.Z. Fl.* (1906) 737. L. australasica *Steud. Syn. Pl. Glum.* ii (1855) 294. L. Oldfieldii *Hook. f. Fl. Tasm.* ii (1860) 68; *Handb. N.Z. Fl.* (1864) 293; *Benth. Fl. Austral.* vii (1878) 122; *Buchen. Monog. Junc.* (1890) 154.

North and South Islands, Chatham Islands, Stewart Island: Hilly and mountainous districts from Taupo southwards, ascending to 4000 ft. Buchenau remarks, in his paper "*Luzula campestris* und Verwandte Arten," that this form can no longer be regarded as a distinct species. Its chief characteristics are the compact inflorescence, the thickened margins of the leaves, and the colour of the perianth-segments, which are brownish beneath, and more or less pure-white above, with a narrow chestnut stripe down the centre. It varies into the varieties *picta, migrata,* and *crinita.*

L. rhadina Balch. Kunow 3000 ft. D. Petrie

Var. **Petriana** *Buchen. l.c.* 219.—Rather stout, tufted, 4–12 in. high. Leaves narrow, $\frac{1}{15}$–$\frac{1}{8}$ in. broad, sparingly ciliate. Inflorescence compound, usually with the lateral clusters shortly stipitate, or rarely the inflorescence may be contracted into a conglobate head. Upper bracts more or less lacerate. Perianth-segments lanceolate, acute, dark chestnut-brown without white margins or very narrow ones. Capsule shorter than the perianth.—*Pflanzenr.* Heft 25 (1906) 92; *Cheesem. Man. N.Z. Fl.* (1906) 737.

North and South Islands, Stewart Island, Auckland Islands: Apparently abundant in hilly or mountain districts throughout, ascending to 4500 ft. I have seen no specimens from the Auckland Islands, but Buchenau refers to one collected by T. Kirk. To var. *Petriana* I refer his *L. Wettsteinii* (*Pflanzenr.* Heft 25 (1906) 81).

Var. **floribunda** *Buchen. in Pflanzenr.* Heft 25 (1906) 93.—Stout, densely tufted; stems firm, 10–15 in. high. Basilar leaves numerous, rather broad, apex channelled, obtuse at the tip. Lowest bracts 2–4, large, leafy, equalling or exceeding the inflorescence; bracts of the flower small, scarcely ciliate. Heads very numerous (Buchenau has counted as many as 55), 20- to 25-flowered, $\frac{1}{5}$–$\frac{1}{3}$ in. diam. Perianth-segments lanceolate, acute, chestnut, the inner segments paler at the tip. Caruncle of seed small.

South Island, Stewart Island, Auckland Islands: Apparently not uncommon in mountain districts throughout. Wairau Gorge, Mount Peel, Waimakariri Glacier, *T. F. C.*; Craigieburn Mountains, *Cockayne!* Otira River and Kelly's Hill, *Petrie!* Auckland Islands, *B. C. Aston! J. S. Tennant.* Dr. Buchenau considers that the affinity of this plant is with var. *crinita*.

Var. **crinita** *Buchen. in Oesterr. Bot. Zeit.* (1898) 215.—Stout, strict, 3–14 in. high. Leaves numerous, flat or involute, $\frac{1}{12}$–$\frac{1}{4}$ in. broad; margins thickened, densely and conspicuously ciliate. Inflorescence contracted into a compact ovoid head, sometimes with 1–3 smaller lateral peduncled ones. Lower bracts long, ciliate, involucrate; upper membranous, lacerate and densely ciliate. Flowers $\frac{1}{10}$ in. long. Perianth-segments lanceolate, long-acuminate, dark chestnut-brown, sometimes almost black. Capsule almost equalling the perianth.—*Buchen. in Pflanzenr.* Heft 25 (1906) 93; *Cheesem. Man. N.Z. Fl.* (1906) 737. L. crinita *Hook. f. Fl. Antarct.* i (1844) 84, t. 48; *Handb. N.Z. Fl.* (1864) 293; *Buchen. Monog. Junc.* (1890) 151.

Auckland and Campbell Islands, Macquarie Island: Abundant from sea-level to 1500 ft. The typical form appears to be confined to the above localities, but specimens with intermediate characters between it and *australasica*, *floribunda*, and *migrata* are not uncommon in the mountains of the South Island.

Var. **migrata** *Buchen. l.c.* 242.—Very closely allied to the northern *L. campestris* var. *multiflora*, differing chiefly in the shorter and more slender stems, often bulbous at the base, narrower leaves, and smaller inflorescence. Stems tufted, 4–15 in. high. Leaves $\frac{1}{8}$–$\frac{1}{5}$ in. broad; margins flat, not usually cartilaginous, ciliate, but not conspicuously so. Inflorescence well developed, usually lax, the lateral clusters pedunculate. Perianth-segments lanceolate, acute, dark chestnut-brown with white membranous margins.—*Pflanzenr.* Heft 25 (1906) 94; *Cheesem. Man. N.Z. Fl.* (1906) 737. L. campestris *var. a Hook. f. Handb. N.Z. Fl.* (1864) 292. L. rhadina *Buchen. l.c.* 212 (a form with very narrow erect leaves).

North and South Islands, Stewart Island, Chatham Islands: Abundant throughout, from sea-level to 4500 ft.

L. campestris is widely distributed in temperate and montane districts in most parts of the world, and particularly in New Zealand, where it has developed into a bewildering variety of closely allied forms. In arranging the New Zealand forms I have mainly followed Buchenau's memoir entitled "*Luzula campestris* und Verwandte Arten," published in Oesterr. Bot. Zeit., 1898. It is necessary for the student to bear in mind that the characters given for the varieties are those of prominent forms only, that intermediates between all of them are plentiful, and that aberrant states are not uncommon.

7. **L. Traversii** *Cheesem. n. comb.*—Stems densely tufted, very variable in size, usually from 6 to 12 in., but sometimes attaining 18 in. and occasionally dwarfed to 4 in., slender, often attenuate above. Leaves

radical and a few cauline, all much shorter than the stem, 1–6 in. long, rarely more, $\frac{1}{10}$–$\frac{1}{4}$ in. broad at the base and from thence gradually tapering upwards, apex subulate, not obtuse as in the forms of *L. campestris;* margins flat or involute, ciliate with long hairs. Inflorescence terminal, erect or nodding, compound, of several short and dense spikes either all congested into an ovoid head, or the lower 1 to 3 distinct and sometimes peduncled. Lower bracts foliaceous, often overtopping the inflorescence; upper membranous, with very broad white margins and apices, densely ciliate with long hairs. Flowers small, $\frac{1}{10}$ in. long. Perianth-segments equal, or the outer slightly longer, lanceolate, awned, pale-chestnut with white and silvery margins. Stamens 3, rarely more. Capsule equalling the perianth, ovoid-globose, trigonous, mucronate, pale- or dark-chestnut, sometimes almost black. Seeds oblong-ovoid, ferruginous.—L. racemosa *Desv. Journ. Bot.* i (1808) 162; *var.* Traversii *Buchen. Monog. Junc.* (1890) 133, *and in Pflanzenr.* Heft 25 (1906) 75; *Cheesem. Man. N.Z. Fl.* (1906) 738.

South Island: Nelson—Mountains above the Wairau Gorge, *T. F. C.* Marlborough—Mount Mouatt, *T. Kirk!* Canterbury—Broken River basin and Upper Waimakariri, *T. Kirk! T. F. C., Cockayne!* Mount Peel, *H. H. Allan!* Mount Arrowsmith district, *Cockayne* and *R. M. Laing;* Mount Cook district, *T. F. C.* Otago—Mount Pisa, Mount Kyeburn, Old Man Range, Mount Ida, *Petrie!* Mount Earnslaw, *Cockayne!* 2000–5500 ft. December–February.

Probably an abundant mountain-plant, but it is often confounded with varieties of *L. campestris* with congested inflorescence. From all these it can be readily distinguished by the tapering leaves ending in an acute subulate point quite unlike the obtuse and often swollen leaf-tip of *L. campestris;* also by the spiciform clusters, and by the broad bracts with white membranous margins densely ciliate with long hairs. I cannot agree with Dr. Buchenau in treating it as a variety of the South American *L. racemosa.* That species is a much larger plant, sometimes reaching a height of 2 ft. 6 in., whereas *L. Traversii* very rarely exceeds 14 in., and is usually much less. The breadth of the leaves is also greatly different. In *L. racemosa* they hardly ever exceed $\frac{1}{8}$ in., whereas in *L. Traversii* they frequently reach $\frac{1}{3}$ in. The inflorescence is also larger and more compound in *L. racemosa.*

(Buch.)

8. **L. ulophylla,** *Cockayne and Laing in Trans. N.Z. Inst.* xliii (1911) 366.—Densely tufted, forming small patches. Stems small, slender, strict, 4–8 in. high, rarely more. Leaves mostly at the base of the stem, than which they are much shorter, $1\frac{1}{2}$–$2\frac{1}{2}$ in. long, seldom more than $\frac{1}{2}$ in. broad, straight or curved, convolute, margins and back covered with a scurfy coating of entangled white woolly hairs; cauline leaves, when present, seldom more than one, minute, base sheathing the stem and appressed to it. Inflorescence terminal, of a single ovoid-oblong or almost spherical head $\frac{1}{4}$–$\frac{1}{2}$ in. long. Bracts pale. Capsule dark-chestnut.—L. racemosa *var.* ulophylla *Buchen. in Oesterr. Bot. Zeit.* (1898) 245, *and in Pflanzenr.* Heft 25 (1906) 75; *Cheesem. Man. N.Z. Fl.* (1906) 738.

South Island: Nelson—Clarence Valley, near Fowler's Pass, *T. F. C.* Canterbury—Castle Hill, *T. F. C., Cockayne!* Mount Arrowsmith district, *Cockayne* and *R. M. Laing.* Otago—Lake Wanaka, *Petrie!* 2000–5000 ft. December–February.

A very curious little plant, probably not uncommon in the higher mountain-valleys of the southern half of the South Island. In the first edition of this work I stated my opinion that it was worthy of being ranked as a distinct species, and further study has fully confirmed this view. I was therefore glad to note that Cockayne and Laing, in their report on the Botany of the Mount Arrowsmith District (Trans. N.Z. Inst. xliii (1911) 366) has published it as such.

L. campestris × racemosa
var. ulophylla Buch. 1898.

Family XIX. LILIACEAE.

Perennial herbs, rarely shrubs or trees. Root fibrous, or rhizome tuberous or bulbous or creeping. Stem herbaceous or woody, erect or climbing, tall or scarcely produced beyond the radical leaves. Leaves usually in radical tufts, or crowded at the ends of the stems or branches, or scattered along the branches, very various in size, shape, and texture. Flowers usually regular, hermaphrodite or rarely unisexual, inflorescence very various. Perianth inferior, petaloid; tube long or short; limb 6-lobed or -partite; segments in 2 series, imbricate or rarely valvate. Stamens 6, rarely 3, inserted towards the base of the perianth-segments and opposite to them, rarely hypogynous; filaments free or connate at the base; anthers oblong or linear, 2-celled, versatile. Ovary superior, 3-celled (sometimes imperfectly so in *Astelia*); style usually simple with a small terminal stigma, or more or less deeply divided into 3 stigmatic branches; ovules few or many in each cell, attached to the inner angle, usually anatropous. Fruit a 3-celled (rarely 1-celled) capsule or berry. Seeds 1 or more in each cell, globose or angular or flattened; testa frequently black, crustaceous or membranous; albumen copious, fleshy or horny; embryo small, terete.

A very large and important family, found all over the world, but more abundant in temperate and subtropical regions than in the tropics. It is frequently divided into 3 or 4 separate families, but in a small Flora it seems advisable to avoid extreme subdivision. Genera estimated at 200, species about 2800. The order has many useful species. The onion, leek, garlic, and asparagus are well-known edible plants. Aloes, squills, and sarsaparilla are important medicines. *Phormium* produces one of the strongest of vegetable fibres. Some are dangerous poisons, as white hellebore and meadow-saffron. Among the multitude of showy garden plants it will be sufficient to mention the lily, tulip, hyacinth, asphodel, lily of the valley. Of the 10 genera found in New Zealand, *Phormium* extends to Norfolk Island; *Rhipogonum*, *Herpolirion*, and *Arthropodium* occur in Australia, the latter in New Caledonia as well; *Enargea* in Chile and the Falkland Islands; *Astelia* in Australia, the Pacific islands, and temperate South America; *Bulbinella* in South Africa; the remaining three (*Cordyline*, *Dianella*, and *Iphigenia*) are widely distributed.

A. Fruit a berry.

* Leaves with distant parallel primary veins connected by transverse veinlets.

Tall branching climber. Leaves usually opposite. Flowers racemose or paniculate .. .. 1. RHIPOGONUM.

Stems short, wiry, creeping. Leaves alternate. Flowers solitary or 2–3, axillary .. .. 2. ENARGEA.

** Veins of leaves not connected by transverse veinlets.

Stems woody, usually arborescent. Leaves crowded at the ends of the stem or branches, glabrous. Flowers hermaphrodite; perianth deciduous .. .. 3. CORDYLINE.

Large tufted herbs. Leaves all radical, more or less clothed with silky hairs. Flowers dioecious; perianth persistent .. 4. ASTELIA.

Tufted herbs. Leaves all radical, glabrous. Flowers hermaphrodite; filaments thickened upwards.. .. .. 5. DIANELLA.

B. Fruit a capsule.

Leaves long, narrow, coriaceous. Scape tall, branched above. Perianth tubular, curved.. .. .. 6. PHORMIUM.

Leaves linear, fleshy. Scape stout, naked. Flowers racemose, yellow; filaments naked .. .. 7. BULBINELLA.

Scape stout, with leafy bracts. Flowers panicled, white; pedicels jointed in the middle. Filaments bearded .. .. 8. ARTHROPODIUM.

Small alpine herb. Rhizome creeping. Leaves distichous. Flowers large, solitary, sessile. Style filiform .. .. 9. HERPOLIRION.

Small herbs. Rootstock a tunicate corm. Leaves few. Flower small. Styles 3 .. .. 10. IPHIGENIA.

SMILACACEAE (Hutch. 109)

1. **RHIPOGONUM** Forst. 1776

Tall climbing shrubs, much branched above. Leaves opposite or nearly so, 3–5-nerved with transverse reticulated veins between; petioles without tendrils. Flowers hermaphrodite, small, shortly pedicelled, racemose; racemes axillary or terminal, simple or compound, sometimes forming a terminal panicle. Perianth deciduous; segments 6, all equal or the outer ones shorter. Stamens 6, hypogynous; filaments very short, flattened; anthers erect, longer or shorter than the perianth. Ovary superior, sessile, 3-celled; style short, stout; stigmas 3, thick, recurved; ovules solitary or geminate in each cell. Fruit a globose berry, usually 1-seeded by abortion, rarely 2–3-seeded. Seeds globose; testa thin, appressed; embryo small, remote from the hilum.

In addition to the single species found in New Zealand, there are four others in Australia.

1. **R. scandens** *Forst. Char. Gen.* (1776) 50.—A tall glabrous climber. Stems slender, knotted at the joints, often forming interwoven masses difficult to penetrate. Leaves opposite or very rarely alternate, petiolate, 3–5 in. long, narrow ovate-oblong to oblong-lanceolate, acute or acuminate, coriaceous, 3- or 5-nerved, the intermediate veinlets copiously reticulated. Racemes axillary, simple or branched, 3–6 in. long, the upper ones sometimes forming a terminal panicle. Flowers small, greenish, about $\frac{1}{3}$ in. diam.; pedicels slender, spreading. Perianth-segments very small, oblong-lanceolate, acute. Stamens 6, much longer than the perianth; filaments short, thick; anthers very large, linear-lanceolate. Ovary ovoid-globose; ovules geminate in each cell; style short, thick; stigma large, obsoletely 3-lobed. Berry globose, $\frac{1}{3}$ in. diam., bright-red.—*A. Rich. Fl. Nouv. Zel.* (1832) 151; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 253; *Handb. N.Z. Fl.* (1864) 281; *Benth. in Hook. Ic. Plant.* t. 1395; *Cheesem. Man. N.Z. Fl.* (1906) 703; *Ill. N.Z. Fl.* ii (1914) t. 200. R. parviflorum *R. Br. Prodr.* (1810) 293; *A. Cunn. Precur.* (1836) n. 305. Smilax Ripogonum *Forst. f. Prodr.* (1786) n. 372.

North and South Islands, Stewart Island, Chatham Islands: Lowland forests from the North Cape southwards, abundant. Sea-level to 2000 ft. *Supplejack; Kareao; Pirita.* November–December.

A familiar plant to all bushmen, especially in the northern part of the Dominion. In the South Island it is mainly found near the coasts. The long, tough, and elastic stems have been used for baskets, hurdles, &c.; and an extract from the root has been employed in the place of sarsaparilla.

PHILESIACEAE (Hutch. 117)

Luzuriaceae Nom. cons. Ruiz et Pav. Fl. Peruv. 3: 62. 1802.

2. **ENARGEA** Banks and Sol. ex Gaertn. 1788

Glabrous almost suffruticose herbs. Stems slender, branched, wiry, knotted at the joints, lower joints with small membranous scales. Leaves alternate, sessile or nearly so, distichous, lanceolate to oblong, prominently nerved. Flowers white, solitary or 2–4 in the axils of the leaves. Perianth deciduous; segments 6, distinct, subequal, spreading, thin, nerveless. Stamens 6, hypogynous; filaments erect; anthers linear-oblong, basifixed, longitudinally dehiscent. Ovary sessile, ovoid, 3-celled; ovules 4–10 in each cell; style filiform; stigma terminal, capitate or obsoletely 3-lobed. Berry subglobose, indehiscent. Seeds few, ovoid or subglobose; testa thin, appressed; embryo short, straight; albumen horny.

In addition to the New Zealand species are two others from Chile. I agree with the late Baron Mueller ("Victorian Naturalist," December, 1886) in considering that *Enargea* should take precedence over both *Callixene* and *Luzuriaga*. *Enargea* was published by Gaertner from Solander's notes in 1788, whereas *Callixene* did not appear until 1789, and *Luzuriaga* in 1802. *Enargea* appears to have been rejected on account of an error in Gaertner's plate, but that does not seem to be a sufficient reason for setting aside the name.

1. **E. parviflora** *Skottsberg in Plant World*, xviii (1915) 133.—Stems slender, branched, wiry, flexuous, creeping at the base, 4–12 in. long or more. Leaves alternate, sessile or very shortly petioled, $\frac{1}{2}$–$1\frac{1}{4}$ in. long, linear-oblong to oblong, mucronate, pale-green, rather rigid, coriaceous, margins perfectly smooth, longitudinally 5–7-nerved; transverse veinlets few; all veinlets conspicuous on both surfaces. Flowers solitary, terminal or in the upper axils, white, $\frac{1}{2}$–$\frac{3}{4}$ in. diam.; pedicels short, slender, erect. Perianth-segments subequal, ovate-lanceolate, acute. Stamens not $\frac{1}{2}$ the length of the segments; filaments glabrous. Berry globose, $\frac{1}{3}$ in. diam., white.—E. marginata *Cheesem. Man. N.Z. Fl.* (1906) 704 (*not of Banks and Sol.*). Callixene parviflora *Hook. f. Fl. Nov. Zel.* i (1853) 254; *Handb. N.Z. Fl.* (1864) 281. C. melalantha *Col. in Trans. N.Z. Inst.* xvii (1885) 250. Luzuriaga parviflora *Kunth Enum. Pl.* v (1850) 281. L. marginata *Cheesem. Ill. N.Z. Fl.* ii (1914) t. 201 (*not of Benth.*).

North and South Islands, Stewart Island: Mountain forests from Cape Colville and the Thames goldfields southwards, not uncommon. Sea-level to 3500 ft. *Puwatawata.* November–February.

In the first edition of this work I followed Bentham in uniting the New Zealand species with the Fuegian and Falkland Islands *E. marginata*. But Dr. Skottsberg, who has recently made a comparison between the two, finds that *E. marginata* has flowers twice as large, and the veins of the leaves are obsolete and their margins scabrous; whereas the New Zealand plant, in addition to the much smaller flowers, has the leaf-margins smooth, and their veins evident. He has consequently revived Hooker's name of *E. parviflora* for our plant.

AGAVACEAE

3. CORDYLINE Comm.

Trees or shrubs; trunk long or short, sometimes almost wanting. Leaves crowded at the top of the stem or its branches, more rarely alternate along the stem, sessile or petioled, very long, coriaceous; veins parallel, more or less oblique to the midrib. Flowers hermaphrodite, in terminal much-branched panicles, solitary or fascicled along the branches, shortly pedicellate or almost sessile. Perianth narrow-campanulate or cylindric, 6-partite; segments narrow, all equal or the 3 inner rather longer. Stamens 6, inserted at the base of the segments, shorter or longer than them; filaments filiform or flattened; anthers narrow-oblong, dorsifixed. Ovary 3-celled; style filiform; stigma capitate or shortly 3-lobed; ovules numerous (4–16) in each cell. Berry globose, 3-celled, at first more or less succulent, but often dry when the seeds are fully ripe. Seeds few or many in each cell, sometimes solitary by abortion, usually curved; testa black, shining.

About 12 or 15 species are known, scattered through India, Malaya, Polynesia, and New Zealand, together with one species in South America. With the exception of the wide-ranging *C. terminalis*, all the species found in New Zealand are endemic.

Cordyline kaspar n.sp. Three Kings Is. 1889
Records Auck. Inst.& Museum.Vol.4.no.6.Oct.56.

A. Leaves contracted into a long and narrow canaliculate petiole.

Leaves 1–2½ ft., broadly oblanceolate or narrow-oblong; lateral veins fine. Panicle 1–2 ft.; branches simple, spreading. Flowers lilac	1. *C. terminalis.*
Leaves 3–6 ft., linear-lanceolate; lateral veins strong, prominent. Panicle 2–5 ft., much branched. Flowers white	2. *C. Banksii.*

B. Leaves sessile, ensiform, not contracted into a conspicuous petiole.

Stem 15–40 ft. Leaves 1½–3 ft. × 1½–2½ in., rather thin; lateral veins fine, green	3. *C. australis.*
Stem 5–20 ft. Leaves 2–6 ft. × 4–6 in., excessively thick and coriaceous; lateral veins coarse, conspicuous, red or yellow ..	4. *C. indivisa.*
Stem wanting or very short. Leaves 1–3 ft. × ¼–⅔ in., narrow-linear	5. *C. pumilio.*

1. **C. terminalis** *Kunth in Abh. Acad. Berl.* (1820) 30.—Stem slender, 3–8 ft. high. Leaves numerous, crowded, 1–2½ ft. long, 2–5 in. broad, broadly oblanceolate or almost oblong, acute or acuminate, gradually narrowed into a long petiole, thinly coriaceous, pale-green, midrib distinct beneath but obscure above; lateral veins numerous, fine, distinct, oblique; petiole 2–6 in. long, deeply canaliculated above, obtusely keeled beneath, dilated and sheathing at the base. Panicle 1–2 ft. long, broad, laxly branched; branches spreading, the lower ones again divided. Flowers solitary or 2–3 together along the branches of the panicle, sessile or very shortly pedicelled, ⅓ in. long, lilac; bracteoles 3, small, deltoid. Perianth-segments equal, longer than the tube. Stamens not exceeding the segments. Berry globose, ⅓ in. diam.—*Benth. Fl. Austral.* vii (1878) 21; *Cheesem. in Trans. N.Z. Inst.* xx (1888) 174; *Man. N.Z. Fl.* (1906) 706. C. Cheesemanii *T. Kirk in Trans. N.Z. Inst.* xxviii (1896) 508.

Kermadec Islands: Lower portions of Sunday Island, not common, *T. F. C.* North Island: Formerly cultivated by the Maoris in the Bay of Islands and other northern districts, now nearly extinct. *Ti-pore.* July–September.

A most abundant plant throughout Polynesia, and stretching northwards through Queensland and New Guinea to Malaya and India. I have examined the specimens, cultivated in Mr. Reid's garden at Ahipara, upon which Mr. Kirk founded his *C. Cheesemanii.* They differ in no respect from the common Polynesian form of *C. terminalis,* and as they were found in an abandoned Maori cultivation they can only be looked upon as survivors from a period when the species was grown by the Maoris for food purposes. Archdeacon Walsh (Trans. N.Z. Inst. xxxiii (1901) 201) mentions other instances of *C. terminalis* having been found in old Maori cultivations, and argues with much probability that the plant was originally introduced by the Maoris on their first colonization of New Zealand.

2. **C. Banksii** *Hook. f. in Gard. Chron.* (1860) 792.—Stems slender, simple or sparingly branched, or several from the base forming large clumps, 4–10 ft. high. Leaves numerous, very long, erect below, drooping towards the tips, 3–6 ft. or even more, 1½–3½ in. broad at the middle, linear-lanceolate, acuminate, gradually contracted into a petiole 1–2 ft. long, striate and obliquely many-nerved, 4–8 of the nerves on each side of the midrib stronger than the rest and either green or red or yellowish; midrib stout, flat above, prominent and rounded beneath; petiole deeply channelled above, rounded beneath. Panicles one or several to each stem, suberect or drooping, very large and lax, much and diffusely branched, 2–5 ft. long. Flowers longer and narrower than in *C. australis,* and not so closely placed, nearly ½ in. long, white, sessile or nearly so; bracteoles very small. Berry globose, ½ in. diam., white. Seeds 2–3 in each cell.—*Handb. N.Z. Fl.* (1864) 282; *Cheesem. Man. N.Z. Fl.* (1906) 706.

North and South Islands: Abundant from the North Cape to Marlborough, Nelson, and Westland. Sea-level to 3500 ft. *Ti-ngahere.* November–December.

A very distinct species, easily recognized by the large many-nerved leaves gradually narrowed into long slender petioles, large lax panicles, and long narrow flowers.

(Forst. f.)

3. **C. australis** *Hook. f. in Gard. Chron.* (1860) 792.—Variable in size and habit. Stems of young trees straight, erect, unbranched; of mature ones much branched above or more rarely from the base, 15–40 ft. high; trunk 1–5 ft. diam.; bark thick, rough and fissured. Leaves of young plants scattered along the stem, 1–2 ft. long, ½–1 in. broad; of older plants forming a dense round head at the top of the stem or branches, 1½–3 ft. long, 1½–2½ in. broad, ensiform, acute or acuminate, contracted just above the broad sheathing base but not petiolate, flat, firm, coriaceous: midrib

North and South Islands: Abundant throughout. Stewart Island: Rare, *T. Kirk.* Sea-level to 2500 ft. *Ti; Ti-kauka; Ti-rahau; Palm-lily.* November–January.

Universally known to New Zealand residents by the inappropriate name of "cabbage-tree." The foliage yields a strong and durable fibre, and has been recommended for paper-making. Largely planted for scenic effect in gardens and shrubberies, and extensively grown for decorative purposes in Europe. Varieties with bronzy or variegated foliage are occasionally seen. Mr. Colenso's *C. Sturmii* has broader and thinner leaves, and may be entitled to recognition as a variety, but at present I am only acquainted with it through a single indifferent specimen.

4. **C. indivisa** *Steud. Nom.* ed. ii, i (1824) 419.—Stem stout, erect, rarely branched, 5–25 ft. high. Leaves very numerous, spreading all round and forming an enormous massive head, 2–6 ft. long, 4–6 in. broad at the middle, broadly ensiform, acuminate, usually contracted below and again expanded at the sheathing base, excessively thick and coriaceous, flat, greenish with a faint purplish or reddish tint above, glaucous beneath, midrib very thick and prominent at the base, but gradually decreasing in size upwards, lateral veins very numerous, strong, parallel, oblique to the midrib and with it usually coloured red or reddish-yellow. Panicle very large, densely branched, pendulous, 2–4 ft. long including the stout peduncle; bracts at the base

North and South Islands: Abundant throughout. Stewart Island: Rare, *T. Kirk.* Sea-level to 2500 ft. *Ti; Ti-kauka; Ti-rahau; Palm-lily.* November–January.

Universally known to New Zealand residents by the inappropriate name of "cabbage-tree." The foliage yields a strong and durable fibre, and has been recommended for paper-making. Largely planted for scenic effect in gardens and shrubberies, and extensively grown for decorative purposes in Europe. Varieties with bronzy or variegated foliage are occasionally seen. Mr. Colenso's *C. Sturmii* has broader and thinner leaves, and may be entitled to recognition as a variety, but at present I am only acquainted with it through a single indifferent specimen.

4. **C. indivisa** *Steud. Nom.* ed. ii, i (1824) 419.—Stem stout, erect, rarely branched, 5–25 ft. high. Leaves very numerous, spreading all round and forming an enormous massive head, 2–6 ft. long, 4–6 in. broad at the middle, broadly ensiform, acuminate, usually contracted below and again expanded at the sheathing base, excessively thick and coriaceous, flat, greenish with a faint purplish or reddish tint above, glaucous beneath, midrib very thick and prominent at the base, but gradually decreasing in size upwards, lateral veins very numerous, strong, parallel, oblique to the midrib and with it usually coloured red or reddish-yellow. Panicle very large, densely branched, pendulous, 2–4 ft. long including the stout peduncle; bracts at the base

broad, massive, the lower ones usually exceeding the panicle; branches very close-set, divided at the base, simple above, 1 in. across with the flowers on. Flowers shortly pedicelled, densely crowded, $\frac{1}{3}$ in. long, white; bracteoles of the lower flowers sometimes equalling them, of the upper ones minute. Perianth-tube campanulate; segments sharply recurved. Anthers broadly oblong. Berry $\frac{1}{4}$ in. diam., globose, bluish. Seeds 5–6 in each cell, angled; testa black, shining.—*Hook. f. Fl. Nov. Zel.* i (1853) 258; *Gard. Chron.* (1860) 792; *Handb. N.Z. Fl.* (1864) 282; *Cheesem. Man. N.Z. Fl.* (1906) 282; *Cockayne Veg. N.Z.* (1921) t. 36. C. Hookeri *T. Kirk in Trans. N.Z. Inst.* xxv (1893) 334. C. Hectori *Col. in Trans. N.Z. Inst.* xxv (1893) 334. Dracaena indivisa *Forst. f. Prodr.* (1786) n. 150; *Pl. Escul.* (1786) n. 33; *A. Rich. Fl. Nouv. Zel.* (1832) 148; *A. Cunn. Precur.* (1836) n. 301.

North Island: Mountain districts from the Thames goldfields and Te Aroha southwards. South Island: Along the western side from Collingwood and Westport to Dusky Sound. On the eastern side in several localities on Banks Peninsula, *J. B. Armstrong.* 1500–4000 ft. *Toii.* December–January.

By far the finest species of the genus. I have followed Sir J. D. Hooker in considering the plant common in subalpine localities in the North Island and north-west portion of the South Island to be the same as Forster's *Dracaena indivisa*, originally gathered in Dusky Sound. Most New Zealand botanists, however, treat the two forms as distinct, apparently on the ground of the supposed larger and longer flowers of the southern plant. But, so far as I am aware, flowering specimens of Forster's plant do not exist in any New Zealand herbarium, and the earlier descriptions are in conflict with one another as to the size of the flower. As there is little, if any, difference in habit or foliage, it appears to me that the most prudent course is to keep the two plants together until a thorough comparison of their characters can be made.

5. **C. pumilio** *Hook. f. in Gard. Chron.* (1860) 792. — Small, usually stemless, but in some varieties with a short slender stem 1–3 ft. high. Leaves very numerous, densely rosulate, 1–3 ft. long, $\frac{1}{4}$–$\frac{2}{3}$ in. broad, narrow-linear, acuminate, coriaceous; lateral veins several, evident, parallel; midrib stout, prominent on both surfaces; margins often finely scaberulous. Panicles terminal, erect or inclined, very slender, laxly branched, 1–3 ft. long; branches long, slender, spreading. Flowers irregularly scattered along the branches, rather remote, shortly pedicelled, small, white or bluish-white, $\frac{1}{5}$ in. diam.; pedicels variable in length. Perianth-segments oblong, obtuse. Berry globose, $\frac{1}{5}$ in. diam., bluish-white. Seeds 1 or 2 in each cell.—*Handb. N.Z. Fl.* (1864) 282; *Cheesem. Man. N.Z. Fl.* (1906) 708. C. stricta *Hook. f. Fl. Nov. Zel.* i (1853) 257, t. 58 (*not of Endl.*).

North Island: From the North Cape to Wellington, but rare and local to the south of the East Cape. Sea-level to 1500 ft. *Ti-rauriki.* November–December.

A variable plant, but well marked by the small size, usually stemless habit, narrow leaves, lax slender panicle, and small flowers. The roots are fleshy and saccharine, and were formerly cooked and eaten by the Maoris.

4. **ASTELIA** Banks and Sol.

Large or small densely tufted perennial herbs, usually more or less clothed with silky or chaffy hairs or scales. Leaves numerous, linear, all radical or crowded near the base of the stem, with broad imbricate sheathing bases. Flowering stem or scape usually long, panicled above and many-flowered, rarely short and few-flowered, usually densely silky or woolly. Flowers small, dioecious. Perianth persistent, 6-partite; segments subequal, connate at the base into a short hemispherical tube or distinct, spreading or reflexed. Male flowers: Stamens 6, affixed to the base of

the segments; filaments filiform; anthers oblong or linear-oblong. Rudimentary ovary present. Female flowers: Staminodia present. Ovary sessile, broadly ovoid or oblong, 1-celled with 3 parietal placentas, or 3-celled with the placentas in the axis; ovules numerous on each placenta; style very short; stigma 3-lobed. Fruit an indehiscent more or less fleshy oblong or ovoid or subglobose berry. Seeds several, ovoid or oblong, straight or curved, terete or angular; testa black, crustaceous; embryo small, cylindric; albumen fleshy.

A small genus of 15 or 16 species, with its headquarters in New Zealand, but with 1 species in south-eastern Australia and Tasmania, 1 in Fiji, 2 or 3 in the Sandwich Islands, and 1 in antarctic America. In New Zealand it forms a prominent part of the vegetation, especially in the northern forests, to which one or two of the species often give a peculiar aspect. The species are by no means easy of discrimination, partly from a certain amount of similarity in the foliage, and partly from the flowers being dioecious, thus making it difficult to match the sexes. When dealing with fresh specimens these difficulties in great measure disappear, particularly if due attention is paid to the structure of the ovary and the size and shape of the ripe fruit, both of which afford excellent characters. The student will find some valuable remarks on this point in Mr. Kirk's notes on the genus, published in Trans. N.Z. Inst., vol. iv, pp. 241–47. With respect to the remarkable diversity existing in the genus in the placentation of the ovary, reference should be made to the "Flora Antarctica," vol. ii, p. 357.

In the following arrangement I have adopted Hooker's identification of the two species originally described by Cunningham. But Cunningham's diagnoses, such as they are, do not satisfactorily match Hooker's plants, and it has been suggested that he had other species in his mind. The question is one which cannot be settled, if settled at all, without reference to Cunningham's collections, all of which are outside the Dominion, and beyond my reach. But taking into account Hooker's remarks in the "Flora of New Zealand" (vol. i, p. 251), where he says, "Cunningham confused all the species and sexes, examined none, and referred at random to Banks and Solander's drawings and notes, substituting names of his own for theirs," it appears highly doubtful whether such an examination would be at all conclusive. An alteration of the present nomenclature, which has received universal acceptance, would be a matter much to be deplored.

I have had much trouble with the species, 10 in all, described by Colenso in the Trans. N.Z. Inst. Unfortunately, few of them are represented by named specimens in his herbarium; and his descriptions are so vague, and so much overloaded with trivial details, that it is difficult to come to an opinion respecting them. But I can see no grounds for supposing that they are really distinct, or represent anything more than individual differences.

A. Berry 1-celled. Ovules attached to 3 parietal placentas.

Very small, subalpine. Leaves ¾–1 in., terete or canaliculate. Flower solitary .. .. 1. *A. subulata.*

Small, subalpine. Leaves 1–8 in., glabrous or scaly. Scape few-flowered. Berry oblong, ⅓–½ in. long .. .. .. 2. *A. linearis.*

Leaves 2–5 ft. × ½–1 in., glabrous or silky. Scape panicled, many-flowered; female prostrate in fruit. Berry globose, ⅕ in. diam. Seeds terete .. .. 3. *A. Cunninghamii.*

B. Berry 3-celled. Ovules attached to the inner angles of the cells.

* Perianth not enlarged or coloured in fruit.

Leaves 2–6 ft. × ½–1½ in., not conspicuously 3-nerved. Female scape stout, erect in fruit. Flowers ¼ in. long. Berry ⅓ in. long, ovoid, purplish-black. Seeds angled .. .. .. 4. *A. Banksii.*

Leaves 3–6 ft. × ¾–1¾ in., conspicuously 3-nerved and plaited. Female scape prostrate in fruit. Flowers ¼ in. long. Berry ⅓ in. diam., globose, red .. .. 5. *A. trinervia.*

Leaves 2–5 ft. × 1½–2½ in., conspicuously 3-nerved, not plaited. Flowers large, narrow, ½ in. long. Female scape not prostrate in fruit. Berry ⅘ in. diam., globose, red .. .. .. 6. *A. Solandri.*

** Perianth enlarged in fruit, coloured within.

Leaves 2–6 ft. × 1½–4 in., 3-nerved. Flowers ⅓ in. long, dark purplish-green. Female scape very stout, erect in fruit. Berry ovoid-globose, ½–⅔ in. diam., orange-yellow	7. *A. nervosa.*
Leaves 2–3 ft. × 1–1½ in., rigid and coriaceous, silky on both surfaces, often villous	8. *A. Cockaynei.*
Leaves 9–30 in. × ½–1½ in., almost glabrous above, silvery-white beneath. Flowers sunk among the upper foliage-leaves ..	9. *A. Petriei.*
Leaves 6–12 in. × ⅕–¼ in., bronzy to glaucous-green above, shaggy with white tomentum beneath. Flowers sunk among the upper foliage-leaves	10. *A. nivicola.*

1. **A. subulata** *Cheesem. in Subantarct. Is. of N.Z.* ii (1909) 429.—A small densely tufted and compacted little herb, with the habit of *A. linearis* but much smaller. Rhizome long and wiry, wide-creeping, much branched, thickly covered with the decaying bases of the old leaves, and forming with the long stringy roots a closely matted turf from 1 to 3 in. deep or more. Leaves small, ¾–1 in. long, erect or a little curved, pale and sheathing at the base, bright-green and shining above, terete or obscurely canaliculate, cylindric and acute at the tip; sheaths membranous, hyaline, clothed with silvery erect or appressed scales. Scape very short, solitary, terminal. Flower solitary, similar to that of *A. linearis*, but smaller. Fruit unknown.—A. linearis *var.* subulata *Hook. f. Fl. Antarct.* i (1844) 76.

Auckland and Campbell Islands: Wet peaty places on the hills, not uncommon, *Hooker, Cockayne, B. C. Aston! J. S. Tennant! R. M. Laing!* Stewart Island: Fraser Peaks, *Cockayne.*

This differs much in foliage from all states of *A. linearis*, which has leaves from 1–8 in. in length by $\frac{1}{10}$–¼ in. broad, channelled above and keeled below, more or less sulcate or grooved, and with the midrib and margins clothed with narrow hyaline scales. In *A. subulata* the leaves are seldom more than ¾ in. long by $\frac{1}{30}$ in. broad, terete or canaliculate above, smooth and glabrous except the sheaths. I have seen only very imperfect flowering specimens.

2. **A. linearis** *Hook. f. Fl. Antarct.* i (1844) 76.—A small densely tufted herb. Rhizome creeping, branched, clothed with the shaggy bases of the old leaves. Leaves terminating the branches of the rhizome, all radical, crowded, spreading, 1–8 in. long, $\frac{1}{10}$–¼ in. broad, narrow-linear, acute or acuminate, sheathing at the base, thick and coriaceous, nerved, often channelled above, slightly keeled beneath; margins recurved; both surfaces clothed when young with silvery or reddish-brown erect or appressed scales, becoming almost glabrous when old; sheaths broad, appressed, membranous, scarious, thickly covered with narrow hyaline silvery scales. Male flowers: Scape slender, equalling the leaves or shorter than them, simple or forked, 3–9-flowered; bracts 1–2, linear-elongate; pedicels rather long, slender. Perianth-segments silky externally, spreading or reflexed, knobbed at the tip. Filaments much shorter than the segments; anthers oblong. Rudimentary ovary broad, narrowed into a short thick style. Female flowers: Scape very short, almost concealed at the base of the leaves, 1–5-flowered. Perianth-segments longer and narrower, erect. Staminodia present, minute. Ovary large, narrow oblong-ovoid, 1-celled; stigma-sessile, 3-lobed; ovules numerous, attached in 2 series to 3 parietal placentas. Berry large for the size of the plant, ⅓–½ in. long, narrow-oblong, obscurely trigonous, fleshy, red. Seeds obovoid, not angled, smooth, black, shining.—*Handb. N.Z. Fl.* (1864) 284; *Cheesem. Man. N.Z. Fl.* (1906) 710. A. minima *Col. in Trans. N.Z. Inst.* xxviii (1896) 611.

** Perianth enlarged in fruit, coloured within.

ASTELIA according to Skottsberg.

^

North and South Islands, Stewart Island, Auckland and Campbell Islands: Moist ground in subalpine localities from the East Cape and Ruapehu southwards, not uncommon. Usually from 3000 to 5000 ft., but descends to sea-level in Stewart Island and the Auckland Islands. November–January.

3. **A. Cunninghamii** *Hook. f. Fl. Nov. Zel.* i (1853) 259.—A densely tufted species, epiphytic or terrestrial. Leaves numerous, 2–5 ft. long, ½–1 in. broad at the middle, drawn out into a long-acuminate point, contracted below, and then gradually widened into a broad sheathing base, rigid and coriaceous, glabrous or sparingly silky above, clothed with a thin silvery pellicle beneath; midrib and margins silky; nerves 10–12, usually one stronger than the rest on each side of the midrib, or sometimes a prominent bundle of 2–3 placed close together; margins recurved; sheathing base clothed with long dense white silky hairs. Male flowers: Scape 1–3 ft. long, very slender at the base, stouter above, trigonous, shaggy throughout with silky white hairs, panicled above; branches numerous, slender, often flexuous and interlaced; bracts long, leafy. Flowers numerous, small, ⅙ in. long, greenish-yellow or reddish-yellow or maroon. Perianth-segments lanceolate, acuminate, spreading or reflexed, the 3 outer rather larger than the inner. Stamens about ½ as long as the segments; anthers small, broadly oblong. Female flowers: Scape shorter, with a smaller and more closely branched panicle, branches shorter and more erect. Flowers rather smaller; segments not so spreading. Ovary ovoid-globose, 1-celled; ovules attached to 3 parietal placentas. Berry red, globose, ⅕ in. diam. Seeds linear-oblong, curved, terete, not angled.—*Handb. N.Z. Fl.* (1864) 283; *Cheesem. Man. N.Z. Fl.* (1906) 710. A. polyneuron *Col. in Trans. N.Z. Inst.* xiv. (1882) 333. (?) A. graminifolia *Col. l.c.* xix (1887) 267. Hamelinia veratroides *A. Rich. Fl. Nouv. Zel.* (1832) 158, t. 24 (*excl. fig.* c, d).

Var. **Hookeriana** *T. Kirk in Trans. N.Z. Inst.* iv (1872) 244.—Smaller and more slender, seldom exceeding 3 ft. Scape very slender; branches of male panicle seldom interlacing. Flowers rather smaller, claret-coloured. Berry nearly black, placentas very feebly developed.

North Island: Abundant in woods throughout. South Island: Nelson—Near Collingwood, *H. H. Travers;* Westport, *W. Townson!* Charlestown, *T. Kirk!* Sea-level to 3500 ft. *Kowharawhara.* December–January; ripe fruit November–December. Var. *Hookeriana:* Lava-fields on the Auckland Isthmus, Rangitoto Island, Little Barrier Island, &c. April–June; ripe fruit May–June.

Very near to *A. Banksii* in habit and general appearance, but widely differing in the 1-celled ovary and small globose berry with terete seeds. I have quoted A. Richard's *Hamelinia veratroides* as a synonym, his drawing of the female panicle exactly corresponding; but the section of the ovary given is that of *A. Banksii*, probably through some confusion of specimens.

4. **A. Banksii** *A. Cunn. Precur.* (1836) n. 296.—A large densely tufted terrestrial or rupestral species. Leaves very numerous, closely packed, erect, 2–6 ft. long, ½–1½ in. broad at the middle, narrow-linear, tapering into a long-acuminate point, narrowed below and then gradually expanded into a broad sheathing base, glabrous or slightly scurfy above, clothed with a thin silvery pellicle beneath, with 3–6 distinct and equally prominent nerves on each side of the midrib; margins recurved; sheathing base most densely clothed with long soft silky hairs. Male flowers: Scape slender at the base, stouter above, trigonous, excessively shaggy with dense white silky hairs, panicled; branches numerous, slender, often flexuous, 4–9 in. long; bracts at the base leafy, with long slender points. Flowers

many, about ¼ in. long; perianth-segments ovate-lanceolate, acuminate, spreading, the 3 outer larger than the inner. Stamens shorter than the segments; filaments subulate; anthers oblong. Female flowers: Scape shorter and stouter; branches shorter, crowded, more erect. Flowers smaller; perianth-segments ovate-oblong, acute, erect. Ovary ovoid-conical, 3-celled; ovules pendulous from the inner angle of each cell; stigmas 3, sessile. Berry ovoid, ⅓ in. long, purplish-black when fully ripe, reddish-purple when immature. Seeds sharply angled; testa black.—*Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 260; *Handb. N.Z. Fl.* (1864) 284; *Cheesem. Man. N.Z. Fl.* (1906) 711.

Rec. C.M. 4: 1935: 111

North Island: From the North Cape to Hawke's Bay and Taranaki; usually near the coast. South Island: Vicinity of Westport, *W. Townson!* Sea-level to 2500 ft. April; ripe fruit February–March.

Usually taller and stouter than *A. Cunninghamii*, with larger broader leaves, larger flowers, and much stouter female scape, erect in fruit. The ovary is essentially different, being 3-celled, with the ovules attached to the inner angles of the cells; and the large ovoid berry, with its angled seeds, is altogether unlike the small globose one of *A. Cunninghamii*, with its terete seeds. It is an abundant plant on the coast-line of the northern half of the North Island, often forming a large portion of the undergrowth on wooded headlands or steep declivities near the sea.

5. **A. trinervia** *T. Kirk in Trans. N.Z. Inst.* iv (1872) 246.—A large densely tufted terrestrial species. Leaves numerous, 3–6 ft. long or even more, ¾–1¾ in. broad at the middle, tapering into a long attenuated point, narrowed below and then gradually expanded into a broad sheathing base, not so coriaceous as in *A. Banksii*, pale-green, plaited, glabrous above, clothed with a thin silvery pellicle beneath, conspicuously 3-nerved with less evident nerves between; margins broadly recurved; sheathing base clothed with long white silky hairs. Male flowers: Scape long, slender, densely shaggy with white silky hairs, panicled; branches slender, exuous and often interlaced, 6–12 in. long or more; bracts large, foliaceous. Flowers numerous, ¼ in. long; perianth-segments lanceolate, acuminate, spreading. Stamens shorter than the segments; filaments slender; anthers oblong. Female flowers: Scape as in the male but panicle smaller with fewer, shorter, and more erect branches. Flowers smaller; perianth-segments shorter, erect. Ovary globose, 3-celled; ovules pendulous from the inner angles of the cells; stigmas 3, sessile. Fruiting-scape usually prostrate. Berry globose, ⅓ in. diam., bright-red. Seeds sharply angled, testa black.—*Cheesem. Man. N.Z. Fl.* (1906) 712; *Cockayne Veg. N.Z.* (1921) t. 30. see Skotts. l.c. p. 63.

North Island: In woods from the North Cape to Wellington, very plentiful north of the East Cape and Taupo. South Island: Marlborough—Rai Valley, *J. H. Macmahon!* vicinity of Westport, *W. Townson!* Sea-level to 3000 ft. *Kauri-grass.* March–May; ripe fruit February and March.

Separated from *A. Banksii* by the larger size and less rigid habit, broader and softer pale-green conspicuously 3-nerved and plaited leaves, prostrate fruiting-scape, and red globose berry. It is an abundant and conspicuous plant in the kauri forests of the North Auckland Peninsula, often forming a considerable proportion of the undergrowth. It is seldom seen on trees.

6. **A. Solandri** *A. Cunn. Precur.* (1836) n. 297.—Large, densely tufted, often forming immense clumps on the limbs and trunks of forest-trees or on rocks. Leaves very numerous, spreading and recurved, 2–5 ft. long, 1½–3 in. wide at the middle, linear-ensiform, narrowed above into a long acuminate point, suddenly expanded below into a sheathing base sometimes 4–5 in. across, conspicuously 3-nerved, glabrous and deeply channelled in

front, keeled and with a thin white silvery pellicle beneath ; sheathing base black, at the extreme base white and fleshy, glabrous or clothed with copious long white silky hairs. Male flowers : Scape stout, much shorter than the leaves, densely silky below, paniculed ; branches few, 5–8, simple, 3–9 in. long, 1 in. broad with the flowers on ; bracts at the base of the branches very large, leafy, acuminate. Flowers very numerous, densely crowded, $\frac{1}{2}$ in. long, pale lemon-yellow ; pedicels slender, $\frac{1}{4}$ in., each subtended by a linear bract. Perianth 6-partite ; segments reflexed, linear, obtuse, silky externally. Stamens as long as the segments ; anthers linear, erect, sagittate at the base. Female flowers : Scape [illegible] ed as in

[illegible], dark-green or greenish-black. Male flowers : Scape very stout, erect or inclined, 6 in. to 2 ft. long, thickening upwards to the base of the panicle, where it is sometimes $1\frac{1}{2}$ in. diam., obtusely triquetrous ; lower portion shaggy with copious long silky hairs ; upper part silky or glabrate. Panicle 4–15 in. long, much-branched ; bracts very long, lanceolate, gradually narrowed upwards into long attenuated points. Flowers $\frac{1}{3}$–$\frac{1}{2}$ in. diam. ; pedicels $\frac{1}{10}$–$\frac{1}{6}$ in. long. Perianth-segments ovate-lanceolate, spreading, ultimately reflexed. Stamens as long as the segments ; filaments subulate ; anthers broadly oblong. Female flowers : Scape as in the male, but shorter ; panicle much shorter and more compact ; branches fewer, short, stiff, erect. Flowers smaller, crowded ; pedicels very short. Perianth-segments smaller. Ovary broadly conical, faintly grooved, 3-celled ; ovules

many, about $\frac{1}{4}$ in. long; perianth-segments ovate-lanceolate, acuminate, spreading, the 3 outer larger than the inner. Stamens shorter than the segments; filaments subulate; anthers oblong. Female flowers: Scape shorter and stouter; branches shorter, crowded, more erect. Flowers smaller; perianth-segments ovate-oblong, acute, erect. Ovary ovoid-conical, 3-celled; ovules pendulous from the inner angle of each cell; stigmas 3, sessile. Berry ovoid, $\frac{1}{3}$ in. long, purplish-black when fully ripe, reddish-purple when immature. Seeds sharply angled; testa black.—*Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 260; *Handb. N.Z. Fl.* (1864) 284; *Cheesem. Man. N.Z. Fl.* (1906) 711.

COLLOSPERMUM Skottsberg.

Racemi omnes simplices. Flores ♂ quam ♀ valde majores, tepalis longissimis tenuissimis. Antherae lineares sagittatae, basifixae, immobi es, persistentes. Ovarium triloculare, placentis in dissepimentorum parte interiore evolutis. Semina plerunque pilis mucilaginosi e funiculo ortis usque ad maturitatom cineta.

   B. Folia 1-1.5 cm. lata . . . . microspermum
11. Nana, foliis 10-30 cm. longis . . . . . spicatum

May; ripe fruit February and March.

Separated from *A. Banksii* by the larger size and less rigid habit, broader and softer pale-green conspicuously 3-nerved and plaited leaves, prostrate fruiting-scape, and red globose berry. It is an abundant and conspicuous plant in the kauri forests of the North Auckland Peninsula, often forming a considerable proportion of the undergrowth. It is seldom seen on trees.

6. **A. Solandri** *A. Cunn. Precur.* (1836) n. 297.—Large, densely tufted, often forming immense clumps on the limbs and trunks of forest-trees or on rocks. Leaves very numerous, spreading and recurved, 2–5 ft. long, $1\frac{1}{2}$–3 in. wide at the middle, linear-ensiform, narrowed above into a long acuminate point, suddenly expanded below into a sheathing base sometimes 4–5 in. across, conspicuously 3-nerved, glabrous and deeply channelled in

front, keeled and with a thin white silvery pellicle beneath ; sheathing base black, at the extreme base white and fleshy, glabrous or clothed with copious long white silky hairs. Male flowers : Scape stout, much shorter than the leaves, densely silky below, panicled ; branches few, 5–8, simple, 3–9 in. long, 1 in. broad with the flowers on ; bracts at the base of the branches very large, leafy, acuminate. Flowers very numerous, densely crowded, $\frac{1}{2}$ in. long, pale lemon-yellow ; pedicels slender, $\frac{1}{4}$ in., each subtended by a linear bract. Perianth 6-partite ; segments reflexed, linear, obtuse, silky externally. Stamens as long as the segments ; anthers linear, erect, sagittate at the base. Female flowers : Scape stout, branched as in the male ; but branches longer and more slender, sometimes 12–14 in. long by $\frac{3}{4}$ in. diam., usually drooping in fruit. Flowers much smaller ; perianth with a hemispherical tube closely surrounding the ovary ; segments reflexed. Ovary globose, 3-celled ; ovules numerous, attached to the inner angles of the cells. Berry rather small, $\frac{1}{5}$ in. diam., globose, bright-red. Seeds small, obovoid, slightly curved, not angled, black.—*Raoul Choix* (1846) 40 ; *Hook. f. Fl. Nov. Zel.* i (1853) 260 ; *Handb. N.Z. Fl.* (1864) 284 ; *Bot. Mag.* t. 5503 ; *Cheesem. Man. N.Z. Fl.* (1906) 712 ; *Cockayne Veg. N.Z.* (1921) t. 27, 29. A. microsperma *Col. in Trans. N.Z. Inst.* xvii (1885) 251. A. albicans *Col. l.c.* 252. A. hastata *Col. l.c.* xix (1887) 265.

North Island : Abundant in forests throughout. South Island : Marlborough—Queen Charlotte Sound, *Banks* and *Solander ;* Pelorus Valley, *J. Rutland, J. H. Macmahon !* Nelson—Common on the West Coast, from Collingwood and Westport southwards. Sea-level to 3000 ft. *Kahakaha.* January–February.

A very distinct species, at once known by the broad almost glabrous 3-nerved leaves with a nearly black sheathing base, by the densely placed flowers, the males being much longer and narrower than in any other species, and by the small red globose berry. It is a conspicuous plant in all the forest districts of the North Island, from its habit of growing perched high up on the limbs of tall forest-trees, where it forms huge tufts resembling the nests of some gigantic bird, for which, in fact, it was mistaken when first seen by Cook and his officers in 1769.

7. **A. nervosa** *Banks and Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 260.—A large and stout densely tufted plant, often forming extensive masses in moist forests or swampy ground. Leaves very numerous, spreading, 2–5 ft. or even up to 8 ft. long, 1–3 in. broad, or in large specimens as much as 4 in., linear-lanceolate or linear-ensiform, tapering upwards into an acuminate point, dilated at the sheathing base, coriaceous, many-nerved, one nerve on each side stouter than the rest and with the midrib often coloured red or purplish-red ; glabrous above or rarely silky, beneath more or less scurfy or clothed with silky appressed hairs, rarely nearly glabrous ; margins recurved, usually silky ; sheathing base densely villous with long silky hairs. Flowers sweet-scented, dark-green or greenish-black. Male flowers : Scape very stout, erect or inclined, 6 in. to 2 ft. long, thickening upwards to the base of the panicle, where it is sometimes $1\frac{1}{2}$ in. diam., obtusely triquetrous ; lower portion shaggy with copious long silky hairs ; upper part silky or glabrate. Panicle 4–15 in. long, much-branched ; bracts very long, lanceolate, gradually narrowed upwards into long attenuated points. Flowers $\frac{1}{3}$–$\frac{1}{2}$ in. diam. ; pedicels $\frac{1}{10}$–$\frac{1}{6}$ in. long. Perianth-segments ovate-lanceolate, spreading, ultimately reflexed. Stamens as long as the segments ; filaments subulate ; anthers broadly oblong. Female flowers : Scape as in the male, but shorter ; panicle much shorter and more compact ; branches fewer, short, stiff, erect. Flowers smaller, crowded ; pedicels very short. Perianth-segments smaller. Ovary broadly conical, faintly grooved, 3-celled ; ovules

many, attached to the inner angles of the cells. Berry globose or ovoid-globose, usually pointed at the tip, $\frac{1}{3}$ in. diam., bright orange-yellow. Fruiting-perianth cup-shaped, thin when ripe, coloured yellow within. Seeds 2–5 to each cell, smooth, black, sharply angled.—*Hook. f. Handb. N.Z. Fl.* (1864) 284; *Cheesem. Man. N.Z. Fl.* (1906) 713. A. grandis *Hook. f. ex T. Kirk in Trans. N.Z. Inst.* iv (1872) 245. A. fragrans *Col. in Trans. N.Z. Inst.* xv (1883) 333.

var. grandis (Hk.f. ex T. Kirk) C.+A. Trans. 56: 1926: 21

North and South Islands, Stewart Island: From the Bay of Islands southwards, abundant. Sea-level to 3000 ft. October–January.

var. sylvestris C.+A. l.c.

The most widely distributed species in New Zealand. Its nearest ally is *A. Cockaynei*, from which it cannot be separated by any strict line of demarcation. Ordinarily, however, *A. Cockaynei* can be distinguished by the smaller size and much more rigid leaves, which are usually silky on both surfaces, and occasionally even villous. In foliage *A. nervosa* approaches *A. trinervia*, but from that plant, and from all the large-leaved species, it is at once removed by the fruiting-perianth being enlarged and coloured within.

8. **A. Cockaynei** *Cheesem. n. comb.*—Very closely allied to *A. nervosa*, and possibly only a subalpine state, but smaller in all its parts, and with the foliage much more rigid and silky. Leaves numerous, 2 ft. 6 in. long or more, $1\frac{1}{3}$–$1\frac{1}{2}$ in. broad, linear or linear-ensiform, gradually narrowed into long acuminate points, dilated at the sheathing base; midrib stout, prominent beneath; half-way between the midrib and the margin is a stout rib composed of 2 almost coalescent veins; ribs often coloured red or purplish-red; upper surface of leaf usually with a thin easily detached silvery pellicle, and generally more or less clothed with silky appressed hairs, sometimes almost villous; under-surface paler, more or less scurfy, generally covered with white appressed scales or hairs, which are most plentiful along the margins; veins numerous, evident; sheathing base of leaves densely covered with long appressed silvery-white or tawny hairs. Flowers very similar to those of *A. nervosa*, but the panicles much smaller and with fewer branches, and the females much more compact. Berry ovoid or ovoid-globose, pointed at the tip, $\frac{1}{3}$ in. diam., fleshy, reddish-orange, enclosed in the persistent cup-shaped enlarged base of the perianth, which is often but not invariably coloured red within. Seeds 2–3 in each cell, black, angled.—A. nervosa *var.* montana *T. Kirk in Cheesem. Man. N.Z. Fl.* (1906) 714. A. montana *Cockayne in Bot. Survey Tongariro* (1908) 36 (*not of Seem.*).

North and South Islands, Stewart Island: Abundant in subalpine localities from Hikurangi, Mount Egmont, and Taupo southwards. 2500–5000 ft. December–January.

There can be no doubt that a direct passage can be traced from *A. Cockaynei* into *A. nervosa*. On the mountains of north-west Nelson I have several times satisfied myself on this point, and Mr. Petrie has come to the same conclusion as regards the Tararua Mountains (Trans. N.Z. Inst. xl (1908) 293–94). But the difference between the extreme state of *A. Cockaynei*, with its low tufts of greyish-white foliage shaggy from the abundance of silky hairs, and the highly developed form of *A. nervosa* formerly known as *A. grandis*, in which the leaves are almost glabrous, and frequently reach a height of 8 ft., with a width of over 4 in., is so pronounced that I cannot refuse to separate the two plants.

9. **A. Petriei** *Cockayne in Trans. N.Z. Inst.* xxxi (1899) 419.—Densely tufted, forming large patches in damp alpine meadows. Leaves 9–30 in. long, $\frac{1}{2}$–$1\frac{1}{2}$ in. broad, linear-ensiform or linear-subulate, gradually narrowed into a long acuminate point, expanded at the sheathing base, rigid and

coriaceous, pale-green and shining above, silvery-white beneath; veins conspicuous on both surfaces. Upper surface almost glabrous when mature, in the young leaves sparingly clothed with minute scurfy scales; under-surface with the spaces between the veins filled with a coating of silvery-white scales; basal sheaths white and fleshy at the base. Inflorescence consisting of a short stiff erect panicle 2–4 in. long sunk amongst the upper foliage-leaves, with few short branches subtended by broad bracts narrowed into long acuminate points. Flowers immature in my specimens, but the males are described by Cockayne as "crowded, very shortly pedicelled, strongly scented, semi-erect; perianth-segments linear or ligulate, purplish and yellow at the base; filaments stout; anthers black." The female inflorescence is said to be "shorter than the male; perianth-segments ovate, acute, sometimes trifid, pilose at the apex." Mature fruit not seen.

South Island: Nelson—Buckland Peaks, *Petrie!* Canterbury—Mount Peel, *H. H. Allan!* Mount Rolleston, *Cockayne!* Walker's Pass, *R. Brown* and *Cockayne.* Westland—Kelly's Hill, *Petrie* and *Cockayne.* Otago—Humboldt Mountains, *Cockayne;* Lake Harris Saddle, *W. A. Thomson!* Altitudinal range from 3500 to 4500 ft.

A very remarkable little plant, the exact systematic position of which must remain doubtful until perfect flowers and fruit have been obtained. Mr. W. A. Thomson, who has supplied me with good specimens of the foliage, informs me that it blooms very seldom, and Mr. H. H. Allan and Dr. Cockayne make the same observation.

10. **A. nivicola** *Cockayne n. sp. ined.*—A tufted herb forming extensive patches in moist alpine hollows. Leaves 6–12 in. long, $\frac{1}{5}$–$\frac{1}{4}$ in. broad at the middle, coriaceous but flexible, gradually tapering upwards into an acute apex, keeled towards the base and stem-clasping, and then suddenly expanded into a thin and membranous almost transparent sheath; upper surface pale bronzy-green to glaucous-green, covered with a membranous pellicle or more or less silky-tomentose; under-surface clothed with thin shaggy or villous whitish tomentum; veins variable in number, usually about 6 on each side of the rather slender midrib, which is sunken above but prominent beneath. Flowers not seen. Fruiting-panicle (one specimen alone seen) very short, $\frac{3}{4}$ in. long and about as wide, nearly sessile among the bases of the uppermost leaves; branches few, short, densely compacted. Berry apparently ovoid-globose, $\frac{1}{4}$–$\frac{1}{3}$ in. long, reddish-orange, sunk in the persistent base of the perianth.

South Island: Mount Cook district, altitude 4500 ft. and upwards, *Cockayne!*

I am indebted to Dr. Cockayne for two specimens of this curious little plant, accompanied by MSS. notes, of which I have availed myself in drawing up the above description. This will probably need amendment when a full suite of specimens has been obtained.

5. **DIANELLA** Lam.

Glabrous perennial herbs. Rootstock often branched. Leaves numerous, crowded at the base of the stem, linear, distichous, equitant and sheathing at the base. Flowers pedicellate, nodding, laxly cymose; cymes arranged in a broad open terminal panicle. Perianth marcescent; segments 6, distinct, spreading. Stamens 6, hypogynous, or the 3 inner affixed to the base of the segments; filaments thickened; anthers erect or recurved, basifixed, opening by terminal pores or short longitudinal slits. Ovary sessile or shortly stalked, 3-celled; ovules 4–8 in each cell;

See Skottsberg. Occ. Papers B.P. Bish. Mus. XIII (18) 1937 : 234.
" Medd. Göt Bot. Trad XV p. 338.

style filiform; stigma minute. Fruit a globose berry. Seeds few, ovoid or compressed; testa black, smooth and shining; albumen fleshy; embryo small, linear.

Species 11 or 12, chiefly Australian, but found also in New Zealand, Polynesia, tropical Asia, and the Mascarene Islands. The single New Zealand species extends to Norfolk Island and several parts of Polynesia.

1. **D. intermedia** *Endl. Prodr. Fl. Ins. Norfolc.* (1833) 28.—Rhizome stout, woody, creeping, usually with underground runners. Leaves numerous, crowded at the top of the rhizome, distichous and sheathing at the base, 1½–3 ft. long or more, ½–¾ in. wide, narrow linear-ensiform, acute or acuminate, keeled, margins and keel minutely scabrid. Panicle 6–24 in. long, much branched; peduncles and pedicels slender, the latter curved. Flowers small, ¼–⅓ in. diam.; greenish or purplish-white. Perianth-segments oblong, spreading; the 3 outer usually 5–6-nerved; the 3 inner rather broader, 3-nerved. Filaments expanded into a yellow or orange struma often thicker than the anther; anther linear-oblong, yellow. Berry ½–¾ in. long, broadly oblong, bright-blue.—*A. Cunn. Precur.* (1836) n. 300; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 255; *Handb. N.Z. Fl.* (1864) 283; *Cheesem. Man. N.Z. Fl.* (1906) 715. D. nigra *Col. in Trans. N.Z. Inst.* xvi (1884) 339. D. reflexa *Col. l.c.* xxvii (1895) 396.

var. norfolkensis n.var. Brown : Kauri Gulch - acc. paper. Bish. Mus. IX 4 : 1930

North and South Islands: From the Three Kings Islands and the North Cape to Foveaux Strait, abundant. Sea-level to 2500 ft. *Turutu.* November–December.

Allan. TNZI. 76 (1947) 594 Skottsberg - XIII 18 (1937) 254

6. **PHORMIUM** Forst. 1776 J.R.A.G. p. 47. t. 24

Tall rigid and coriaceous herbs. Rhizome short, stout, branched, with thick and fleshy perpendicular rootlets. Leaves all radical, long, linear-ensiform, equitant and distichous, exceedingly tough and coriaceous. Flowering stem or scape tall, leafless, with alternate bracteate branches at the top; bracts caducous. Flowers pedicelled on the branches of a terminal panicle, dull-red or yellow; pedicels jointed. Perianth tubular, curved; segments 6, connate at the base, free but connivent above; the 3 outer lanceolate, erect, acute; the 3 inner rather longer, with spreading tips. Stamens 6, inserted at the base of the segments and longer than them; filaments filiform; anthers linear-oblong. Ovary sessile, oblong, obtusely trigonous, 3-celled; style slender, equalling or exceeding the stamens, declinate; stigma small, capitate; ovules numerous in each cell. Capsule subcoriaceous or almost membranous, oblong or linear, trigonous or almost terete, straight or twisted, loculicidally 3-valved. Seeds many, oblong, greatly compressed; testa black, shining.

Phormium, or the "New Zealand flax," is a very remarkable genus of 2 species, confined to New Zealand and Norfolk Island. Its value as producing one of the strongest and most durable fibres of the vegetable kingdom is too well known to require recapitulation here.

Leaves 3–9 ft., dark-green, glaucous beneath; margins usually bordered with a coloured line. Flowers dull-red. Capsule short, erect or inclined, trigonous, 2–4 in. long	1. *P. tenax.*
Leaves 2–5 ft., pale-green, less rigid; margins seldom coloured. Flowers yellowish. Capsule long, pendulous, cylindrical, terete, twisted, 4–7 in. long	2. *P. Colensoi.*

1. **P. tenax** *Forst. Char. Gen.* (1776) 48.—Leaves 3–9 ft. long or more, 2–5 in. broad, linear-ensiform, acute or acuminate, apex slit when mature, distichous and equitant at the base, flat above, keeled, very tough and coriaceous, dark-green above, often glaucous beneath, margins and midrib bordered with a red or orange line. Scape very variable in height, 5–15 ft., glabrous, terete, reddish-purple. Flowers numerous, 1–2 in. long, usually dull-red. Inner perianth-segments erect or slightly recurved at the tip. Capsule erect or inclined, stout, trigonous, 2–4 in. long, not twisted.—*A. Rich. Fl. Nouv. Zel.* (1832) 153; *A. Cunn. Precur.* (1836) n. 304; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 256; *Handb. N.Z. Fl.* (1864) 286; *Cheesem. Man. N.Z. Fl.* (1906) 716.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Abundant throughout, especially in lowland swamps and alluvial grounds. Sea-level to 4500 ft. *New Zealand Flax; Harakeke; Korari* (the scape); *Muka* (the fibre). November–January.

A familiar plant to all residents in New Zealand, and, with the exception of certain well-known timber-trees, probably of more economic importance than any other indigenous species. For information as to its value as a fibre-plant, and for full particulars as to the mode of preparing the fibre, its microscopical and chemical properties, &c., reference should be made to "*Phormium tenax* as a Fibrous Plant," edited by Sir James Hector, and issued by the Geological Survey Department (second edition, Wellington, 1889). This publication also contains a bibliography of the numerous official reports, memoirs, and short papers which have been published from time to time in reference to *Phormium*, several of them containing much valuable information.

P. tenax varies much in size, the colour of the leaf and the extent to which it is recurved and split at the tip, the tint of the coloured line bordering the margins and midrib, the colour of the flowers, and the size of the capsule. Some of the varieties also differ considerably in the strength of the fibre. Considering the economic importance of the plant, it is singular that few systematic attempts have been made to collect the whole of the varieties and cultivate them side by side in one at least of the public gardens of the Dominion. Until this is done it is practically impossible to describe them in a scientific manner. Isolated descriptions of a few, without comparison with the rest, would be of little use. Some varieties with the leaves variegated in a riband-like manner with white or creamy-yellow, and others with bronzy or purplish foliage, are largely cultivated for ornamental purposes, but are not usually capable of being reproduced by seed.

2. **P. Colensoi** *Hook. f. in Raoul Choix* (1846) 41.—Much smaller and less rigid than *P. tenax*. Leaves 2–5 ft. long, rarely more, 1–2½ in. broad, acuminate, apex sometimes conspicuously split, but usually much less so than in *P. tenax*, pale-green, seldom glaucous, margins and midrib not usually bordered with a coloured line. Scape 2–7 ft. high, much more slender and with a smaller panicle, green. Flowers 1–1½ in. long; the outer segments yellow or yellowish-red, the inner green or greenish-yellow, with evidently recurved tips. Capsule long, pendulous, cylindrical, terete, twisted, 4–7 in. long.—*Hook. f. Handb. N.Z. Fl.* (1864) 286. P. Cookianum *Le Jolis in Bull. Soc. Hort. Cherb.* (1848) 71, *and in Lond. Journ. Bot.* vii (1848) 536; *Cheesem. Man. N.Z. Fl.* (1906) 716. P. Hookeri *Gunn. in Bot. Mag.* (1888) t. 6973.

North and South Islands, Stewart Island: Not uncommon from the North Cape southwards. Sea-level to 4500 ft. *Mountain-flax; Whaririki.* November–January.

The small size, pale colour, yellowish flowers, and long twisted capsules distinguish this from *P. tenax;* but it is in some respects an ill-defined species, including several forms respecting which additional information is required. One of these, figured in the "Botanical Magazine" under the name of *P. Hookeri*, is remarkable for its flaccid much-recurved leaves with long fissured tips. Sir J. D. Hooker considers that it is more different from *P. tenax* and *P. Colensoi* than they are from one another; but his plate

shows the floral characters to be very similar to those of *P. Colensoi*. A curious sport discovered by the late Bishop Williams at Blackhead, Taranaki, and described by him in Trans. N.Z. Inst., xxxvi (1904), 333, t. 25, is remarkable from the flowers being either accompanied by clusters of leafy bracts or altogether replaced by them. A plant grown in my own garden produced these leafy bracts, many of which were 18 in. long, for 4 or 5 years in succession, but in one year only did flowers appear as well.

Chrysobactron Hook.

7. BULBINELLA Kunth. 1843

Perennial herbs. Rootstock short, stout, with numerous fleshy almost tuberous roots. Leaves all radical, numerous, linear, sheathing at the base, often fleshy. Scape simple or very rarely branched, naked, terminating in a dense many-flowered raceme. Flowers rather small, yellow or white. Perianth marcescent, 6-partite; segments subequal, distinct or slightly connate at the base, 1-nerved. Stamens 6, hypogynous or adnate to the base of the segments; filaments subulate-filiform; anthers versatile. Ovary subglobose, 3-celled; style filiform; stigma small, capitate, obscurely 3-lobed; ovules 2 in each cell. Capsule broadly ovoid or subglobose, membranous, 3-celled, loculicidally 3-valved. Seeds few, often compressed and triquetrous; testa black.

About 16 species are known, all confined to South Africa with the exception of the three described herein. In my memoir on the Systematic Botany of the Islands to the South of New Zealand (p. 464) I have expressed the opinion that Hooker's genus *Chrysobactron* should be revived for the purpose of receiving the New Zealand species; and I am not at all sure that this course will not be ultimately adopted. So far, however, I find that the two groups are not separated by very pronounced characters, and I therefore postpone making any change until a careful investigation can be made.

* Flowers dioecious.

Tall and stout. Leaves often 2 in. broad. Scape 2–3 ft. high .. 1. *B. Rossii.*
Much smaller. Leaves ensiform, 5–9 in. long, ½–1 in. broad. Scape 6–12 in. .. .. 2. *B. Gibbsii.*

** Flowers hermaphrodite.

Slender, usually 1–2½ ft. high; leaves ⅛–¾ in. broad .. .. .. 3. *B. Hookeri.*

(Hook.f.) Bak.

1. **B. Rossii** *Benth. and Hook. f. Gen. Plant.* iii (1880) 784.—A stout perennial herb 9 in. to 3 ft. high; stems sometimes 1½ in. diam. at the base. Leaves numerous, all radical, outer spreading or recurved, inner ascending, 6 in. to 2 ft. long, ½–2 in. broad, broadly ensiform, obtuse or subacute, fleshy, glabrous, concave above, finely striate. Scape stout, erect, terete, ¼–⅓ in. diam. Raceme very stout and dense, 3–6 in. long, 1–2½ in. diam. Flowers numerous, very densely crowded, bright-yellow, polygamo-dioecious, ⅓ in. diam.; pedicels slender, erect, ½–¾ in. long; bracts lanceolate. Perianth-segments linear-oblong or oblong-ovate, obtuse, spreading in the male flowers, more erect in the female. Stamens of the male flowers shorter than the segments; filaments subulate, terete, glabrous; anthers oblong. Ovary of the females broadly ovoid; style short, stout; stigma small, obscurely lobed. Capsule ¼–⅓ in. long, broadly ovoid. Seeds usually 2 in each cell, trigonous; testa black, shining.—*Cheesem. Man. N.Z. Fl.* (1906) 717. Chrysobactron Rossii *Hook. f. Fl. Antarct.* i (1844) 72, tt. 44, 45. Anthericum Rossii *Hook. f. Handb. N.Z. Fl.* (1864) 285.

Auckland and Campbell Islands: Abundant. December–January.

A most magnificent plant, excellently figured and described in the "Flora Antarctica." Sir J. D. Hooker states that he has seen a specimen between 3 ft. and 4 ft. high, having 3 crowns of leaves, and bearing no less than 7 racemes of flowers. In some localities on Campbell Island it forms so large a proportion of the vegetation, and the golden-yellow flowers are so abundantly produced, that its presence can be observed at a distance of more than a mile from the shore.

Bulbine in D.Z. acc. to Hutch. p. 88

(Gen.) Cheesm.

2. **B. Gibbsii** *Cockayne Bot. Survey Stewart Is.* (1909) 42.—A perennial herb 5–12 in. high, similar to *B. Rossii*, but much smaller in all its parts; stems seldom more than ½ in. diam. at the base. Leaves numerous, all radical, outer spreading and recurved, inner more erect, 5–9 in. long, seldom more, ½–1 in. broad, broadly ensiform, gradually tapering upwards into a narrow subacute or obtuse tip, fleshy, glabrous, concave above, convex beneath. Scape exceeding the leaves, 5–12 in. long, much more slender than in *B. Rossii*, terete. Racemes not remarkably dense, 2–3½ in. long; pedicels ¾ in., rarely more. Flowers polygamo-dioecious, much as in *B. Rossii*, but smaller and not so brightly coloured.—Chrysobactron Gibbsii *Cockayne N.Z. Plants and their Story* (1919) 193.

STEWART ISLAND: Bogs and subalpine meadows, abundant, *Thomson, Cockayne! Guthrie-Smith!* Sea-level to 2500 ft.

Clearly a distinct species, much more closely allied to *B. Rossii* than to *B. Hookeri*. I have seen but few specimens; and it is much to be regretted that Dr. Cockayne, when describing the plant, did not give a more adequate description.

(Col.) Benth & Hook f.

3. **B. Hookeri** *Benth. and Hook. f. Gen. Plant.* iii (1880) 784.—Very variable in size, usually from 1 to 2 ft. high, but sometimes attaining 3 ft., and occasionally dwarfed to 3 or 4 in. Leaves numerous, narrower in proportion than in *B. Rossii*, ⅙–¾ in. broad, narrow-linear, gradually tapering upwards, channelled in front, glabrous, green or glaucous-green. Scape much more slender than in *B. Rossii*; racemes not so dense-flowered, varying in length from 1 to 10 in. Flowers ⅓ in. diam., bright-yellow, hermaphrodite; pedicels slender, longer or shorter than the lanceolate bracts. Perianth-segments linear-oblong, obtuse, spreading. Stamens ¾ the length of the segments; filaments very slender, glabrous. Capsule oblong, ¼ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 718; *Ill. N.Z. Fl.* ii (1914) t. 202. Chrysobactron Hookeri *Col. in Hook. Ic. Plant.* (1852) t. 817; *Bot. Mag.* (1851) t. 4602; *Hook. f. Fl. Nov. Zel.* i (1853) 255. Anthericum Hookeri *Col. in Hook. f. Handb. Fl. N.Z.* (1864) 286. Trans. 44 33.

Var. **angustifolia** *Cockayne and Laing in Trans. N.Z. Inst.* xliii (1911) 366.—Smaller in all its parts than the type. Leaves narrower, ⅛–½ in. broad at the base, deeply concave, not glaucous. Racemes shorter and denser.

NORTH AND SOUTH ISLANDS, STEWART ISLAND: Mountain districts from Lake Taupo and Mount Egmont southwards, abundant. Sea-level to 4500 ft. October–January. Var. *angustifolia*: Dry mountain districts to the east of the Southern Alps, apparently plentiful.

One of the most widely distributed subalpine plants in the Dominion, everywhere present in damp peaty soil at elevations above 2000 ft. Of late years it has increased enormously in almost the whole of the open subalpine country along the chain of the Southern Alps, mainly through its power of resisting fire and from the fact that as a rule it is distasteful to stock.

Brown. 1810 276.

8. **ARTHROPODIUM** R. Br.

Tufted perennial herbs, with fleshy fibrous roots. Leaves radical or crowded near the base of the stem, linear or lanceolate, sheathing at the base. Scape or peduncle simple or branched above. Flowers in simple or branched racemes or panicles, white or purplish; pedicels slender, jointed at the middle, solitary or few together in the axil of a scarious bract. Perianth persistent but not twisted, 6-partite; segments distinct, spreading, 3-nerved, subequal or the inner rather broader. Stamens 6,

hypogynous or attached to the very base of the segments, shorter than the perianth; filaments bearded; anthers linear, erect, basifixed, introrsely dehiscent. Ovary sessile, 3-celled; ovules several in each cell; style filiform; stigma small. Capsule subglobose, loculicidally 3-valved. Seeds usually few in each cell, angular; testa black, smooth or minutely granulate.

Besides the 2 species found in New Zealand, both of which are endemic, there are 5 or 6 in Australia, and 1 in New Caledonia.

Tall and stout, 1–2½ ft. Leaves fleshy, 1–2 in. broad. Flowers ¾–1 in. diam.	1. *A. cirrhatum.*
Slender, 3–12 in. high. Leaves grassy, flaccid, $\frac{1}{10}$–¼ in. broad. Flowers ¼ in. diam.	2. *A. candidum.*

1. **A. cirrhatum** *R. Br. in Bot. Mag.* (1822) t. 2350.—A perfectly glabrous tufted herb 1–3 ft. high; root with copious long fleshy fibres. Leaves numerous, spreading, 1–2 ft. long, 1–2½ in. broad, lanceolate or oblanceolate, acute or acuminate, narrowed to an equitant and subdistichous base, flat or obtusely keeled, rather fleshy. Scape stout, terete, naked; panicle large, often 1 ft. long, deltoid, much branched; primary bracts broad, foliaceous. Flowers white, ¾–1 in. diam., 1–3 together along the branches of the panicle; pedicels $\frac{1}{3}$–⅔ in. long. Perianth-segments oblong-lanceolate, acuminate. Filaments filiform at the base, provided above the middle with a thickened densely woolly appendage, which is produced downwards into 2 woolly tails. Capsule oblong-globose, ⅓ in. long. Seeds black, opaque, angular.—*A. Cunn. Precur.* (1836) n. 299; *Raoul Choix* (1846) 40; *Hook. f. Fl. Nov. Zel.* i (1853) 254; *Handb. N.Z. Fl.* (1864) 285; *Cheesem. Man. N.Z. Fl.* (1906) 719. Anthericum cirratum *Forst. f. Prodr.* (1786) n. 148; *A. Rich. Fl. Nouv. Zel.* (1832) 155.

North Island: From the Three Kings Islands and the North Cape to Wellington, not uncommon, especially near the sea. South Island: Nelson—Takaka, *Kingsley;* West Wanganui, *Hursthouse.* Marlborough—Pelorus Sound, *Cockayne.* *Rengarenga.* November–December.

This differs from the other species of the genus in the woolly thickening at the middle of the filament being 2-lobed at the base, the lobes being revolute at the tip, somewhat after the fashion of a tendrill, from whence the specific name.

2. **A. candidum** *Raoul Choix* (1846) 14, t. 6.—A small slender glabrous herb 3–14 in. high; stem often swollen below the leaves and almost bulbous; roots long, fleshy. Leaves variable in length, 2–10 in. long, $\frac{1}{10}$–¼ in. broad, very narrow-linear, flat, grassy, membranous and flaccid. Scape very slender; raceme simple, rarely branched, usually overtopping the leaves. Flowers few or many, usually secund, solitary or the lower ones in twos or threes, white, ¼ in. diam.; pedicels slender, spreading or drooping; bracts long, linear-lanceolate, acuminate. Filaments naked at the base, then densely hairy almost up to the anther. Capsule globose, membranous, ⅙ in. diam. Seeds 2–3 in each cell, black, angled.—*Hook. f. Fl. Nov. Zel.* i (1853) 254; *Handb. N.Z. Fl.* (1864) 285; *Cheesem. Man. N.Z. Fl.* (1906) 719. A. reflexum *Col. in Trans. N.Z. Inst.* xviii (1886) 275. A. ramulosum *Col. l.c.* xxv (1893) 337.

North and South Islands: From Cape Colville southwards to Foveaux Strait, not uncommon. Sea-level to 3500 ft. November–January.

I cannot see upon what grounds Mr. Colenso has distinguished his two species. The type specimens in his herbarium exactly match ordinary states of *A. candidum.*

9. **HERPOLIRION** Hook. f.

A dwarf perennial herb. Rhizome slender, creeping, branched. Leaves crowded on short shoots from the rhizome, all radical, linear, distichous, sheathing at the base. Flower solitary, terminal, almost sessile amongst the leaves. Perianth funnel-shaped, persistent, 6-partite; segments distinct, linear, subequal, 5-nerved. Stamens 6, attached to the base of the segments and shorter than them; filaments filiform; anthers linear, erect, twisted after flowering, cells introrse, longitudinally dehiscent. Ovary subglobose, sessile, 3-celled; ovules several in each cell; style filiform; stigma terminal, punctiform. Capsule globose, enclosed in the persistent perianth, 3-celled, loculicidally 3-valved. Seeds oblong, subcompressed, quite smooth; testa black, crustaceous.

A monotypic genus confined to the mountains of New Zealand, Tasmania, and south-eastern Australia.

1. **H. novae-zealandiae** *Hook. f. Fl. Nov. Zel.* i (1853) 258.—Small, often forming broad patches in subalpine swamps. Leaves crowded, flat or involute, linear, striate, glaucous; the outer spreading or recurved, 1–2½ in. long; the inner much shorter, reduced to erect lanceolate sheathing bracts. Flower almost sessile, large for the size of the plant, ½–¾ in. long, lilac-blue or white. Perianth-segments erect below, spreading from a little below the middle. Stamens about ½ as long as the segments; filaments flattened, pubescent; anthers shortly sagittate at the base. Capsule globose-trigonous, ¼–⅓ in. diam.—*Handb. N.Z. Fl.* (1864) 287; *Cheesem. Man. N.Z. Fl.* (1906) 720. H. Tasmaniae *Hook. f. Fl. Tasm.* ii (1860) 54, t. 132B.

North Island: Kaikuri, Waitomo Caves, *E. Phillips Turner!* plains near Taupo, *Colenso! Tryon!* near Tongariro, *H. Hill! T. F. C.;* Whakaki, Hawke's Bay, *Bishop Williams!* Ruahine and Kaimanawa Mountains, *B. C. Aston!* South Island, Stewart Island: Not uncommon in subalpine swamps throughout. Usually from 2000 to 4000 ft., but descends to sea-level in Otago and Stewart Island. December–January.

10. **IPHIGENIA** Kunth.

Small glabrous herbs. Bulb tunicated. Stem simple, erect. Leaves few, scattered, linear, sheathing the stem. Flowers small, erect, solitary or corymbose. Perianth 6-partite, deciduous; segments free, all similar, linear or linear-oblong, spreading, flat. Stamens 6, hypogynous, shorter than the perianth; filaments flat; anthers oblong, versatile. Ovary superior, sessile, 3-celled; ovules numerous in each cell; styles 3, shortly connate at the base, linear, recurved, stigmatic along the inner edge. Capsule ovoid or oblong, 3–6-sulcate, 3-celled, loculicidally dehiscent. Seeds small, globose; testa thin, brown, appressed.

Besides the New Zealand species, which is endemic, there are 2 from India, 1 of which is also found in Australia, and 1 each from tropical Africa and Madagascar.

1. **I. novae-zealandiae** *Bak. in Journ. Linn. Soc.* xvii (1879) 451.—Bulb (corm) subglobose, ⅓ in. diam.; sheaths reddish, membranous. Stem 1–2 in. high. Leaves 2 or rarely 3, ½–3 in. long, narrow-linear, sheathing the greater part of the stem and exceeding it. Flower solitary, ¼ in. diam. Perianth-segments 4–6, oblanceolate, acute, with 6–8 longitudinal veins. Stamens 4–6, slightly shorter than the segments; anthers white, subglobose. Ovary broadly oblong, 2–3-celled; styles 2, rarely 3, subulate.

Capsule broadly oblong, usually 2-celled, $\frac{1}{6}$–$\frac{1}{5}$ in. diam.—*Cheesem. Man. N.Z. Fl.* (1906) 721. Anguillaria novae-zelandiae *Hook. f. ex T. Kirk in Trans. N.Z. Inst.* x (1878) App. xi.

South Island: Canterbury—*Lyall;* swamps near Christchurch, *J. B. Armstrong!* near Burnham, *T. Kirk!* Banks Peninsula, *Cockayne!* Lake Grassmere, *J. D. Enys!* Cass River, *Cockayne* and *Fowerake r!* Rangitata Valley, *Haast!* Otago—Otepopo, *Petrie!* Sea-level to 2500 ft. November–December.

Family XX. AMARYLLIDACEAE.

Usually perennial herbs, sometimes of large size. Rootstock bulbous, tuberous, tufted or creeping. Leaves generally all radical, narrow, not usually equitant or distichous. Flowers regular or slightly irregular, hermaphrodite, in terminal umbels or racemes or panicles, rarely solitary; peduncles or scapes naked or bracteate. Perianth superior, petaloid, tube long or short, limb 6-lobed or -partite, sometimes bearing at the throat a petaloid corona (*Narcissus*, &c.). Stamens 6, inserted on the perianth-tube or at the base of the segments and opposite to them; filaments free or united at the base; anthers 2-celled, versatile, introrse. Ovary inferior, 3-celled; style filiform or columnar, stigma simple or 3-fid; ovules numerous, in 2 series in the inner angle of each cell, anatropous. Fruit usually a 3-celled capsule with loculicidal dehiscence, rarely an indehiscent berry. Seeds generally numerous, sometimes reduced to 1 or 2 in each cell; albumen fleshy; embryo small, axile.

A well-known and widely distributed family, found in all warm and temperate countries, but (like the preceding family) decidedly rare in Asia. Genera 65; species under 700. It includes the American aloe (*Agave americana*), which can be applied to a wonderful variety of uses. Both it and other species of *Agave* are valuable fibre-plants, *A. rigida* being the well-known sisal hemp. The ornamental species are very numerous, the principal genera being *Narcissus, Galanthos* (snowdrop), *Leucoium* (snowflake), *Hippeastrum, Amaryllis, Vallota, Crinum, Alstraemeria, Agave, Fourcroya.* The single genus found in New Zealand is widely diffused.

1. HYPOXIS Linn.

Small herbs. Rhizome bulbous or tuberous, coated with a membranous or fibrous sheath. Leaves radical, narrow, flat or terete, often hairy. Scape 1- or many-flowered. Perianth regular, tube wanting; segments 6, nearly equal, spreading. Stamens 6, inserted on the base of the segments and shorter than them; anthers erect, linear or oblong, dorsifixed. Ovary inferior, 3-celled; ovules numerous in each cell, 2-seriate; style short, columnar; stigmas 3, stout, erect, distinct or connate. Capsule globose or oblong, membranous, 3-valved or circumscissile below the top. Seeds small, subglobose; testa crustaceous, shining, usually more or less beaked at the hilum.

Species over 50, mainly confined to southern or tropical Africa, a few only in Asia, Australasia, or America.

1. **H. pusilla** *Hook. f. Fl. Tasm.* ii (1860) 36, t. 130B.—Very small, 1–2 in. high. Rhizome globose, bulb-like, clothed with the setose remains of the old leaves, $\frac{1}{3}$ in. diam. Leaves 3–6, $\frac{1}{2}$–2 in. long, filiform, wiry,

flexuous, grooved down the inner face, base widened into a scarious sheath. Scapes shorter than the leaves, 1-3-flowered. Flowers small, $\frac{1}{6}$ in. diam. Perianth-segments ovate-lanceolate, acute. Stamens short, not $\frac{1}{2}$ as long as the perianth-segments; anthers linear, basified. Stigmas lanceolate, free. Capsule globose, $\frac{1}{8}$ in. diam.—*Handb. N.Z. Fl.* (1864) 275; *Benth. Fl. Austral.* vi (1873) 449; *Cheesem. Man. N.Z. Fl.* (1906) 701. H. hygrometrica *Hook. f. Fl. Nov. Zel.* i (1853) 253 (*not of R. Br.*).

North Island: Hawke's Bay—*Colenso.* South Island: Marlborough—Sandy ground near the mouth of the Wairau River, *J. H. Macmahon!* Canterbury—Banks Peninsula, *H. H. Travers, J. B. Armstrong! Cockayne!* Canterbury Plains, *J. B. Armstrong!* November–April.

Probably not uncommon on the eastern side of the South Island, but very easily overlooked. Also a native of Victoria and Tasmania.

Family XXI. **IRIDACEAE.**

Perennial herbs, with a tuberous or bulbous or creeping rhizome. Leaves usually all radical, narrow, equitant and distichous. Flowers hermaphrodite, regular or obliquely irregular, solitary and terminal, or in spikes or corymbs or panicles, or clustered, enclosed within 2 spathaceous usually scarious bracts. Perianth superior, petaloid, marcescent; segments 6, in 2 series, imbricate. Stamens 3, epigynous or inserted on the outer perianth-segments; filaments free or united into a tube; anthers 2-celled, opening outwards. Ovary inferior, 3-celled; style filiform, usually 3-fid above; divisions stigmatic at the end, subulate or narrow or broad, sometimes petaloid; ovules numerous, in the inner angle of each cell, anatropous. Fruit a coriaceous 3-celled usually trigonous capsule, loculicidally 3-valved. Seeds usually numerous, albuminous; embryo short, cylindric.

A large family, comprising nearly 60 genera and about 800 species, dispersed over the whole world, but most abundant and varied in South Africa, plentiful in south Europe, not infrequent in America, comparatively rare in Asia. The family includes few useful species. Some are said to be purgative and diuretic, and the dried stigmas of the saffron (*Crocus sativus*) are a well-known dye. Many of the species are cultivated in gardens on account of the beauty of their flowers, especially of the genera *Iris, Crocus, Ixia,* and *Gladiolus.* The single New Zealand genus extends to Australia on the one side and South America on the other.

LIBERTIA Spreng. 1825. Syst. 1: 127; 145.

Perennial herbs with a short creeping rhizome and long fibrous roots. Leaves numerous, densely crowded at the base of the stem, distichously imbricate, equitant, linear or ensiform, flat, rigid. Flowering-stems erect, simple or branched; cauline leaves few. Flowers on slender pedicels, clustered in the axils of sheathing bracts, forming a corymbose-paniculate or subumbellate inflorescence. Perianth regular, tube wanting; segments 6, spreading, free to the base, the 3 inner rather longer and broader. Stamens 3; filaments free or slightly connate at the base; anthers linear-sagittate, versatile. Ovary 3-celled; ovules many in each cell; style short, with 3 linear-subulate spreading branches. Capsule broadly oblong or obovoid or globose, 3-valved. Seeds angled or compressed, smooth or foveolate.

A small genus of 8 or 10 species, found in New Zealand, Australia, and extra-tropical South America. One of the New Zealand species extends to Australia and Tasmania, the remaining two are endemic.

Leaves $\frac{1}{6}$–$\frac{1}{3}$ in. broad. Flower-clusters many, panicled. Capsule $\frac{1}{3}$–$\frac{1}{2}$ in. long	1. *L. ixioides.*
Leaves $\frac{1}{3}$–$\frac{1}{2}$ in. Flower-clusters many, panicled. Capsule $\frac{1}{2}$–$\frac{3}{4}$ in. long	2. *L. grandiflora.*
Leaves $\frac{1}{12}$–$\frac{1}{6}$ in. Flower-clusters solitary or rarely 2–3. Capsule globose, $\frac{1}{5}$ in. diam.	3. *L. pulchella.*

1. **L. ixioides** *Spreng. Syst.* i (1825) 168.—Rhizome very short. Leaves numerous, densely tufted, 1–2 ft. long, $\frac{1}{6}$–$\frac{1}{3}$ in. broad, narrow-linear, acuminate, rigid and coriaceous, striate; margins cartilaginous, smooth or very obscurely and minutely scabrid. Flowering stem longer or shorter than the leaves, usually with 1 or 2 cauline leaves below the inflorescence. Panicle broad; branches alternate from the axils of membranous sheathing bracts, bearing subumbellate clusters of 2–10 rather large white flowers on long pedicels. Perianth variable in size, $\frac{1}{2}$–1 in. diam.; the 3 outer segments oblong or elliptic, often greenish on the outside; the 3 inner larger and broader, broadly oblong or orbicular, pure-white. Capsule broadly oblong or obovoid, $\frac{1}{3}$–$\frac{1}{2}$ in. long.—*A. Cunn. Precur.* (1836) n. 307; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 252; *Handb. N.Z. Fl.* (1864) 274; *Cheesem. Man. N.Z. Fl.* (1906) 699. L. restioides *Klatt in Linnaea,* xxxi (1861–62) 383. L. orbicularis *Col. in Trans. N.Z. Inst.* xv (1883) 329. Sisyrinchium ixioides *Forst. f. Prodr.* (1786) n. 325; *A. Rich. Fl. Nouv. Zel.* (1832) 161. Ferraria ixioides *Willd. Sp. Plant.* iii (1800) 582. Renealmia ixioides *Ker-Gawl Gen. Irid.* (1827) 27. Nematostigma ixioides *A. Dietr. Sp. Plant.* ii (1833) 27.

Var. *a.*—Bracts all lanceolate.

Var. *b.*—Upper bracts ovate, acute.

North and South Islands, Stewart Island, Chatham Islands: Abundant from the North Cape southwards. Sea-level to 2000 ft. *Tukauki.* October–December.

A very variable plant. Var. *b* appears to be rare in the North Island.

2. **L. grandiflora** *Sweet Hort. Brit.* ed. ii (1830) 498.—Habit of *L. ixioides,* but taller and stouter, 2–3 ft. high, with leaves $\frac{1}{3}$–$\frac{1}{2}$ in. broad. Flowering stem and bracts much as in *L. ixioides.* Flowers rather larger, the inner perianth-segments much larger and broader than the outer, often 3 or 4 times as large. Capsule much larger, $\frac{1}{2}$–$\frac{3}{4}$ in. long, broadly oblong or obovoid, yellow when fully ripe.—*Hook. f. Handb. N.Z. Fl.* (1864) 274; *Cheesem. Man. N.Z. Fl.* (1906) 699. L. macrocarpa *Klatt in Linnaea,* xxxi (1861–62) 384. Renealmia grandiflora *R. Br. Prodr.* (1810) Add. 592.

North and South Islands: From the North Cape to Otago, but not so common as *L. ixioides.* October–November.

But for the great difference in the size of the capsule this might very well have been regarded as a variety of *L. ixioides.*

3. **L. pulchella** *Spreng. Syst.* i (1825) 168.—Small, slender, 3–9 in. high. Rhizome often elongated, sometimes branched at the top. Leaves 2–6 in. long, $\frac{1}{12}$–$\frac{1}{6}$ in. broad, grassy, hardly rigid, margins smooth or ciliolate. Scape usually longer than the leaves, bearing a single terminal subumbellate cluster of 3–8 small white flowers, or in large specimens 1 or 2 other clusters

new species.

Libertia peregrinans, Ckn. & Allan.

North and South Is, and Chatham Is., forming extensive colonies in sand hollows.

"distinguished from L. ixioides by the far spreading rhizomes, emitting dense tufts of leaves at intervals."

see T.N.Z.I. vol. 57, p. 56. Ckn. & Allan.

Family XXII. BURMANNIACEAE.

Annual or perennial herbs, usually of small size and saprophytic; stems whitish or pink, rarely green; leaves usually absent. Flowers hermaphrodite, solitary and terminal or arranged in a 2-fid helicoid cyme. Perianth superior, regular, petaloid; segments 6 or 3, free. Stamens generally 6, affixed to the base of the perianth-tube; filaments short; anthers 2-celled, their connectives usually dilated, and sometimes connate into a tube. Ovary inferior, 1-celled with 3 parietal placentas, or 3-celled with as many axile placentas. Ovules numerous on each placenta, minute; style short, simple; stigmas 3. Fruit a capsule with variable dehiscence; seeds numerous, small.

A small family of about 16 genera and 75 species, almost confined to the tropics; but a few species extend into the North Temperate Zone, one reaching as far north as Illinois, in the United States. In the Southern Hemisphere a single species occurs in Tasmania and another in New Zealand. The species have no important properties or uses.

1. BAGNISIA Becc.

Small fleshy saprophytes, everywhere smooth and glabrous, leaves absent or reduced to scales. Rhizome creeping, sparingly or copiously branched, putting up here and there short erect peduncles or stems, furnished with small scale-like leaves or bracts. Flowers solitary, terminal, variously coloured. Perianth-lobes 6, the 3 inner larger, dilated at the tip, and connivent into a kind of hood; the 3 inner somewhat smaller, free. Stamens 6, affixed to the throat of the perianth-tube, abruptly deflexed; connectives very large, connivent into a tube; anthers 2-celled. Style short; apex 3-fid, stigmatose. Fruit turbinate; seeds numerous, small.

A curious little genus of 7 or 8 species; all Malayan except one found in New Zealand, another in Tasmania, and a third in the northern United States of America.

1. **B. (Geomitra) Hillii** *Cheesem. in Kew Bulletin* (1908) 420.—A minute colourless saprophyte, perfectly smooth in all its parts, leaves wanting or reduced to minute scales. Rhizomes creeping amongst humus at the base of tall forest-trees, sparingly or copiously branched, 2–4 in. long, $\frac{1}{40}$–$\frac{1}{30}$ in. diam., fleshy, naked. Peduncles springing from the axils of minute fleshy bracts, 1-flowered, erect or curved, $\frac{1}{5}$–$\frac{1}{2}$ in. long; bracteoles 3–7, alternate, lanceolate or ovate-lanceolate, acute or acuminate, the upper gradually larger, $\frac{1}{40}$–$\frac{1}{8}$ in. long. Flowers solitary, terminal, large

the leaves, usually with 1 or 2 cauline leaves below the inflorescence. Panicle broad; branches alternate from the axils of membranous sheathing bracts, bearing subumbellate clusters of 2–10 rather large white flowers on long pedicels. Perianth variable in size, ½–1 in. diam.; the 3 outer segments oblong or elliptic, often greenish on the outside; the 3 inner larger and broader, broadly oblong or orbicular, pure-white. Capsule broadly oblong or obovoid, ⅓–½ in. long.—*A. Cunn. Precur.* (1836) n. 307; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 252; *Handb. N.Z. Fl.* (1864) 274; *Cheesem. Man. N.Z. Fl.* (1906) 699. L. restioides *Klatt in Linnaea*, xxxi (1861–62) 383. L. orbicularis *Col. in Trans. N.Z. Inst.* xv (1883) 329. Sisyrinchium ixioides *Forst. f. Prodr.* (1786) n. 325; *A. Rich. Fl. Nouv. Zel.* (1832) 161. Ferraria ixioides *Willd. Sp. Plant.* iii (1800) 582. Renealmia ixioides *Ker-Gawl Gen. Irid.* (1827) 27. Nematostigma ixioides *A. Dietr. Sp. Plant.* ii (1833) 27.

Var. *a*.—Bracts all lanceolate.

Var. *b*.—Upper bracts ovate, acute.

North and South Islands, Stewart Island, Chatham Islands: Abundant from the North Cape southwards. Sea-level to 2000 ft. *Tukauki.* October–December.

A very variable plant. Var. *b* appears to be rare in the North Island.

2. **L. grandiflora** *Sweet Hort. Brit.* ed. ii (1830) 498.—Habit of *L. ixioides*, but taller and stouter, 2–3 ft. high, with leaves ⅓–½ in. broad. Flowering stem and bracts much as in *L. ixioides*. Flowers rather larger, the inner perianth-segments much larger and broader than the outer, often 3 or 4 times as large. Capsule much larger, ½–¾ in. long, broadly oblong or obovoid, yellow when fully ripe.—*Hook. f. Handb. N.Z. Fl.* (1864) 274; *Cheesem. Man. N.Z. Fl.* (1906) 699. L. macrocarpa *Klatt in Linnaea*, xxxi (1861–62) 384. Renealmia grandiflora *R. Br. Prodr.* (1810) Add. 592.

North and South Islands: From the North Cape to Otago, but not so common as *L. ixioides*. October–November.

But for the great difference in the size of the capsule this might very well have been regarded as a variety of *L. ixioides*.

3. **L. pulchella** *Spreng. Syst.* i (1825) 168.—Small, slender, 3–9 in. high. Rhizome often elongated, sometimes branched at the top. Leaves 2–6 in. long, $\frac{1}{12}$–$\frac{1}{6}$ in. broad, grassy, hardly rigid, margins smooth or ciliolate. Scape usually longer than the leaves, bearing a single terminal subumbellate cluster of 3–8 small white flowers, or in large specimens 1 or 2 other clusters

may be developed lower down the scape; pedicels very slender, pubescent, $\frac{3}{4}$–1 in. long; bracts numerous, whorled at the base of the clusters. Perianth $\frac{1}{3}$–$\frac{1}{2}$ in. diam.; segments almost equal, oblong-obovate. Capsule $\frac{1}{6}$–$\frac{1}{5}$ in. diam., globose, membranous.—*Benth. Fl. Austral.* vi (1873) 413; *Cheesem. Man. N.Z. Fl.* (1906) 700. L. micrantha *A. Cunn. Precur.* (1836) n. 308; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 252; *Handb. N.Z. Fl.* (1864) 274.

North and South Islands, Stewart Island: Damp mossy places in hilly forests throughout, not uncommon. Sea-level to 4000 ft. November–January. Also in south-eastern Australia and Tasmania.

Family XXII. BURMANNIACEAE.

Annual or perennial herbs, usually of small size and saprophytic; stems whitish or pink, rarely green; leaves usually absent. Flowers hermaphrodite, solitary and terminal or arranged in a 2-fid helicoid cyme. Perianth superior, regular, petaloid; segments 6 or 3, free. Stamens generally 6, affixed to the base of the perianth-tube; filaments short; anthers 2-celled, their connectives usually dilated, and sometimes connate into a tube. Ovary inferior, 1-celled with 3 parietal placentas, or 3-celled with as many axile placentas. Ovules numerous on each placenta, minute; style short, simple; stigmas 3. Fruit a capsule with variable dehiscence; seeds numerous, small.

A small family of about 16 genera and 75 species, almost confined to the tropics; but a few species extend into the North Temperate Zone, one reaching as far north as Illinois, in the United States. In the Southern Hemisphere a single species occurs in Tasmania and another in New Zealand. The species have no important properties or uses.

1. BAGNISIA Becc.

Small fleshy saprophytes, everywhere smooth and glabrous, leaves absent or reduced to scales. Rhizome creeping, sparingly or copiously branched, putting up here and there short erect peduncles or stems, furnished with small scale-like leaves or bracts. Flowers solitary, terminal, variously coloured. Perianth-lobes 6, the 3 inner larger, dilated at the tip, and connivent into a kind of hood; the 3 inner somewhat smaller, free. Stamens 6, affixed to the throat of the perianth-tube, abruptly deflexed; connectives very large, connivent into a tube; anthers 2-celled. Style short; apex 3-fid, stigmatose. Fruit turbinate; seeds numerous, small.

A curious little genus of 7 or 8 species; all Malayan except one found in New Zealand, another in Tasmania, and a third in the northern United States of America.

1. **B.** (**Geomitra**) **Hillii** *Cheesem. in Kew Bulletin* (1908) 420.—A minute colourless saprophyte, perfectly smooth in all its parts, leaves wanting or reduced to minute scales. Rhizomes creeping amongst humus at the base of tall forest-trees, sparingly or copiously branched, 2–4 in. long, $\frac{1}{40}$–$\frac{1}{30}$ in. diam., fleshy, naked. Peduncles springing from the axils of minute fleshy bracts, 1-flowered, erect or curved, $\frac{1}{5}$–$\frac{1}{2}$ in. long; bracteoles 3–7, alternate, lanceolate or ovate-lanceolate, acute or acuminate, the upper gradually larger, $\frac{1}{40}$–$\frac{1}{8}$ in. long. Flowers solitary, terminal, large

for the size of the plant, ¼–½ in. long, about ⅕ in. broad, bright rose-pink when fresh. Perianth campanulate-lanterniform; tube obovate-oblong, distinctly 6–12-costate; outer perianth-segments smaller, free, linear or oblong, at first erect but ultimately spreading, sometimes abruptly recurved. Inner segments almost twice the length of the outer, linear-spathulate to obovate-oblong, connate or connivent at the tip, gaping at the middle, keeled on the back, with the keel produced upwards into a subulate point. Stamens 6, affixed to the throat of the perianth-tube, shortly exserted, abruptly deflexed within the tube; filaments very short, free; anther-connectives much enlarged and expanded, connate into a membranous tube which is bilamellate at the apex; anther-cells small, distinct, placed towards the base of the tube formed by the connectives. Ovary inferior, broadly obovoid, 1-celled; placentas 3, free; ovules very numerous; style short, thick; stigma 3-lobed, the lobes broad, almost quadrate, concave, truncate at the tip. Fruit unknown.—*Cheesem. Illus. N.Z. Fl.* ii (1914) t. 191A. Thismia Hillii *Pfeiffer in Bot. Gazette*, lvii (1914) 122.

North Island: Forests at Opepe, near Lake Taupo, on mounds of humus at the base of *Podocarpus dacrydioides* and other trees, alt. 2000 ft., *H. Hill! A. Hamilton! T. F. C.* January. WLH? Cunn, ad Tangarino.

A very remarkable little plant. It is closely allied to the Tasmanian *B. Rodwayi*, but a comparison between Mr. Rodway's plate given in his "Tasmanian Flora" and Miss Smith's careful drawing of *B. Hillii* in my "Illustrations of the New Zealand Flora" (t. 191) will show structural differences of considerable importance.

Miss Pfeiffer, in a valuable paper printed in the *Botanical Gazette* (vol. xlvii, p. 122), suggests that *Bagnisia*, with several allied genera, should be merged with *Thismia*. This step appears to me to be retrograde, and not at all in keeping with the work done of late years in the family by Warming, Urban, and Engler.

Roxb. Proc. Linn. Soc. N.S.W. 53: 1928. 556.

Family XXIII. **ORCHIDACEAE.**

Herbs, either terrestrial and tuberous-rooted, with annual herbaceous stems, or epiphytes with creeping rhizomes emitting fibrous or fleshy roots and bearing simple or branched leafy stems often thickened into pseudobulbs. Flowers hermaphrodite, solitary or in spikes or racemes or panicles, often large and showy. Perianth superior, irregular, of 6 free or more or less combined segments, in 2 series; the 3 outer (sepals) all similar or the dorsal one larger and more concave than the 2 lateral which are always alike; the 3 inner (petals) always dissimilar (except in *Thelymitra*), the 2 lateral alike, but the third (called the lip, or *labellum*) usually exceedingly different, often spurred, lobed, fringed, or furnished with glands or other appendages. Stamens and style confluent into a fleshy variously shaped central body facing the lip, called the column; anther usually solitary (2 in *Cypripedium*), placed on the front, top, or back of the column, and either free or adnate to it, persistent or deciduous, usually 2-celled; pollen granular or waxy, usually cohering in each cell into 1, 2, or 4 pairs of pollen-masses (*pollinia*), which are either free or attached, directly or by a caudicle, to a gland on the apex of the stigma (*rostellum*). Ovary inferior, 1-celled; ovules numerous, on 3 parietal placentas; stigma a viscid depression towards the top or on the front of the column, below the anther, facing the lip, upper margin often produced into a beak or point called the rostellum. Fruit a 1-celled 3-valved capsule; seeds numerous, very minute; testa loose, reticulate; albumen wanting; embryo solid, fleshy.

A very extensive and distinct family, found in almost all parts of the world, but rare or absent in extreme northern or southern latitudes, and on the tops of high alpine mountains. Most of the species found in temperate countries are terrestrial; but in the tropics the greater number are epiphytes, growing upon the branches or trunks of trees

Roxb. Proc. Linn. Soc. N.S.W. 53: 1928. 556.

Family XXIII. **ORCHIDACEAE.**

Herbs, either terrestrial and tuberous-rooted, with annual herbaceous stems, or epiphytes with creeping rhizomes emitting fibrous or fleshy roots and bearing simple or branched leafy stems often thickened into pseudobulbs. Flowers hermaphrodite, solitary or in spikes or racemes or panicles, often large and showy. Perianth superior, irregular, of 6 free or more or less combined segments, in 2 series; the 3 outer (sepals) all similar or the dorsal one larger and more concave than the 2 lateral which are always alike; the 3 inner (petals) always dissimilar (except in *Thelymitra*), the 2 lateral alike, but the third (called the lip, or *labellum*) usually exceedingly different, often spurred, lobed, fringed, or furnished with glands or other appendages. Stamens and style confluent into a fleshy variously shaped central body facing the lip, called the column; anther usually solitary (2 in *Cypripedium*), placed on the front, top, or back of the column, and either free or adnate to it, persistent or deciduous, usually 2-celled; pollen granular or waxy, usually cohering in each cell into 1, 2, or 4 pairs of pollen-masses (*pollinia*), which are either free or attached, directly or by a caudicle, to a gland on the apex of the stigma (*rostellum*). Ovary inferior, 1-celled; ovules numerous, on 3 parietal placentas; stigma a viscid depression towards the top or on the front of the column, below the anther, facing the lip, upper margin often produced into a beak or point called the rostellum. Fruit a 1-celled 3-valved capsule; seeds numerous, very minute; testa loose, reticulate; albumen wanting; embryo solid, fleshy.

A very extensive and distinct family, found in almost all parts of the world, but rare or absent in extreme northern or southern latitudes, and on the tops of high alpine mountains. Most of the species found in temperate countries are terrestrial; but in the tropics the greater number are epiphytes, growing upon the branches or trunks of trees or on rocks. The genera are estimated at 425, the species between 5500 or 6000. Notwithstanding the great extent of the family, it is singularly deficient in useful plants. The only one possessing any commercial importance is vanilla, the scented pods of which are used for flavouring delicate dishes or liqueurs. The great beauty and singularity of the flowers of many of the tropical species have caused them to be extensively cultivated in hothouses, and probably over 2000 distinct species are now grown by European horticulturists.

The close affinity existing between the flora of New Zealand and that of Australia is nowhere better shown than in the *Orchideae*. Out of 21 genera found in New Zealand, 20 occur in Australia as well, and 8 are absolutely confined to the two countries, while several others have a very limited additional range. The only genera with a wide distribution are *Dendrobium*, *Bulbophyllum*, and *Spiranthes*. *Earina*, which does not occur in Australia, is found in the Pacific islands.

A. Epiphytes with creeping rhizomes, perennial stems, and evergreen leaves. Pollinia waxy, free or attached by caudicles to the rostellum.

* Pollinia free.

The New Zealand species with slender much-branched stems, no pseudobulbs, and axillary flowers. Lateral sepals and lip adnate to the base of the column .. .. 1. DENDROBIUM.

The New Zealand species forming small matted patches on the trunks of trees, furnished with pseudobulbs. Flowers on a scape rising from the base of the pseudobulb. Lip jointed on to the base of the column, mobile .. .. 2. BULBOPHYLLUM.

Stems leafy, unbranched. Flowers in terminal panicles. Lateral sepals free. Lip 3-lobed .. .. 3. EARINA.

** Pollinia attached to the rostellum by a caudicle.

Stems short, leaves few. Flowers small, in lateral racemes. Lip 3-lobed .. .. 4. SARCOCHILUS.

B. Terrestrial, with tuberous roots and annual stems. Pollinia granular or powdery.

* Leaves long, very narrow-linear, flat or terete.

a. Leaves more than one.

Flowers numerous, on a spirally twisted spike. Dorsal sepal and petals connivent into a hood. Lip undivided .. .. 5. SPIRANTHES.

Flowers several, spicate. Dorsal sepal broad, hooded; lateral linear or filiform, erect. Lip 3-lobed .. .. .. 7. ORTHOCERAS.

b. Leaf solitary.

Sepals, petals, and lip all similar in shape, petaloid. Column very short, not attached to the lip at the base .. .. .. 6. THELYMITRA.

Dorsal sepal concave. Petals much smaller. Surface of lip covered with long hairs. Column very short .. .. .. 14. CALOCHILUS.

Dorsal sepal concave. Lip uppermost, undivided, usually with an adnate gland on the disc. Column very short, with two lateral erect appendages .. .. 9. PRASOPHYLLUM.

Dorsal sepal concave. Lip below, entire or 2-lobed. Column very short .. .. 8. MICROTIS.

Sepals and petals all linear. Lip uppermost, articulate, clawed; lamina peltate, irritable and mobile. Column long, winged .. 10. CALEANA.

Sepals and petals narrow. Lip entire or 3-lobed, not jointed or irritable, disc with glandular processes, margin often fringed. Column long, winged above .. .. 16. CALADENIA.

** Leaves shorter, two or several, oblong or lanceolate or linear.

Leaves numerous; radical broad, sometimes wanting; cauline narrow. Flowers hood-shaped, green. Lateral sepals united at the base. Lip narrow, irritable, with a basal appendage .. 11. PTEROSTYLIS.

Leaves 2–3, lanceolate. Upper sepal broad, concave; lateral narrow. Lip broad, papillose or ridged. Column not winged .. 15. LYPERANTHUS.
Leaves 2, radical, oblong. Upper sepal broad, concave; lateral narrow-linear. Lip broad, with raised glands on the disc. Column winged, wings produced into 2 erect lobes at the top .. 17. CHILOGLOTTIS.

*** Leaf solitary, broad.

Flower solitary, large, purple. Upper sepal broad, concave; lateral and petals long and filiform or minute. Lip large, broad, involute. Column very short .. .. 20. CORYSANTHES.
Flower solitary. Upper sepal narrow, concave; lateral and petals lanceolate. Lip 3-lobed; disc with raised glands. Column long, winged above; wing produced upwards into 2 toothed lobes .. 18. ADENOCHILUS.
Flowers 1 or 2. Upper sepal broad, concave; lateral lanceolate. Petals minute. Lip broad, undivided; disc smooth. Column long, equally winged, wings not produced upwards .. .. 19. TOWNSONIA.
Flowers several. Sepals and petals narrow, acuminate. Lip spreading, broad, concave. Column long .. .. .. 12. ACIANTHUS.
Flowers 2–3. Sepals and petals linear, obtuse. Lip spreading, narrow, flat. Column long, winged above .. .. .. 13. CYRTOSTYLIS.

**** Leafless. Stem tall, with brown sheathing scales.

Sepals and petals united into a 5-lobed ventricose tube .. .. 21. GASTRODIA.

The above clavis is purely artificial, and is solely intended to facilitate the determination of the genera. The following arrangement, which is adapted from Hooker and Bentham's "Genera Plantarum" and Engler's "Pflanzenfamilien," is more natural and shows the sequence adopted in this work:—

Tribe I. EPIDENDREAE.—Anther lid-like, usually deciduous; cells parallel, distinct. Pollinia waxy, 1–4 in each cell, free, or those of each cell connected by a viscid appendage, not attached by their bases or by a caudicle to the rostellum.

1. DENDROBIUM. 2. BULBOPHYLLUM. 3. EARINA.

Tribe II. VANDEAE.—Anther lid-like, usually deciduous, resting on the rostellum; cells usually confluent. Pollinia waxy, usually 2 or 4 in superposed pairs, attached singly or in pairs to a gland or process of the rostellum, which comes away with them when they are removed.

4. SARCOCHILUS.

Tribe III. NEOTTIEAE.—Anther lid-like or erect and persistent; cells distinct, parallel. Pollinia granular or powdery.

Subtribe 1. *Spirantheae.*

5. SPIRANTHES.

Subtribe 2. *Thelymitreae.*

6. THELYMITRA.

Subtribe 3. *Diurideae.*

7. ORTHOCERAS. 8. MICROTIS. 9. PRASOPHYLLUM.

Subtribe 4. *Pterostylideae.*

10. CALEANA. 11. PTEROSTYLIS.

Subtribe 5. *Caladeniae.*

12. ACIANTHUS. 13. CYRTOSTYLIS. 14. CALOCHILUS. 15. LYPERANTHUS. 16 CALADENIA. 17. CHILOGLOTTIS. 18. ADENOCHILUS. 19. TOWNSONIA.

Subtribe 6. *Pogonieae.*

20. CORYSANTHES.

Subtribe 7. *Gastrodieae.*

21. GASTRODIA.

1. **DENDROBIUM** Swartz.

Epiphytes. Stems long and branching, or short and simple and thick, sometimes reduced to pseudobulbs. Leaves coriaceous or fleshy, never plaited. Flowers often large and handsome, rarely small. Sepals nearly equal, the lateral ones dilated at the base, and obliquely adnate to the foot of the column, forming a short spur or pouch. Petals about as long as the upper sepal. Lip contracted at the base and adnate to the produced foot of the column, rarely clawed, usually 3-lobed; lateral lobes embracing the column or spreading; middle lobe broad or narrow, spreading or recurved; disc often lamellate. Column short, produced at the base, winged or angled or toothed at the top. Anther terminal, lid-like, 2-celled; pollinia 4, free, compressed, in collateral pairs in each cell.

A large genus of probably 600 species, most abundant in the Malay Archipelago, but extending as far north as Japan, and southwards through Australia and Polynesia to New Zealand. The single species found in New Zealand is endemic, but is closely allied to the Polynesian *D. biflorum* Swartz.

1. **D. Cunninghamii** *Lindl. Bot. Reg.* sub. t. 1756.—Stems usually much branched, slender, rigid, wiry, terete, polished, 1–4 ft. long; usually pendulous, but small specimens growing on rocks or in exposed places are often erect. Leaves numerous, distichous, alternate, $\frac{3}{4}$–2 in. long, $\frac{1}{6}$–$\frac{1}{5}$ in. broad, linear-lanceloate, acute, rigid and coriaceous, striate and more or less conspicuously 3-nerved; sheaths truncate, grooved and transversely corrugated. Peduncles shorter or longer than the leaves, usually 1–3-flowered, rarely 3–6-flowered; pedicels slender; bracts short. Flowers $\frac{3}{4}$ in. diam., white and pink. Upper sepal oblong-lanceolate, acute; lateral rather larger, broader at the base. Petals about equalling the sepals, oblong, obtuse. Lip attached by a short claw to the foot of the column, 3-lobed; lateral lobes small, ascending; middle lobe spreading, large, almost as broad as long; margins undulate; disc with 4 or 5 thin lamellae. Capsule oblong, $\frac{1}{3}$ in. long.—*A. Cunn. Precur.* (1836) n. 316; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 240; *Handb. N.Z. Fl.* (1864) 262; *Cheesem. Man. N.Z. Fl.* (1906) 663. D. biflorum *A. Rich. Fl. Nouv. Zel.* (1832) 167, t. 26 (*not of Swartz*). D. Lessonii *Col. in Trans. N.Z. Inst.* xv (1883) 326.

North and South Islands, Stewart Island: Lowland districts from the North Cape southwards, not uncommon in forests. Sea-level to 2000 ft. December–February.

For some notes on the fertilization, see a paper by Mr. G. M. Thomson in Trans. N.Z. Inst. xi (1879) 419. I cannot separate Mr. Colenso's *D. Lessonii* from the ordinary state of the plant, even as a variety.

2. **BULBOPHYLLUM** Thouars.

Epiphytes. Rhizome creeping, often matted, usually more or less clothed with scarious sheathing scales. Pseudobulbs sessile in the axils of the scales, each crowned with 1 or rarely 2 leaves. Flowers small or large, solitary, spiked or racemed on a peduncle arising from the base of the pseudobulbs. Sepals nearly equal, the lateral ones adnate to the foot of the column. Petals usually smaller than the sepals. Lip contracted at the base and jointed on to the produced foot of the column, usually small and recurved, generally mobile. Column short, erect, produced at the base, often 2-aristate at the top. Anther terminal, lid-like, 2-celled; pollinia 4 (rarely 2), free, in pairs in each cell.

A genus of over 275 species, with its chief centre of distribution in tropical Asia, but also found in tropical Africa, Australia, New Zealand, and sparingly in South America.

Leaves $\frac{1}{2}$–1 in. Peduncles 2–4-flowered. Lip orange-red .. 1. *B. tuberculatum.*

Leaves $\frac{1}{4}$–$\frac{1}{3}$ in. Flowers solitary. Lip white .. .. .. 2. *B. pygmaeum.*

1. **B. tuberculatum** *Col. in Trans. N.Z. Inst.* xvi (1884) 336, *and* xxii (1890) 488.—Forming densely matted patches on the trunks or branches of trees. Pseudobulbs $\frac{1}{4}$–$\frac{1}{3}$ in. long, broadly oblong or nearly orbicular, almost smooth and unwrinkled when fresh, deeply rugose when dry, more or less clothed with white bullate scales. Leaves solitary on the pseudobulbs, $\frac{1}{2}$–1 in. long, linear-oblong, acute at both ends, thick and fleshy, slightly concave above, midrib prominent beneath, striate, under-surface with minute whitish dots. Peduncles very slender, almost filiform, $\frac{1}{2}$–$\frac{3}{4}$ in. long, 2–4-flowered; pedicels short; bracts minute. Flowers $\frac{1}{6}$ in. long, white with a bright reddish-orange lip. Upper sepal oblong-lanceolate, subacute; lateral larger, triangular, broad at the base. Petals triangular, much smaller than the sepals. Lip almost as long as the sepals, hinged on to the produced base of the column; lamina oblong-ovate or subhastate, truncate at the base, concave, very thick and fleshy, lower part of disc with 2 minute raised ridges. Column very short, stout, 2-winged at the top. Capsule broadly oblong, $\frac{1}{6}$ in. long.—*Cheesem. Man. N.Z. Fl.* (1906) 664; *Ill. N.Z. Fl.* ii (1914) t. 191. B. exiguum *Buch. in Trans. N.Z. Inst.* xvi (1884) 397 (*not of F. Muell.*).

North Island: Auckland—Kaitaia, *R. H. Matthews!* Lower Waikato, *H. Carse!* East Cape district, *T. Kirk.* Hawke's Bay—Petane, *A. Hamilton!* Wellington—Palmerston North, *A. Hamilton!* South Island: Nelson—Collingwood, *Dall!* April–May.

A charming little plant. It was referred by Mr. Buchanan to the Australian *B. exiguum*, and no doubt is closely allied to it, principally differing in the smaller size and more compact habit, shorter peduncles, shorter and broader sepals and petals, and broader and thicker bright orange-red lip.

2. **B. pygmaeum** *Lindl. Gen. et Sp. Orch.* (1830) 58.—Minute, forming densely matted carpets on the trunks of trees or on rocks. Pseudobulbs $\frac{1}{8}$–$\frac{1}{6}$ in. diam., globose or globose-depressed, glabrous, much wrinkled when dry. Leaves solitary on the pseudobulbs, springing from a minute circular sheath, $\frac{1}{4}$–$\frac{1}{3}$ in. long, linear-oblong, obtuse, very thick and coriaceous, grooved down the middle and minutely echinulate above, naked and longitudinally nerved beneath. Peduncles solitary from the base of the pseudobulbs, very short, $\frac{1}{3}$–$\frac{1}{6}$ in. long, 1-flowered; bract minute. Flowers very minute, whitish. Upper sepal narrow-ovate; lateral rather larger, broadly triangular. Petals shorter than the sepals, oblong, subacute. Lip clawed on to the projecting foot of the column; claw long; lamina ovate, obtuse, thickened, disc with indistinct ridges. Ovary broadly oblong, gibbous, minutely echinulate.—*A. Cunn. Precur.* (1836) n. 317; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 240; *Handb. N.Z. Fl.* (1864) 263; *Cheesem. Man. N.Z. Fl.* (1906) 664. B. ichthyostomum *Col. in Trans. N.Z. Inst.* xxvi (1894) 319. Dendrobium pygmaeum *Smith in Rees Cyclop.* xi (1802) n. 27.

North and South Islands: On the trunks of trees or rocks, from the North Cape to Otago; in the South Island chiefly on the western side. Sea-level to 1500 ft. November–February.

I do not see upon what grounds Mr. Colenso has separated his *B. ichthyostomum.* The type specimens in his herbarium appear to me to be typical *B. pygmaeum.*

3. **EARINA** Lindl.

Epiphytes. Stems tufted, simple, compressed; pseudobulbs wanting. Leaves distichous, alternate, narrow-linear. Flowers rather small, in terminal simple or branched bracteate racemiform panicles. Sepals about equal, spreading, free. Petals similar to the sepals. Lip affixed to the base of the column or its slightly produced foot, 3-lobed; lateral lobes small or large; middle lobe broad, entire or emarginate or 2-lobed. Column short, stout, sometimes produced at the base. Anther terminal, lid-like, 2-celled; pollinia 4, waxy, aggregated in pairs in each cell, free or cohering at the base by a short viscid appendage. Capsule oblong.

Besides the three species found in New Zealand, which are endemic, there are five or six species in the Pacific islands, ranging from New Caledonia to Tahiti.

Slender. Leaves $\frac{1}{6}$–$\frac{1}{5}$ in. broad. Flowers remote, $\frac{1}{4}$ in. diam. Lip deeply 3-lobed, disc eglandular .. .. 1. *E. mucronata.*
More rigid. Leaves $\frac{1}{5}$–$\frac{1}{3}$ in. broad. Flowers remote, $\frac{1}{3}$ in. diam. Lip deeply 3-lobed, lobes more acute, disc eglandular .. .. 2. *E. aestivalis.*
Stout, rigid. Panicle stiff, flowers close. Lip very obscurely 3-lobed, disc with 2 ridges .. .. 3. *E. autumnalis.*

1. **E. mucronata** *Lindl. in Bot. Reg.* (1835) sub. t. 1699.—Rhizome creeping. Stems numerous, 1–3 ft. long, slender, simple, pendulous or rarely erect, smooth, compressed and 2-edged, spotted. Leaves 3–6 in. long, $\frac{1}{6}$–$\frac{1}{5}$ in. broad, narrow-linear, acuminate, flat, smooth, thin but coriaceous, very finely striate. Panicle terminal, slender, sparingly branched, 2–5 in. long, many-flowered; bracts clasping, striate. Flowers rather distant, sessile, $\frac{1}{4}$ in. diam. Sepals and petals linear-oblong, spreading, obtuse, pale-yellow. Lip darker yellow with a brownish-orange spot at the base, deeply 3-lobed; middle lobe broader than long, again divaricately 2-lobed; disc eglandular. Column short, stout. Pollinia attached at the base to a short caudicle. Capsule oblong, $\frac{1}{4}$ in. long.—*A. Cunn. Precur.* (1836) n. 315; *Raoul Choix* (1846) 41; *Hook. Ic. Plant.* (1842) t. 431; *Hook. f. Fl. Nov. Zel.* i (1853) 239; *Handb. N.Z. Fl.* (1864) 262; *Cheesem. Man. N.Z. Fl.* (1906) 665. E. quadrilobata *Col. in Trans. N.Z. Inst.* xv (1883) 325.

North and South Islands, Stewart Island, Chatham Islands: Not uncommon in lowland forests throughout, epiphytic on the trunks and limbs of trees, more rarely on rocks. Sea-level to 2000 ft. October–December.

2. **E. aestivalis** *Cheesem. in Trans. N.Z. Inst.* li (1919) 93.—Rhizome creeping, much as in *E. mucronata.* Stems numerous, 9–18 in. long, suberect or drooping, smooth, compressed, rather broader and stouter than in *E. mucronata,* and firmer. Leaves 3–6 in. long, $\frac{1}{5}$–$\frac{1}{3}$ in. broad, flat, stiff, erect, narrow-linear, acute or acuminate; midrib and veins conspicuous on the under-surface, not so evident above. Panicle terminal, 2–5 in. long; branches or racemes 3–7, rarely more, 1–1$\frac{1}{2}$ in. long, 4–7-flowered; bracts short and broad, clasping, many-striate. Flowers larger than in *E. mucronata,* $\frac{1}{3}$ in. diam. or more. Sepals and petals similar in size and shape, linear-oblong, subacute. Lip longer than in *E. mucronata,* and brighter in colour; lateral lobes wider and more acute. Column short, stouter.

North Island: Mongonui County, in forest near Ahipara, *H. B. Matthews!* and at Kaiaka, *H. Carse!* In forest near Muriwai, and near the mouth of the Waitakere River, *T. F. C.* Forest by the Waikanae River, Wellington, *B. H. Morison!* Sea-level to 1500 ft. January–February.

Although only recently described, I have been acquainted with this for many years, having gathered specimens at Muriwai as far back as 1895. It is doubtless a close relative of *E. mucronata*, but is separated without much difficulty by the stiffer and more robust habit, shorter firmer and broader leaves, larger flowers, and longer labellum, the lateral lobes of which are longer and more acute.

3. **E. autumnalis** *Hook. f. Fl. Nov. Zel.* i (1853) 239.—Stems stout, erect or pendulous, slightly compressed, 6–18 in. high. Leaves 2–4 in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, narrow-linear or narrow linear-lanceolate, acute, rigid, coriaceous, striate, midrib evident. Panicle terminal, stiff, 2–4 in. long, many-flowered; branches numerous, close-set; bracts sheathing, striate. Flowers sessile, much closer together than in *E. mucronata*, $\frac{1}{4}$–$\frac{1}{3}$ in. diam., waxy-white with a yellow centre, very fragrant. Sepals ovate-oblong, obtuse. Petals rather broader, obovate, narrowed at the base. Lip erect at the base and then bent outwards, broad, concave, very obscurely 3-lobed, disc with 2 crescent-shaped glands towards the base, margins undulate. Column short, stout. Pollinia pyriform, attached to a short caudicle at the base.—*Handb. N.Z. Fl.* (1864) 262. E. suaveolens *Lindl. in Bot. Reg.* (1843) Misc. 61; *Cheesem. Man. N.Z. Fl.* (1906) 666. E. alba *Col. in Trans. N.Z. Inst.* xviii (1886) 267. Epidendrum autumnale *Forst. f. Prodr.* (1786) n. 319. Cymbidium autumnale *Swartz in Nov. Act. Upsal.* vi (1799) 72; *A. Rich. Fl. Nouv. Zel.* (1832) 169.

North and South Islands, Stewart Island: Not uncommon in lowland forests from the North Cape southwards. Sea-level to 2000 ft. March–June.

A handsome species, easily distinguished from *E. mucronata* by the shorter and stouter habit, more rigid leaves, denser panicles, waxy-white flowers, and almost entire lip, which has two raised ridges near the base. Mr. Colenso apparently published his *E. alba* under the supposition that *E. suaveolens* has no glands on the lip, but they are always present. Some notes on the fertilization are given by Mr. G. M. Thomson in the Trans. N.Z. Inst. xi (1879) 418.

4. SARCOCHILUS R. Br.

Epiphytes. Stems short, rarely long; pseudobulbs wanting. Leaves distichous, flat, oblong or linear, coriaceous or fleshy. Flowers racemose or spicate; peduncles lateral. Sepals spreading, almost equal, free; the lateral ones often broader at the base and adnate to the produced foot of the column. Petals similar to the sepals or narrower. Lip attached to the base of the column, usually 3-lobed; lateral lobes small or large, fleshy or petaloid; middle lobe often greatly reduced; disc usually with callosities. Column erect, semiterete, not winged, produced at the base. Anther terminal, lid-like, 2-celled; pollinia 2, or 4 more or less connate in pairs, waxy, attached by a strap-shaped caudicle to the rostellum. Capsule linear or linear-oblong.

A genus of about 35 species, most of them from India, the Malay Archipelago and Australia; a few from the Pacific islands, and one from New Zealand.

1. **S. adversus** *Hook. f. Fl. Nov. Zel.* i (1853) 241.—Roots numerous, long, wiry, terete. Stems short, 1–3 in. long, concealed by the imbricated sheathing bases of the leaves. Leaves few, distichous, spreading, 1–2$\frac{1}{2}$ in. long, $\frac{1}{3}$–$\frac{3}{4}$ in. broad, linear-oblong to elliptic-oblong, obtuse or subacute, jointed above the sheathing base, thick and coriaceous, dark-green, often spotted with purple. Peduncles 1–4 from the axils of the lower leaves, slender, strict, 1–2$\frac{1}{2}$ in. long, 5–15-flowered; pedicels slender, erect; bracts small, broadly ovate. Flowers small, $\frac{1}{8}$–$\frac{1}{6}$ in. diam., green spotted with

purple. Sepals oblong-ovate, obtuse. Petals similar but slightly narrower. Lip as broad as long, obscurely 3-lobed, very concave, with a fleshy gland on each side; tip obtuse, somewhat hooded. Column very short, stout. Capsule linear-oblong, $\frac{1}{2}$–$\frac{2}{3}$ in. long.—*Handb. N.Z. Fl.* (1864) 263; *Cheesem. Man. N.Z. Fl.* (1906) 667. S. breviscapa *Col. in Trans. N.Z. Inst.* xiv (1882) 332.

North and South Islands, Stewart Island, Chatham Islands: Not uncommon in lowland forests from the North Cape southwards, usually on the trunks of trees. October–November.

5. **SPIRANTHES** L. C. Rich.

Terrestrial herbs, with fibrous or tuberous roots. Stems leafy or sometimes leafless at the time of flowering. Flowers small, spirally arranged in a terminal spike. Sepals subequal; the dorsal one erect, more or less connivent with the petals into a hood; lateral free, erect or spreading. Lip sessile or clawed, concave, closely embracing the column at its broad base, often spreading and dilated at the tip; disc usually with tubercles or lamellae near the base. Column short, terete. Anther erect, ovate or oblong, 2-celled; pollinia after dehiscence pendulous from the gland of the rostellum.

A genus of nearly 100 species, generally dispersed through most temperate or tropical regions.

1. **S. australis** *Lindl. in Bot. Reg.* (1843) t. 823.—Root of several stout and fleshy almost tuberous fibres. Stem variable in size, 6–20 in. high, stout or slender, glabrous or nearly so below the inflorescence. Lower leaves varying from 2 to 6, 2–6 in. long, narrow-linear or linear-lanceolate, acuminate, sheathing at the base; upper ones reduced to sheathing scales. Spike slender, 2–6 in. long or more, spirally twisted, glandular-pubescent. Flowers numerous, small, sessile, close-set or rather distant, $\frac{1}{10}$–$\frac{1}{8}$ in. long, rose-pink or white; bracts ovate, acuminate, usually as long as the flowers. Upper sepal oblong, obtuse, connivent with the petals into a hood; lateral free, acute. Lip broadly oblong, concave; the lower part embracing the column and bearing a small rounded gland on each side at the base; upper part spreading and thickened; margins usually much crisped. Ovary glandular.—*Hook. f. Fl. Tasm.* ii (1860) 15; *Handb. N.Z. Fl.* (1864) 272; *Benth. Fl. Austral.* vi (1873) 314; *Cheesem. Man. N.Z. Fl.* (1906) 667. S. novae-zealandiae *Hook. f. Fl. Nov. Zel.* i (1853) 243.

North Island: Auckland—Near Ohora, *T. F. C.*; Waipapakauri and Rangaunu Harbour, *H. Carse!* Kaitaia, *R. H. Matthews!* Great Barrier Island, *T. Kirk*; near Auckland, *T. F. C.*; Waihi, *H. B. Devereux!* Upper Waikato, *Colenso*; Rotorua, *T. F. C.*; Waimarino Plains, *E. Phillips Turner!* Taranaki—Swamps near New Plymouth; Ngaire Swamp, *T. F. C.* South Island: Lake Ellesmere and New Brighton, *A. Wall*; Okarito, *A. Hamilton.* Sea-level to 1500 ft. January–February.

Also found in Australia, and in many parts of tropical and temperate Asia.

6. **THELYMITRA** Forst.

Terrestrial herbs, usually glabrous. Root of oblong or ovoid tubers. Leaf solitary, linear or lanceolate, often thick and fleshy but not terete; empty sheathing bracts 1 or 2 along the stem. Flowers few or many in a terminal raceme, sometimes reduced to one. Sepals and petals similar

and equal or nearly so, spreading. Lip similar to the petals, quite free from the column at the base. Column short, erect, broadly 2-winged; the wings either produced behind the anther with a variously lobed or fringed or rarely entire margin, or with 2 prominent lateral lobes as long or longer than the anther; at the base the wings extend between the column and the lip and are united. Anther in front of the produced wing of the column or between its lateral lobes, erect, 2-celled; connective often produced; pollinia 2 in each cell, friable.

A genus of probably over 40 species, mostly natives of Australia and New Zealand, one species only being found in New Caledonia, and two in the Malay Archipelago. It is remarkable from the lip being quite free from the column and resembling the petals and sepals, so that the perianth has little of the irregular appearance of an orchid, but rather resembles that of an *Ixia* or *Sisyrinchium*. The New Zealand species are much alike in habit and general appearance, and in most cases cannot be distinguished from one another when out of flower, or when dried. Even when in the flowering state they require careful study before their differential characters can be understood. The following analysis is in several respects imperfect, but is the best that I can offer in the present state of our knowledge. I have in my herbarium specimens of several additional forms, but they cannot be safely described until more complete material is available.

A. Cucullaria. *Column-wing extending behind the anther and usually overtopping it, hood-shpaed, variously lobed or fringed, the lateral lobes tipped with a dense brush of cilia.*

Column-wing with 3 short denticulate or fimbriate lobes at the back between the lateral lobes .. .. 1. *T. ixioides.*
Column-wing with a broad entire or emarginate lobe between the lateral lobes, which are shorter than it .. .. .. 2. *T. longifolia.*
Column-wing with a truncate or bifid scarcely hood-shaped lobe between the lateral lobes, which are longer than it. Flowers rose-coloured .. .. 3. *T. intermedia.*
Column-wing with a hood-shaped lobe between the lateral lobes, which are much longer than it. Sepals and petals linear-oblong .. .. 4. *T. Colensoi.*
Column-wing with a high but narrow bifid lobe between the lateral lobes, which first project horizontally, and then are erect .. 5. *T. pauciflora.*
Column-wing with a broad hood-shaped lobe between the lateral lobes; margins thick, fleshy, and denticulate. Flowers blue, sometimes spotted with brown .. .. 6. *T. decora.*
Column-wing with 3 separate lobes between the lateral lobes. Lateral lobes long, narrow, flat, fringed with branched fimbriae. Flowers blue, column yellow and violet .. .. .. 7. *T. aemula.*
Column-wing with a broad truncate middle lobe tuberculate on the back between the lateral lobes. Flowers large, lavender-blue, 1–1¼ in. diam. .. .. 8. *T. caesia.*

B. Macdonaldia. *Column-wing extending behind the anther but shorter than it and not hood-shaped, variously lobed or crenate or fimbriate.*

Tall, slender, 9–18 in. high. Flowers large, ¾–1 in. diam., blue-purple. Lateral lobes of column-wing flat, irregularly toothed 9. *T. pulchella.*
Tall, slender, 9–18 in. high. Flowers ¾–1 in. diam., blue-purple. Lateral lobes of column-wing flat, margins with branched fimbriae .. .. 10. *T. pachyphylla.*
Flexuous and wiry, 4–10 in. high. Flowers 1–3, ½ in. diam., flesh-coloured .. .. 11. *T. imberbis.*

C. Biaurella. *Column-wing not extending behind the anther, but with 2 prominent erect lateral lobes.*

Flexuous and wiry, 4–6 in. high. Lateral lobes of column erect, thick, smooth, and fleshy .. .. 12. *T. Matthewsii.*
Tall, 1–2 ft. high. Flowers 6–10, large, 1 in. diam., blue .. 13. *T. venosa.*
6–15 in. high, 1–4-flowered. Lateral lobe of the column-wing not so high as the narrow anther .. .. 14. *T. uniflora.*

T. aristata Lindl. See Blanch. Fl. Auck. 2nd. Ed. 215. Reichb. f. Hatch. Proc. L.S. N.S.W. 70: 1945.

1. **T. ixioides** *Swz. in Vet. Akad. Handl. Stockh.* xxi (1800) 228, t. 3. —Stem tall, slender, 9–18 in. high. Leaf rather long but shorter than the stem, narrow-linear, thick, channelled in front. Flowers 2–8 or more in a raceme 2–6 in. long, rather large, ¾ in. diam. Sepals, petals, and lip broadly oblong or elliptic-oblong, obtuse or subacute. Column short, stout, not ½ as long as the perianth; the broad wing continued behind the anther and overtopping it, 3-lobed at the back and with a lateral lobe on each side at the front angle; lateral lobes the highest, pointing forwards and upwards, linear, tipped with a small dense tuft of cilia; the 3 intermediate lobes broader and shorter, truncate, denticulate or crenate, the middle one usually crested on the back. Anther rather narrow, pointed, much longer than the rostellum.—*Hook. f. Fl. Tasm.* ii (1860) 6, t. 103B; *Benth. Fl. Austral.* vi (1873) 317; *Fitzgerald Austral. Orch.* ii (1888) pt. 3; *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 22; *Cheesem. Man. N.Z. Fl.* (1906) 669.

North Island: Not uncommon on clay hills from Mangonui and Kaitaia southwards to the Waikato River, Rotorua, and Taupo, *Berggren, R. H. Matthews! Petrie! H. Carse! T. F. C.* Sea-level to 1000 ft. September–November. Also a common Australian plant.

A handsome plant, with large blue flowers sometimes spotted with brown. The intermediate lobes at the top of the column are tipped with bright-yellow, below which is a transverse band of violet.

2. **T. longifolia** *Forst. Char. Gen.* (1786) 98, t. 49. — Very variable in size and degree of robustness, short or long, stout or slender, 3–18 in. high. Leaf often overtopping the flowers in short-stemmed specimens, narrow-linear or linear-lanceolate, varying in breadth from ⅛–¾ in. diam. or even more, flat or involute, thick and coriaceous or fleshy, grooved and nerved. Flowers 2–16 in a raceme 1–6 in. long or sometimes solitary, variable in size, ⅓–¾ in. diam., colour varying from white to pink or blue. Sepals and petals oblong-ovate or ovate-lanceolate, acute or acuminate; lip usually somewhat broader and more obtuse. Column short, stout; the wing continued behind the anther and much longer than it, 3-lobed; the middle lobe the highest, broad, rounded, hood-shaped and projecting forwards over the anther, emarginate or shallowly 2-lobed, margins smooth, entire; lateral lobes short, linear, terminated by a dense brush of white cilia. Anther much exceeding the rostellum.—*Hook. f. Handb. N.Z. Fl.* (1864) 270; *Benth. Fl. Austral.* vi (1873) 319; *Fitzgerald Austral. Orch.* i (1880) pt. 6. T. Forsteri *Swz. in Vet. Akad. Handl. Stockh.* xxi (1800) 228; *A. Rich. Fl. Nouv. Zel.* (1832) 165, t. 25, f. 2; *A. Cunn. Precur.* (1838) n. 309; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 243; *Cheesem. Man. N.Z. Fl.* (1906) 669; *Ill. N.Z. Fl.* ii (1914) t. 192A. T. stenopetala *Hook. f. Fl. Antarct.* i (1844) 69. T. nemoralis *and* T. purpureo-fusca *Col. in Trans. N.Z. Inst.* xvii (1885) 249. T. cornuta *Col. l.c.* xx (1888) 206.

Var. **alba** *Cheesem. n. var.*—Similar to the above, but sepals light greenish-purple; petals pure-white.—T. alba *Col. in Trans. N.Z. Inst.* xviii (1886) 272.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Abundant from the Three Kings Islands and the North Cape southwards. Sea-level to 4000 ft. *Makaika.* November–December. Also in Australia and Tasmania.

3. **T. intermedia** *Berggr. in Minneskr. Fisiog. Sallsk. Lund.* (1877) 21, t. 5, f. 21–24.—Small, slender, 8–12 in. high, with much of the habit of slender forms of *T. pauciflora* and *T. longifolia.* Leaves narrow-linear, channelled in front. Flowers 3–4 in a narrow raceme 1–2 in. long, small, $\frac{1}{3}$–$\frac{1}{2}$ in. diam., pale rose-coloured. Column short, not $\frac{1}{2}$ as long as the perianth, the wing continued behind the anther but shorter than it, 3-lobed; intermediate lobe bifid, not crested nor hooded, margin smooth; lateral lobes longer, narrow, pointing forwards and upwards, terminated by a small and thin tuft of cilia.—*Cheesem. Man. N.Z. Fl.* (1906) 670.

North Island: Apparently rare and local. Kaitaia, *R. H. Matthews!* Fairburn, *H. Carse!* Bay of Islands, *Berggren;* Cowes, Waiheke, *J. H. Harvey!* Rotorua and Waiotapu, *Mrs. H. J. Matthews!*

This is best distinguished by the small rose-coloured flowers, the narrow bifid intermediate lobe of the column-wing, and the narrow sparingly ciliate lateral lobes of the column.

4. **T. Colensoi** *Hook. f. Handb. N.Z. Fl.* (1864) 271.—"Very slender, 8–12 in. high. Leaf very narrow-linear, flexuous. Flowers 1–3, yellowish, on slender pedicels, $\frac{1}{3}$ in. broad. Sepals and petals very narrow, linear-oblong, acute. Column very short; appendages very long, subulate, erect, plumose at the tip. Anther with a long point."—T. pauciflora *Hook. f. Fl. Nov. Zel.* i (1853) 244 (*not of R. Br.*).

North Island: *Colenso* (Handbook).

I have seen no specimens that I can refer to this, and in the absence of any additional information have reproduced the description given in the Handbook.

5. **T. pauciflora** *R. Br. Prodr.* (1810) 314.—Stems slender, wiry, flexuous, 6–15 in. high, rarely more. Leaf much shorter than the stem, narrow-linear, $\frac{1}{10}$–$\frac{1}{5}$ in. broad, rarely more, thick and fleshy, longitudinally grooved, deeply channelled in front and thus concave. Flowers 1–6, $\frac{1}{3}$ in. long, usually pale-blue or whitish-blue. Petals and sepals narrow-ovate or ovate-lanceolate, acute. Column short, stout, the wing continued behind the anther and longer than it, 3-lobed, the middle lobe much the largest and also the highest, narrower than in *T. longifolia,* thick and swollen, projecting over the anther, deeply emarginate or 2-lobed, brownish-red at the base, bright-yellow towards the tip; lateral lobes smaller at the base, projecting forwards almost horizontally, then suddenly bent upwards and erect, terminated by a dense brush of white cilia. Anther broad, connective produced into a short point.—*Cheesem. in Trans. N.Z. Inst.* xlviii (1916) 214.

North Island: *Leptospermum*-clad hills in the northern portion of the Auckland Provincial District, abundant north of the Waikato River, and probably extending much further south, *T. F. C., W. Townson! H. B. Matthews! H. Carse!* and others. October–November.

Closely allied to *T. longifolia,* with which it was united by Mr. Bentham. But it differs in its smaller size and more slender habit; in its narrower and deeply channelled leaf; in the smaller flowers; and especially in the middle lobe of the column-wing, which is deeply emarginate or 2-lobed, whereas it is much broader, more hood-shaped, and barely emarginate in *T. longifolia. T. pauciflora* is not uncommon in eastern Australia.

6. **T. decora** *Cheesem. Man. N.Z. Fl.* (1906) 1151.—Stem slender, 6–12 in. high or more. Leaf shorter than the stem, narrow-linear, thick and fleshy, channelled, $\frac{1}{6}$–$\frac{1}{3}$ in. broad; empty bracts 1–3, the upper broader

and more membranous. Flowers 1–4, about ½ in. diam., dark-blue, the two lateral petals obscurely spotted with brown. Sepals and petals ovate-oblong, subacute. Column short, stout, about ½ the length of the perianth, the wing continued behind the anther and longer than it, 3-lobed; middle lobe the shortest but exceeding the anther, hood-shaped, truncate, the margin thick and fleshy and denticulate, the back minutely warted, the anterior angle on each side slightly produced and acute; lateral lobes much larger than the middle lobe, pointing forwards, terminated by a dense rounded brush of cilia. Anther broad; connective terminating in a stout horn-like point.

North Island: Taumarere, Bay of Islands, *J. H. Harvey!* also at Cowes, Waiheke Island; Rotorua, *Mrs. H. J. Matthews!* Tirau, Upper Thames Valley, Waimarino Plains, hills near the base of Ngauruhoe, summit of Mount Kakaramea, altitude 4500 ft., *T. F. C.* Altitudinal range, sea-level to 4500 ft. December–January.

7. **T. aemula** *Cheesem. in Trans. N.Z. Inst.* li (1919) 94.—Stems stout or slender, 6–16 in. high. Leaf shorter than the stem, narrow-linear, thick, channelled in front. Cauline leaves or empty bracts 2, short, sheathing. Flowers 3–8, about ½ in. diam., blue, rather closely placed in a raceme 1½–4 in. long. Sepals or petals oblong or ovate-oblong, obtuse or subacute. Column short, stout, broad at the base, narrowed above, winged, the wing extending behind the anther and free from it, except at the base, 5-lobed; the 2 lateral lobes twice the length of the others, flat, narrow, erect, fringed with numerous branched fimbriae; middle lobe short and broad, thickened and denticulate at the tip, smooth or minutely tuberculate on the back; the two intermediate lobes distinct from the central one, broad, thick and fleshy, jagged at the top. Anther broad, connective produced into a pointed tip that just overtops the level of the median lobe of the column-wing.

North Island: *Leptospermum*-clad hills from Kaitaia (Mongonui County) to Auckland, *H. B. Matthews! T. F. C.*

Doubtless closely allied to *T. ixioides* and the Australian *T. canaliculata*, but differing in the lateral lobes of the column being much longer, flattened and more copiously penicillate; and the middle lobe, although denticulate at the top, is not conspicuously warted or crested at the back. The flowers appear to be invariably blue; but the column is surrounded by a narrow band of violet just below the lobes, above which the colour is bright-yellow.

8. **T. caesia** *Petrie in Trans. N.Z. Inst.* li (1919) 107.—Stem tall, slender, 1–3 ft. high. Leaf shorter than the stem, sheathing at the base, linear, fleshy, concave and grooved above. Empty bracts 2–3, sheathing, acuminate. Flowers 4–5, large, handsome, lavender-blue, 1–1¼ in. diam. Sepals and petals oblong or oblong-ovate, acute or subacute or apiculate. Column short, stout, not ½ the length of the perianth, wing continued behind the anther but shorter than it, 3-lobed; middle lobe broad, thick and fleshy, tuberculate on the back, subtruncate along the top, yellowish-brown; lateral lobes as long as the anther, thin and flattened, margins cut into numerous fimbriate branched processes. Anther broad, connective produced into a slightly grooved tip.

North Island: *Leptospermum*-clad hills at Birkdale, near Auckland, *H. B. Matthews!*

9. **T. pulchella** *Hook. f. Fl. Nov. Zel.* i (1853) 244.—Stem tall, slender, often flexuous, 9–18 in. high or even more. Leaf shorter than the stem, long, linear, fleshy, grooved and channelled; empty bracts 2–3, sheathing. Flowers 3–8 in a raceme from 2–6 in. long, large, handsome, blue-purple, ¾–1 in. diam. Sepals and petals broadly oblong or obovate, obtuse. Column less than ½ as long as the perianth, the wing continued behind the anther but much shorter than it, 3-lobed; middle lobe short and broad, emarginate or truncate; lateral lobes much longer than the middle lobe and almost equalling the anther, erect, lanceolate, acuminate, coarsely toothed. Anther broad, connective produced into a stout horn-like point. —*Handb. N.Z. Fl.* (1864) 271; *Cheesem. Man. N.Z. Fl.* (1906) 670; *Ill. N.Z. Fl.* ii (1914) t. 192B.

North Island: Clay hills from the North Cape to Rotorua, not uncommon. Sea-level to 1200 ft. November–December.

A handsome and well-marked species, easily distinguished by the large blue-purple flowers, broad obtuse petals and sepals, long erect coarsely jagged (not ciliate) lateral lobes of the column-wing, and broad and short middle lobe, which is much lower than the anther. I have seen no South Island specimens, and suspect that Monro's and Lyall's plants, mentioned by Hooker in the Handbook, are referable to *T. pachyphylla.*

10. **T. pachyphylla** *Cheesem. Man. N.Z. Fl.* (1906) 1151.—Stem tall, stout or rather slender, 9–18 in. high or more. Leaf shorter than the stem, usually very thick and fleshy, grooved and channelled, variable in breadth, sometimes as much as ¾ in. across; empty bracts 2 or 3, thick and fleshy, sheathing. Flowers 3–6 or more in a raceme, large and handsome, ¾–1 in. diam., blue-purple. Sepals and petals oblong-ovate or broadly oblong, subacute. Column short, stout, about ½ as long as the perianth, the wing continued behind the anther but hardly as long as it, 3-lobed; middle lobe short, broad, indistinctly hood-shaped, truncate at the top with an even or denticulate margin; lateral lobes longer than the middle one, erect or pointing forwards, flattened, the margins provided with numerous simple or branched fimbriae. Anther broad; connective produced into a stout horn-like point which usually overtops the middle lobe of the column-wing.

South Island: Nelson—Vicinity of Westport, abundant, *W. Townson!* Westland —Kumara, *J. W. Brame!*

This has been confused with *T. pulchella*, from which, however, it totally differs in the structure of the column. In *T. pulchella* the middle lobe of the column-wing is much shorter than the anther, while the lateral lobes are barely as long as it, and are irregularly toothed or jagged, and not at all ciliate or fimbriate. In the present species the middle lobe almost equals the anther, while the lateral lobes are longer than it, and are provided with numerous fimbriae.

11. **T. imberbis** *Hook. f. Fl. Nov. Zel.* i (1853) 244.—Stem slender, wiry, often flexuous, 4–12 in. high. Leaf much shorter than the stem, narrow-linear, flexuous, thick and fleshy, grooved in front. Flowers 1–3, rarely more, short and broad, cup-shaped, ½ in. diam., flesh-coloured, rarely white or cream-coloured. Sepals and petals ⅓ in. long, broadly oblong or obovate-oblong, obtuse or apiculate. Column less than ½ as long as the perianth; the wing continued behind the anther but shorter than it, 3-lobed; middle lobe broad, truncate or obscurely 2-lobed, minutely warted upon the back, margin thick, entire; lateral lobes longer, pointing forwards and upwards, triangular, acute, irregularly denticulate,

Lee. L. S. NSD. 90-1945.

without cilia. Anther large, connective produced into a blunt point much exceeding the column-wing.—*Handb. N.Z. Fl.* (1864) 271; *Cheesem. Man. N.Z. Fl.* (1906) 671.

North Island: Clay hills from the North Cape to Rotorua, not uncommon. Sea-level to 1500 ft. October–November.

In the original description the flowers are said to be yellow, but they are usually flesh-coloured. It is very closely allied to the Australian *T. carnea*, and may be identical with it.

12. **T. Matthewsii** *Cheesem. in Trans. N.Z. Inst.* xliii (1910) 177.—Stem wiry, flexuose, 4–6 in. high. Leaf solitary, sheathing the stem at the base, the sheath finely and closely puberulous; lamina 1½–2½ in. long, much expanded at the base, and then suddenly narrowed into a linear blade, which is usually spirally twisted so as to coil round the stem; margins involute. Bracts 2, the lower one below the middle of the stem, the upper almost close to the flower, both broad and sheathing. Flower solitary, large for the size of the plant, ½–¾ in. diam. Perianth-segments all similar, lanceolate or oblong-lanceolate, acute or shortly acuminate, dark purplish-blue with darker longitudinal veins. Column much shorter than the perianth-segments, not produced at the back behind the anther, but furnished with two large lateral lobes which equal the anther in height, and which are oblong or oblong-falcate, obtuse, somewhat flattened but thick and fleshy, not lobed nor furnished with cilia. Sometimes there are evidences of a slight crest connecting the lateral lobes at the base. Anther very large, oblong, obtuse. Base of column purplish; lateral lobes and anther bright-yellow.

North Island: Mongonui County, low hills between Lake Tongonge and the coast, rare, *R. H. Matthews* and *H. B. Matthews*.

A charming little plant, worthily dedicated to its discoverer, who has added more to our knowledge of the New Zealand orchids than any other observer of late years. It is closely allied to the Western Australian *T. variegata*, principally differing in the much smaller size, in the solitary flowers, and in the column not crested on the back.

13. **T. venosa** *R. Br. Prodr.* (1810) 314.—Stem stout or slender, 9–18 in. high or more. Leaf shorter than the stem, narrow-linear, thick, channelled. Flowers 3–6, large, handsome, purplish-blue, 1 in. diam. Sepals and petals ½ in. long, oblong or elliptic-oblong, obtuse or minutely apiculate, conspicuously veined; lip obovate, obtuse. Column short, stout, not ½ the length of the perianth; wing not continued behind the anther, but with 2 erect lateral lobes which exceed the anther, lobes narrow-triangular, 1–2-toothed near the tip, which usually is spirally twisted inwards. Anther rather short, ovate, connective narrowed into a short bifid beak not so long as the two lateral lobes.—*Benth. Fl. Austral.* vi (1873) 323; *Cheesem. Man. N.Z. Fl.* (1906) 671. Epiblema grandiflorum *Buch. in Trans. N.Z. Inst.* xiv (1882) 357 (*not of R. Br.*).

North Island: Rukuhia Swamp, near Hamilton, *H. B. Matthews! T. F. C.*; also *Sphagnum* swamps at Tirau and Rotorua, Omatangi, near Lake Taupo, *Berggren*. Taranaki—Ngaire Swamp, *T. F. C.* Wellington—Mungaroa Swamp, *H. H. Travers, T. Kirk!* Altitudinal range 500–2000 ft. December–January.

14. **T. uniflora** *Hook. f. Fl. Antarct.* i (1844) 70.—Stem slender, 6–12 in. high or more. Leaf much shorter than the stem, very narrow-linear, channelled. Flowers 1–4, large, handsome, blue-purple, ¾ in. diam. Sepals

and petals obovate-oblong, obtuse or apiculate, veined; lip broader, obovate. Column short and stout, less than ½ the length of the perianth, wing reduced to 2 linear-triangular lateral lobes not connected by a rim or crest behind the anther, tip obscurely notched, usually twisted inwards. Anther large, broadly ovate, the connective produced into a bifid beak which overtops the lateral lobes.—*Fl. Nov. Zel.* i (1853) 244; *Handb. N.Z. Fl.* (1864) 271; *Cheesem. Man. N.Z. Fl.* (1906) 672; *Ill. N.Z. Fl.* ii (1914) t. 193A.

North and South Islands, Stewart Island, Auckland Islands: From Rotorua southwards, abundant in upland districts. Sea-level to 3500 ft. December–January.

The name *uniflora* is misleading, as the flowers are often more than one. The species is very closely allied to the Tasmanian *T. cyanea* Lindl. (Hook. f. Fl. Tasm. (1860) t. 102), and may prove identical with it.

7. **ORTHOCERAS** R. Br.

Glabrous terrestrial herbs. Root of 1 or 2 ovoid tubers and numerous fleshy fibres. Leaves few, near the base of the stem, narrow-linear. Flowers rather large, sessile in a lax spike; bracts sheathing, acute. Upper sepal erect, incurved, deeply concave; lateral longer, narrow-linear or almost filiform, terete, erect. Petals short, erect, narrow, flat. Lip affixed to the base of the column, spreading, 3-lobed; lateral lobes broad; middle lobe large, ovate; disc with a thick callus. Column short, stout, upper part with 2 lateral erect lobes equalling the anther. Anther large, erect or slightly incurved, 2-celled; pollinia powdery.

One species only is known, found in both Australia and New Zealand.

1. **O. strictum** *R. Br. Prodr.* (1810) 317.—Stem stout or slender, rigid, erect, wiry, 9–24 in. high. Leaves several near the base of the stem, sheathing, 2–9 in. long, linear or almost filiform, channelled, margins involute; above the leaves there are usually 2 or 3 long sheaths with short erect laminae. Spike 1–9 in. long, 3–12-flowered; flowers rather lax, green, greenish-purple or brownish-purple; bracts acuminate, the lower ones usually exceeding the ovary. Upper sepal ⅓–½ in. long, when spread out almost orbicular, much incurved, deeply concave; lateral filiform, erect or diverging, ½-1 in. long. Petals thin, notched at the tip. Lip spreading or deflexed; lateral lobes broad, oblique; middle lobe much larger, ovate; disc with a large variously shaped callus.—*A. Cunn. Precur.* (1836) n. 310; *Benth. Fl. Austral.* vi (1873) 332; *Fitzgerald Austral. Orch.* i (1880) pt. 3; *Cheesem. Man. N.Z. Fl.* (1906) 672. O. Solandri *Lindl. Gen. et Sp. Orch.* (1830) 512; *Hook. f. Fl. Nov. Zel.* i (1853) 243; *Handb. N.Z. Fl.* (1864) 273. O. rubrum *Col. in Trans. N.Z. Inst.* xviii (1886) 273. O. caput-serpentis *Col. l.c.* xxii (1890) 490. Diuris novae-zealandiae *A. Rich. Fl. Nouv. Zel.* (1832) 163, t. 25, f. 1.

North Island: Dry hills from the North Cape southwards, not uncommon. South Island: Various localities in the Nelson Provincial District, *Bidwill, T. Kirk! T. F. C.* Sea-level to 2500 ft. December–January.

This species ranges in Australia from the north of New South Wales to Victoria and South Australia. According to Mr. Bentham, the plants from the two countries do not differ in the slightest particular.

M. pavillosa R. Br. Prodr. 1810. 321.
in N.Z. accidg. to Hupk. Orchidographer
See Black. Fl. S. Austr. p. 21. 2nd Ed. p. 217

8. **MICROTIS** R. Br.

Glabrous terrestrial herbs; root of rounded tubers on fleshy fibres. Leaf solitary, long, narrow, terete, opened out near the stem and then continuous with the closed sheath. Flowers small, green, numerous, densely spicate, usually spreading or reflexed. Upper sepal erect, broad, concave, incurved; lateral lanceolate or oblong, spreading or recurved. Petals similar to the lateral sepals or smaller. Lip sessile at the base of the column, spreading, oblong, obtuse, truncate or 2-lobed, usually with calli near the base. Column very short, almost terete, upper part with 2 auricles or wings. Anther terminal, erect, 2-celled; pollinia 4, powdery.

The genus consists of 6 species inhabiting Australia, one of them extending to New Zealand. A seventh species has also been described from the Malay Archipelago. The genus has the habit and general appearance of *Prasophyllum*, but differs in the flowers not being reversed, and in the auricles of the column.

1. **M. unifolia** *Reichenbach f. Beitr. Syst. Pfl.* 62.—Very variable in size, degree of robustness, and number of flowers. Stems stout or slender, 3–24 in. high. Leaf terete, fistular, exceeding the spike or shorter than it. Spike ½–6 in. long; flowers few or many, close-set or rather distant, minute, green, pedicels short; bracts small. Upper sepal broadly ovate, acute, deeply concave; lateral oblong, deflexed. Petals shorter, spreading. Lip horizontal or deflexed, oblong, obtuse or 2-lobed; margins much crisped; disc with 2 calli at the base and usually with an irregularly shaped tubercle or swelling near the tip. Column very short, stout; upper part with 2 small auricles. Pollinia attached to a very short caudicle.—M. porrifolia *R. Br. Prodr.* (1810) 320; *Hook. f. Fl. Nov. Zel.* i (1853) 245; *Handb. N.Z. Fl.* (1864) 266; *Benth. Fl. Austral.* vi (1873) 347; *Fitzgerald Austral. Orch.* ii (1888) pt. 1; *Cheesem. Man. N.Z. Fl.* (1906) 673. M. Banksii *A. Cunn. in Bot. Mag.* (1835) sub. t. 3377, *and Precur.* (1836) n. 311; *Raoul Choix* (1846) 41. M. longifolia *Col. in Trans. N.Z. Inst.* xvii (1885) 247. M. papillosa *Col. l.c.* xviii (1886) 269. Epipactis porrifolia *Swz. in Vet. Acad. Stockh.* (1800) 233. Ophrys unifolia *Forst. f. Prodr.* (1786) n. 311.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: Abundant throughout. Sea-level to 2500 ft. October–December.

There appear to be differences in the shape and size of the calli on the lip, the shape of its extremity, and the extent to which the margin is crisped. The fertilization has been described by Thomson in Trans. N.Z. Inst. xi (1879) 422.

9. **PRASOPHYLLUM** R. Br.

Terrestrial glabrous herbs. Root of globose or ovoid tubers. Leaf solitary; sheath usually long; lamina terete, long or short, sometimes reduced to a short erect point. Flowers small, sessile in a lax or dense spike, reversed so that the lip is uppermost, usually abruptly bent at the top of the ovary and consequently spreading or reflexed. Upper sepal (inferior by the reversion of the flower) lanceolate or oblong, concave, usually arched over the column; lateral (superior) as long or rather longer, lanceolate or linear, free or more or less connate. Petals equalling the sepals or shorter, lanceolate or linear. Lip superior, sessile or shortly clawed, or sessile on the produced foot of the column, usually erect at the base and concave, spreading or recurved above, ovate or lanceolate, undivided; margins entire or undulate; disc with an adnate plate or longitudinally thickened

along the median line. Column very short, not winged, but furnished with 2 erect lateral lobes; rostellum usually long, erect. Anther erect, placed behind the rostellum which often exceeds it, 2-celled; pollinia attached by a linear caudicle to the rostellum.

Species about 30, all confined to Australia, with the exception of 2 from New Caledonia, and 4 from New Zealand, 2 of which seem to be the same as Australian species. The genus is closely allied to *Microtis*, but is at once distinguished by the reversed flowers and large lateral lobes to the column.

A. Euprasophyllum. *Lip sessile at the base of the column. Perianth* $\frac{1}{3}$–$\frac{1}{2}$ *in. long.*

Tall, 1–3 ft. high. Flowers $\frac{1}{4}$–$\frac{1}{3}$ in. Lip large, with a conspicuous recurved lamina; adnate plate not nearly reaching the tip .. 1. *P. patens.*
Smaller, 4–12 in. Flowers $\frac{1}{5}$ in. Lip shorter, with a smaller recurved lip; adnate plate extending almost to the tip .. .. 2. *P. Colensoi.*

B. Genoplesium. *Leaf reduced to a sheathing bract just under the spike. Lip articulated on to a flat ribband-like projection from the base of the column, usually mobile. Flowers very small,* $\frac{1}{10}$–$\frac{1}{12}$ *in. long.*

Perianth pointing downwards, green. Lateral sepals ovate-lanceolate, not tipped with a gland. Lip oblong .. .. .. 3. *P. pumilum.*
Perianth horizontal, reddish. Lateral sepals narrow-lanceolate, acuminate, tipped by a minute gland. Lip lanceolate .. 4. *P. rufum.*

1. **P. patens** *R. Br. Prodr.* (1810) 318.—Stem stout or slender, 1–3 ft. high. Leaf sheathing the stem half-way up or rather more, the lamina shorter or longer than the spike. Spike rather lax, 2–5 in. long, many-flowered; bracts small, broad, obtuse. Flowers $\frac{1}{4}$–$\frac{1}{3}$ in. long, pale yellowish-green or whitish, sweet-scented. Ovary obovoid. Upper sepal ovate, acute, concave; lateral rather longer, lanceolate, quite free. Petals linear-oblong, obtuse. Lip sessile, as long as the sepals, erect at the base and then suddenly reflexed between the lateral sepals; adnate plate narrower than the disc and not extending much further up than the flexure of the lip; margins broad, thin, undulate. Column short; lateral lobes linear-oblong, obtuse, almost as long as the narrow erect rostellum, entire. Anther large, pointed, not quite equalling the rostellum.—*Hook. f. Fl. Tasm.* ii (1860) 11, t. 111; *Benth. Fl. Austral.* vi (1873) 339; *Cheesem. Man. N.Z. Fl.* (1906) 675.

North Island: Auckland—Swamps at Maungatapere, Whangarei, *H. Carse!* Great Barrier Island, *T. Kirk!* Paeroa Range, near Waiotapu, *K. W. Allison!* Taranaki—Ngaire Swamp, abundant, *T. F. C.* December–January.

Easily distinguished from *P. Colensoi* by the much greater size, larger paler flowers, and longer lip, which has a much more conspicuous recurved lamina, the adnate plate not extending to the tip. The lateral lobes of the column are also much longer. It agrees well with Australian specimens of *P. patens*, except that the spike is usually denser.

2. **P. Colensoi** *Hook. f. Fl. Nov. Zel.* i (1853) 241.—Stem stout or slender, erect, 4–14 in. high. Leaf sheathing the stem for $\frac{3}{4}$ its length or even more; lamina shorter than the spike or equalling it. Spike 1–3 in. long, many-flowered; bracts as short as the pedicel, broad, obtuse. Flowers about $\frac{1}{5}$ in. long, dull-green or greenish-brown, slightly fragrant; ovary obovoid, gibbous. Upper sepal ovate-oblong, acute, concave; lateral rather longer, connate at the very base, lanceolate, acute, curved backwards. Petals linear-oblong, obtuse. Lip shorter than the sepals, sessile, ovate, tip acuminate, shortly recurved, adnate plate extending almost to the tip, margins undulate. Column very short, lateral lobes

See Hatch Trans 7.5 : 369 : 1943

not common. April [illegible].

4. **P rufum** *R. Br. Prodr.* (1810) 319.—Very similar in size and habit to *P. pumilum*, and like it with the leaf reduced to a sheathing bract just below the spike, the lamina very short and subulate. Spike few- or many-flowered, $\frac{1}{2}$–$\frac{3}{4}$ in. long. Flowers still more minute than in *P. pumilum*, the perianth about $\frac{1}{12}$ in. long, horizontal, reddish or yellowish. Upper sepal ovate, acuminate, concave; the lateral much longer, quite free, lanceolate, acuminate, the points tipped with a small gland. Petals small, lanceolate, shorter than the upper sepal. Labellum articulate on a flat ribband-like projection from the foot of the column, mobile, lanceolate, acute, truncate at the base, adnate plate occupying most of the disc, thickest along the margins. Column very short, the lobes rather narrow, 2-toothed at the tip. Anther large, apiculate, overtopping the small rostellum.—*Benth. Fl. Austral.* vi (1873) 344; *Fitzgerald Austral. Orch.* ii (1891) pt. 4; *Cheesem. Man. N.Z. Fl.* (1906) 676. P. nudum *Hook. f. Fl. Nov. Zel.* i (1853) 242; *Handb. N.Z. Fl.* (1864) 272. P. tunicatum *Hook. f. Fl. Nov. Zel.* i (1853) 242. (?) P. variegatum *Col. in Trans. N.Z. Inst.* xx (1888) 208.

North Island: Auckland—Birkdale, a few specimens only, *H. B. Matthews!* Waimarino Plains, *E. Phillips Turner!* Paeroa Range, *K. W. Allison!* Hawke's Bay—Lake Tutira, *H. Guthrie-Smith!* Wellington—Lake Taupo, Te Hawara, Port Nicholson, *Colenso* (Handbook); Kaitoke; Day's Bay, *B. C. Aston.* South Island: Marlborough—Port Underwood and Kenepuru, *J. H. Macmahon!* Nelson—Westport, *J. E. Holloway!*

This corresponds fairly well with the plate of *P. rufum* given by Mr. Fitzgerald in his "Australian Orchids." It is distinguished from the preceding species by the smaller horizontal usually reddish flowers, narrower lateral sepals tipped by a minute gland, much narrower lip, the adnate plate on which is thickest on the edges, and in the narrower lateral lobes of the column.

PRASOPHYLLUM R.Br.
KEY TO THE NEW ZEALAND SPECIES

1. Labellum sessile, lamina reddish-green . . . . . 2.
   Labellum on a very short, rigid claw, lamina broad, white, margins prominently crenulate . . . . . suttonii
   Labellum on a narrow, movable claw . 3.
2. Margins flat, callus pale, extending only to the curve . . . . . rogersii
   Margins undulate, callus green, extending almost to the tip . . . . . colensoi
3. Labellum green, mucronate, margins entire, callus of several inconspicuous ridges . . . . . pumilum
   Labellum dark-red, acuminate, margins ciliate at the tip, callus with a prominent linear cleft . . . nudum

E. D. Hatch, Trans. Roy. Soc. N.Z., Vol.76, Pt.3, pp.289-293.

[illegible], as long as the sepals, erect at the base and then suddenly reflexed between the lateral sepals; adnate plate narrower than the disc and not extending much further up than the flexure of the lip; margins broad, thin, undulate. Column short; lateral lobes linear-oblong, obtuse, almost as long as the narrow erect rostellum, entire. Anther large, pointed, not quite equalling the rostellum.—*Hook. f. Fl. Tasm.* ii (1860) 11, t. 111; *Benth. Fl. Austral.* vi (1873) 339; *Cheesem. Man. N.Z. Fl.* (1906) 675.

North Island: Auckland—Swamps at Maungatapere, Whangarei, *H. Carse!* Great Barrier Island, *T. Kirk!* Paeroa Range, near Waiotapu, *K. W. Allison!* Taranaki—Ngaire Swamp, abundant, *T. F. C.* December–January.

Easily distinguished from *P. Colensoi* by the much greater size, larger paler flowers, and longer lip, which has a much more conspicuous recurved lamina, the adnate plate not extending to the tip. The lateral lobes of the column are also much longer. It agrees well with Australian specimens of *P. patens*, except that the spike is usually denser.

2. **P. Colensoi** *Hook. f. Fl. Nov. Zel.* i (1853) 241.—Stem stout or slender, erect, 4–14 in. high. Leaf sheathing the stem for ¾ its length or even more; lamina shorter than the spike or equalling it. Spike 1–3 in. long, many-flowered; bracts as short as the pedicel, broad, obtuse. Flowers about ⅕ in. long, dull-green or greenish-brown, slightly fragrant; ovary obovoid, gibbous. Upper sepal ovate-oblong, acute, concave; lateral rather longer, connate at the very base, lanceolate, acute, curved backwards. Petals linear-oblong, obtuse. Lip shorter than the sepals, sessile, ovate, tip acuminate, shortly recurved, adnate plate extending almost to the tip, margins undulate. Column very short, lateral lobes

See Hatch Trans 75 : 369 : 1945
" " 76 289 1947

broadly notched, shorter than the rostellum. Anther broad, obtuse, not equalling the rostellum.—*Handb. N.Z. Fl.* (1864) 272; *Cheesem. Man. N.Z. Fl.* (1906) 675; *Ill. N.Z. Fl.* ii (1914) t. 193B.

North and South Islands, Stewart Island, Antipodes Island: From the North Cape southwards, but rare and local to the north of Lake Taupo. Sea-level to 4500 ft. November–January.

A most abundant subalpine plant all through the mountains of the South Island. For some remarks on the fertilization, see a paper by Mr. Thomson in the Trans. N.Z. Inst. xi (1879) 435.

3. **P. pumilum** *Hook. f. Fl. Nov. Zel.* i (1853) 242.—Very slender, 6–16 in. high. Stem with a lacerated fibrous sheath at the base. Leaf reduced to a sheathing bract near the spike; lamina ½–1 in. long, erect, usually reaching about half-way up the spike. Spike dense, few- or many-flowered, ½–1½ in. long. Flowers minute, the perianth about $\frac{1}{10}$ in. long, curved, pointing downwards, greenish. Upper sepal ovate, acuminate, concave; lateral rather longer, free, ovate-lanceolate, acuminate. Petals the same shape as the lateral sepals, but shorter, and with the tips almost aristate. Lip articulate on a flat ribband-like projection from the foot of the column, mobile, oblong, acute, truncate at the base, not ciliate, disc almost wholly occupied by a thick adnate plate, which is obscurely 3-grooved towards the base. Column short, the lateral lobes broad, obliquely truncate and irregularly 2-3-notched at the tip. Anther large, apiculate, overtopping the small rostellum.—*Handb. N.Z. Fl.* (1864) 273; *Cheesem. Man. N.Z. Fl.* (1906) 675; *Ill. N.Z. Fl.* ii (1914) t. 194A.

North Island: Auckland—Dry hills from the North Cape to the Middle Waikato, not common. April–June.

4. **P rufum** *R. Br. Prodr.* (1810) 319.—Very similar in size and habit to *P. pumilum*, and like it with the leaf reduced to a sheathing bract just below the spike, the lamina very short and subulate. Spike few- or many-flowered, ½–¾ in. long. Flowers still more minute than in *P. pumilum*, the perianth about $\frac{1}{12}$ in. long, horizontal, reddish or yellowish. Upper sepal ovate, acuminate, concave; the lateral much longer, quite free, lanceolate, acuminate, the points tipped with a small gland. Petals small, lanceolate, shorter than the upper sepal. Labellum articulate on a flat ribband-like projection from the foot of the column, mobile, lanceolate, acute, truncate at the base, adnate plate occupying most of the disc, thickest along the margins. Column very short, the lobes rather narrow, 2-toothed at the tip. Anther large, apiculate, overtopping the small rostellum.—*Benth. Fl. Austral.* vi (1873) 344; *Fitzgerald Austral. Orch.* ii (1891) pt. 4; *Cheesem. Man. N.Z. Fl.* (1906) 676. P. nudum *Hook. f. Fl. Nov. Zel.* i (1853) 242; *Handb. N.Z. Fl.* (1864) 272. P. tunicatum *Hook. f. Fl. Nov. Zel.* i (1853) 242. (?) P. variegatum *Col. in Trans. N.Z. Inst.* xx (1888) 208.

North Island: Auckland—Birkdale, a few specimens only, *H. B. Matthews!* Waimarino Plains, *E. Phillips Turner!* Paeroa Range, *K. W. Allison!* Hawke's Bay—Lake Tutira, *H. Guthrie-Smith!* Wellington—Lake Taupo, Te Hawara, Port Nicholson, *Colenso* (Handbook); Kaitoke; Day's Bay, *B. C. Aston.* South Island: Marlborough—Port Underwood and Kenepuru, *J. H. Macmahon!* Nelson—Westport, *J. E. Holloway!*

This corresponds fairly well with the plate of *P. rufum* given by Mr. Fitzgerald in his "Australian Orchids." It is distinguished from the preceding species by the smaller horizontal usually reddish flowers, narrower lateral sepals tipped by a minute gland, much narrower lip, the adnate plate on which is thickest on the edges, and in the narrower lateral lobes of the column.

10. **CALEANA** R. Br.

Glabrous terrestrial herbs. Root of small rounded tubers on fleshy fibres. Leaf solitary, linear or lanceolate or oblong. Flowers solitary or 2–4 in a terminal raceme; bracts acute. Sepals and petals subequal, all linear; the upper sepal erect, the lateral sepals and petals spreading or deflexed (but the position apparently reversed through the ovary being recurved). Lip uppermost, jointed on to the base of the column or to a projection from it, mobile; claw linear, incurved; lamina ovate or oblong, peltate, undivided, entire, smooth or tuberculate. Column elongate, sometimes produced at the foot, broadly winged throughout its whole length, concave. Anther terminal, erect, 2-celled; pollinia 2-partite, granular.

A small genus of 4 species, all of them natives of Australia, 1 extending to New Zealand.

1. **C. minor** *R. Br. Prodr.* (1810) 329.—Stem slender, wiry, almost filiform, 2–8 in. high, usually tinged with red. Leaf radical, about $\frac{1}{2}$ as long as the stem, rather fleshy, channelled. Flowers 1–4, about $\frac{1}{3}$ in. long including the ovary, greenish tinged with red, reversed; pedicels $\frac{1}{4}$-$\frac{1}{2}$ in.; bracts minute, acute. Sepals and petals narrow-linear, slightly dilated above the middle, nearly equal; upper sepal attached just above the top of the ovary, the lateral affixed to the basal projection of the column. Lip uppermost, very remarkable in shape; the lower portion claw-like and articulated on to the basal projection of the column; the upper part expanded into a broad lamina which is peltately attached to the claw; lamina convex above and covered with close-set reddish tubercles, which are largest towards the margins, under-surface smooth, concave. Column rather long, with a broad basal projection, broadly winged all round, concave, forming a horizontally placed cup or pouch.—*Benth. Fl. Austral.* vi (1873) 366; *T. Kirk in Trans. N.Z. Inst.* xxiv (1893) 425; *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 411, *and Man. N.Z. Fl.* (1906) 677.

North Island: Auckland—Kaitaia, *R. H. Matthews! H. Carse!* Rotorua, *Spencer!* Waiotapu, *H. J. Matthews!* December–January.

A most remarkable little plant. The column is horizontally placed, forming a broad pouch; the lamina of the lip, when at rest, is elevated by the slender elastic claw, and swings directly above it. When an insect alights on the lamina it overbalances, shutting up the insect within the concavity of the column. For a full account of the fertilization of the genus, reference should be made to Mr. Fitzgerald's magnificent work on Australian Orchids (vol. i, pt. 6).

11. **PTEROSTYLIS** R. Br. (1810) 326. nom. cons.

Terrestrial leafy herbs. Root of small rounded tubers on long fleshy fibres. Leaves radical and cauline, either all similar or the radical broader and ovate or oblong, often subrosulate; the cauline lanceolate or linear or reduced to sheathing bracts. Flowers large or small, greenish, usually solitary, rarely several in a terminal raceme. Upper sepal erect, incurved, concave, conniving with the petals and forming a broad boat-shaped hood (*galea*). Lateral sepals adnate at the base to the foot of the column, more or less connate into an erect or recurved 2-lobed lower lip; the lobes often drawn out into long acuminate points. Petals lanceolate, falcate. Lip attached by a short claw to the basal projection of the column, mobile; lamina linear or oblong, produced at the base above the claw into a long or short usually curved appendage. Column elongated, incurved, furnished

See Hatch, T.R.S. N.Z. 77: 234–246 for revision.

" Reuph Orch. N.S.W.

on each side of the rostellum with a quadrangular or hatchet-shaped membranous wing, the base produced into a horizontal projection. Stigma on the face of the column below the wings, oblong. Anther terminal, erect, 2-celled; pollinia 4, granular, free.

About 50 species are known. Of the 13 found in New Zealand, 2 are common Australian plants, the others are endemic. The remainder of the genus is Australian, with the exception of 2 species in New Caledonia. The mode of fertilization is most curious, and is well worth an attentive study. The upper sepal and petals connive, and form a hood, at the back of which the column is situated. The irritable lip hangs out of the entrance to the flower, and forms a convenient landing-place for insects. When touched by an insect it springs up, carrying the insect with it, and imprisoning it within the flower. The insect can only escape by crawling up the column and passing between the two membranous projecting wings, emerging directly in front of the anther. In doing this, it is first smeared with viscid matter from the projecting rostellum, and then drags away the pollinia, which can hardly fail to adhere to its sticky body. When visiting another flower, it must pass over the stigma before escaping, and is almost certain to leave some of the pollinia on its viscid surface. For a fuller account, see a paper by myself in *Trans. N.Z. Inst.* v (1873) 352.

A. Antennaea. *Lower lip erect, its lobes narrowed into long points embracing the galea.*

* No broad radical leaves. Cauline leaves linear, grass-like, sheathing the whole stem.

Tall, 6–18 in. Leaves $\frac{1}{4}$–$\frac{1}{2}$ in. broad. Flower large, 2–3 in. long; sepals and petals produced into long filiform points.. .. 1. *P. Banksii.*
Short, stout, 4–10 in. Leaves $\frac{1}{2}$–$\frac{3}{4}$ in. broad. Flower small, $\frac{3}{4}$–$1\frac{1}{4}$ in. long; sepals and petals with short subulate points.. 2. *P. australis.*
Slender, 4–10 in. Leaves $\frac{1}{8}$–$\frac{1}{4}$ in. broad. Flower small, $\frac{1}{4}$–$\frac{3}{4}$ in. long; sepals and petals with short subulate points.. .. 3. *P. graminea.*

** Radical leaves broad, oblong to ovate or orbicular, few or numerous and rosulate. Cauline leaves narrow, often reduced to sheathing bracts.

Slender, 4–12 in. Lower leaves $\frac{1}{2}$–$1\frac{1}{2}$ in., oblong; cauline 2–5, lanceolate, flat. Flower $\frac{3}{4}$–$1\frac{1}{2}$ in., galea not decurved .. 4. *P. micromega.*
Slender, 4–6 in. Cauline leaves 2–3, $1\frac{1}{2}$–2 in. long, oblong-lanceolate, flat, finely reticulate. Flower $1\frac{1}{4}$–$1\frac{1}{2}$ in. long, galea not decurved .. .. 5. *P. areolata.*
Stout or slender, 6–12 in. Lower leaves large, $1\frac{1}{2}$–$3\frac{1}{2}$ in., broadly ovate; cauline of 2–4 sheathing bracts. Flowers $\frac{1}{3}$–$\frac{1}{2}$ in. .. 11. *P. puberula.*

additional PTEROSTYLIS.

P. confertifolia, Allan.

Distribution: North Is. Ruahine range.

see T.N.Z.I. Vol. 56 p. 33. (Cockayne & Allan)

B. Catochilus. *Lower lip reflexed. Basal appendage of lip entire, obtuse.*

Leaves ovate-lanceolate. Flower solitary, large, $\frac{3}{4}$–1 in. long. Lip filiform, clothed with golden-yellow hairs .. .. 12. *P. barbata.*
Leaves ovate. Flowers 2–8, small, $\frac{1}{4}$ in. long; lip oblong, obtuse, glabrous .. .. 13. *P. mutica.*

1. **P. Banksii** *R. Br. ex. A. Cunn. in Bot. Mag.* (1832) t. 3172.—Tall, slender, leafy, grassy, 6–18 in. high. Lower leaves reduced to scarious sheathing scales; cauline numerous, sheathing the whole stem, usually overtopping

10. **CALEANA** R. Br.

Glabrous terrestrial herbs. Root of small rounded tubers on fleshy fibres. Leaf solitary, linear or lanceolate or oblong. Flowers solitary or 2–4 in a terminal raceme; bracts acute. Sepals and petals subequal, all linear; the upper sepal erect, the lateral sepals and petals spreading or deflexed (but the position apparently reversed through the ovary being recurved). Lip uppermost, jointed on to the base of the column or to a projection from it, mobile; claw linear, incurved; lamina ovate or oblong, peltate, undivided, entire, smooth or tuberculate. ** Radical leaves broad, oblong to ovate or orbicular, few or numerous and rosulate. Cauline leaves narrow, often reduced to sheathing bracts.

Slender, 4–12 in. Lower leaves $\frac{1}{2}$–$1\frac{1}{2}$ in., oblong; cauline 2–5, lanceolate, flat. Flower $\frac{3}{4}$–$1\frac{1}{2}$ in., galea not decurved .. 4. *P. micromega.*

Slender, 4–6 in. Cauline leaves 2–3, $1\frac{1}{2}$–2 in. long, oblong-lanceolate, flat, finely reticulate. Flower $1\frac{1}{4}$–$1\frac{1}{2}$ in. long, galea not decurved .. .. 5. *P. areolata.*

Stout or slender, 6–12 in. Lower leaves large, $1\frac{1}{2}$–$3\frac{1}{2}$ in., broadly oblong; cauline few, large, flat. Flower 1–$1\frac{1}{2}$ in., galea much decurved at the tip. .. .. 6. *P. Oliveri.*

Short, stout, 3–6 in. Lower leaves numerous, rosulate, $\frac{3}{4}$–$1\frac{3}{4}$ in. long. Cauline leaves 2–3, sheathing. Flowers large, $\frac{3}{4}$–1 in., strongly decurved from the base .. .. 7. *P. Matthewsii.*

Stout, glabrous or glandular-pubescent, 2–8 in. Lower leaves subrosulate, 1–$1\frac{3}{4}$ in., elliptic-oblong; cauline of 1–2 sheathing bracts. Flowers $\frac{3}{4}$ in.; galea arched but not decurved .. 8. *P. foliata.*

Small, 2–3 in. Lower leaves 2–3, large, $\frac{3}{4}$–2 in., broadly oblong, cauline wanting. Flower $\frac{1}{2}$–$\frac{3}{4}$ in. .. .. 9. *P. venosa.*

Slender, glabrous, 2–8 in. Lower leaves long-petioled; blade $\frac{1}{4}$–$\frac{1}{3}$ in., ovate; cauline narrow, flat. Flower $\frac{1}{2}$–1 in. .. 10. *P. trullifolia.*

Puberulous, 2–6 in. Lower leaves short-petioled; blade small, ovate; cauline of 2–4 sheathing bracts. Flowers $\frac{1}{3}$–$\frac{1}{2}$ in. .. 11. *P. puberula.*

B. Catochilus. *Lower lip reflexed. Basal appendage of lip entire, obtuse.*

Leaves ovate-lanceolate. Flower solitary, large, $\frac{3}{4}$–1 in. long. Lip filiform, clothed with golden-yellow hairs .. .. 12. *P. barbata.*

Leaves ovate. Flowers 2–8, small, $\frac{1}{4}$ in. long; lip oblong, obtuse, glabrous .. .. 13. *P. mutica.*

1. **P. Banksii** *R. Br. ex. A. Cunn. in Bot. Mag.* (1832) t. 3172.—Tall, slender, leafy, grassy, 6–18 in. high. Lower leaves reduced to scarious sheathing scales; cauline numerous, sheathing the whole stem, usually overtopping

P. conjestiglia allan 56: 32 = P. humilis Rogers T.R.S.S. Aust. 1922 See Hatch TNZI 75: 369.

the flower but often shorter than it, 3–14 in. long, $\frac{1}{4}$–$\frac{1}{2}$ in. broad, narrow linear-lanceolate, acuminate, pale-green. Flower solitary, large, 2–3 in. long including the tails to the lateral sepals, green, often streaked with red or reddish-brown. Galea erect at the base and then curved forwards; upper sepal produced into a long caudate often filiform point; petals also caudate-acuminate or shortly filiform, but always much shorter than the upper sepal. Lower lip with the entire part broadly cuneate, the free lobes gradually narrowed into long filiform erect tails 1–2 in. long. Lip narrow linear-oblong, obtuse, its tip slightly exserted; basal appendage curved, repeatedly divided and penicillate at the tip. Column slender, more than $\frac{1}{2}$ the length of the galea, upper lobe of wings with an erect subulate tooth at the outer angle; lower lobe narrow-oblong, obtuse.—*A. Cunn. Precur.* (1836) n. 313; *Raoul Choix* (1846) 41; *Hook. f. Fl. Nov. Zel.* i (1853) 248; *Handb. N.Z. Fl.* (1864) 268; *Cheesem. Man. N.Z. Fl.* (1906) 679; *Ill. N.Z. Fl.* ii (1914) t. 195. P. emarginata *Col. in Trans. N.Z. Inst.* xv (1883) 328. P. patens *Col. l.c.* xviii (1886) 270. P. speciosa *Col. l.c.* xxii (1890) 488. P. auriculata *Col. l.c.* xxii (1890) 489. P. subsimilis *Col. l.c.* xxviii (1896) 611.

North and South Islands, Stewart Island, Chatham Islands: Abundant in shaded places from the North Cape southwards. Sea-level to 4000 ft. October–November.

The most widely spread of the New Zealand species. It varies much in size and degree of robustness, the size of the flower, and in the length of the filiform tails to the sepals and petals, &c. Mr. Colenso has made no less than 5 species based upon what appear to me to be exceedingly slight and inconstant differences. After a careful study of his descriptions and specimens I must confess my inability to distinguish any of them, even as varieties.

2. **P. australis** *Hook. f. Fl. Nov. Zel.* i (1853) 248.—Habit of *P. Banksii* but shorter, 4–10 in. high, rarely more. Leaves shorter and broader, seldom overtopping the flower, $\frac{1}{2}$–$\frac{3}{4}$ in. broad, linear-lanceolate, acute or acuminate. Flower small, $\frac{3}{4}$–$1\frac{1}{4}$ in. long including the points of the sepals. Galea much as in *P. Banksii*, but the upper sepal and petals are not produced into filiform points. Lower lip with the free lobes narrowed into short subulate erect points not exceeding the galea in length. Lip and column as in *P. Banksii.*—*Handb. N.Z. Fl.* (1864) 268; *Cheesem. Man. N.Z. Fl.* (1906) 679.

North and South Islands: In various localities from the Ruahine Mountains to the south of Otago, but not common. Stewart Island, Chatham Islands: Abundant, *Lyall, T. Kirk! Cockayne, H. H. Travers, F. A. D. Cox!* &c. November–January.

No doubt very closely allied to *P. Banksii*, and to some extent connected with it by intermediate forms. But if it be merged with that species, then for the sake of consistency *P. graminea* should also be included, for it occupies just the same position on one side of *P. Banksii* that *P. australis* does on the other. It seems preferable to treat both as distinct though closely related species.

3. **P. graminea** *Hook. f. Fl. Nov. Zel.* i (1853) 248.—Habit of *P. Banksii*, but smaller and much more slender, 4–10 in. high. Leaves overtopping the flower or shorter than it, 1–5 in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, narrow-linear or narrow linear-lanceolate, acute or acuminate. Flower small, $\frac{1}{2}$–$\frac{3}{4}$ in. long including the points of the sepals. Galea as in *P. Banksii*, but the upper sepal and petals, although acuminate, are not produced into filiform points or into very short ones. Lower lip with the free lobes narrowed into

subulate or shortly filiform erect points almost equalling the galea. Lip and column as in *P. Banksii.*—*Handb. N.Z. Fl.* (1864) 268; *Cheesem. Man. N.Z. Fl.* (1906) 680.

Var. **rubricaulis** *H. B. Matthews* MS. *n. var.*—Very close to the type, but stems red, leaves usually 3 only, seldom 4. Flowers larger and broader, sometimes 1¼ in. long. Lateral sepals considerably longer.

North and South Islands, Stewart Island: Not uncommon in shaded places in lowland districts from the North Cape southwards. September–November.

Differs from *P. Banksii* in the smaller size, narrower leaves, and smaller flower with very short tails to the sepals.

4. **P. micromega** *Hook. f. Fl. Nov. Zel.* i (1853) 248.—Slender, glabrous, 4–12 in. high. Lower leaves ½–1½ in. long, ¼–½ in. broad, ovate-oblong to linear-oblong or lanceolate, obtuse or acute, sessile or petiolate; cauline 2–5, smaller and narrower, sessile, flat, sheathing at the base, acute or acuminate. Flower large, solitary, erect, ¾–1½ in. long. Galea erect at the base, then incurved, tip horizontal or nearly so; upper sepal narrow, acuminate; petals slightly shorter, broad, falcate, acuminate. Lower lip with the entire part cuneate, the free lobes very gradually narrowed into long filiform points embracing the galea, often quite 1 in. long. Lip narrow-linear, its tip exserted; basal appendage curved, penicillate. Column about ½ as long as the galea, upper lobe of wing with an erect subulate tooth, lower lobe oblong, obtuse.—*Handb. N.Z. Fl.* (1864) 268; *Cheesem. Man. N.Z. Fl.* (1906) 680. P. polyphylla *Col. in Trans. N.Z. Inst.* xxii (1890) 489.

North Island: Auckland—Swamps near Lake Tongonge, near Kaitaia, *R. H. Matthews!* Coromandel Harbour, *Joliffe* (Handbook); Paeroa Range, near Waiotapu, *K. W. Allison!* Taranaki—Ngaire Swamp, *T. F. C.* Wellington—Swamps near Tongariro, *H. Hill!* Murimotu, *Petrie!* swamps at Wairarapa, *Colenso!* Karioi, *A. Hamilton!* Sea-level to 3000 ft. December–January.

Best known by the slender habit, usually few radical leaves, numerous rather small flat cauline leaves, and large flower projecting outwards but not decurved at the tip.

5. **P. areolata** *Petrie in Trans. N.Z. Inst.* l (1918) 210.—Slender, glabrous, 4–6 in. high. Lower leaves not seen. Cauline leaves 2–3, 1½–2 in. long, ⅓–½ in. broad, oblong-lanceolate or elliptic-lanceolate, acute or subacute, thin, flat, sheathing at the base, finely reticulately veined. Flower rather large, solitary, erect, 1¼–1½ in. long, green streaked with reddish-brown. Galea erect at the base for more than ½ its length, then suddenly curved forwards; upper sepal terminating in a rather long but not filiform tip. Lower lip with the entire portion obcuneate, the free lobes gradually narrowed into long wide-spreading filiform points almost reaching the top of the galea. Column more than ½ as long as the galea. Lip narrow-linear, its tip exserted.

South Island: Marlborough—Base of Shingle Peak, Awatere Valley, alt. 3000 ft., *Cockayne!* Canterbury—Waimakariri Valley, at Bealey, 2500 ft., *T. Kirk!*

This is a somewhat critical species, which can hardly be considered as well established until more material has been obtained. Only 2 flowering specimens have been seen.

6. **P. Oliveri** *Petrie in Trans. N.Z. Inst.* xxvi (1894) 270.—Stout or slender, leafy, glabrous, 6–12 in. high. Lower leaves few, large, 1½–3½ in. long, ¾–1 in. broad, oblong-ovate or elliptic-oblong to oblong-lanceolate,

acute, narrowed into a short broad petiole or almost sessile, thin and membranous, veins reticulated; cauline leaves 2 or 3, almost as long but narrower, lanceolate or oblong-lanceolate, acute or acuminate, flat, spreading, sheathing at the base. Flowers large, solitary or very rarely 2, 1–1½ in. long. Galea bent forwards so that the point often reaches the ovary; upper sepal produced into a long acuminate point; petals much shorter, falcate, acuminate. Lower lip with the entire part broadly cuneate, the free lobes gradually narrowed into long filiform points embracing the galea and sometimes 1½ in. long. Lip narrow-linear, obtuse; basal appendage short, curved, penicillate. Column slender, not ½ the length of the galea; wings with a short upper lobe bearing an erect subulate tooth at the outer angle, lower lobe very long, linear-oblong, obtuse.—*Cheesem. Man. N.Z. Fl.* (1906) 680.

South Island: Nelson—Mount Arthur Plateau, *T. F. C.* Canterbury—Bealey, *T. Kirk!* Waimakariri Glacier, *T. F. C.* Westland—Kelly's Creek, *Petrie!* Otira Gorge, *Cockayne, T. F. C.* 1000–4000 ft. December–January.

Very close to *P. micromega*, but stouter, with much larger radical and cauline leaves, and with the flower very conspicuously decurved.

7. **P. Matthewsii** *Cheesem. in Trans. N.Z. Inst.* xlvii (1915) 46.—Stout, glabrous or sparingly puberulous, 3–5 in. high. Lower leaves 6–8, rosulate at the base of the stem, petiolate, ¾–1¾ in. long, oblong or oblong-ovate, acute or subacute, truncate or almost subcordate at the base, thin and membranous; venation conspicuous, consisting of 2 or 3 parallel longitudinal veins on each side of the midrib, connected by numerous transverse veinlets. Cauline leaves or bracts usually 2, erect and sheathing the greater part of the stem above the leaves, ¾–1¼ in. long, lanceolate or oblong-lanceolate, acute. Flowers solitary, large for the size of the plant, ¾–1 in. long, ½ in. broad, strongly curved outwards and downwards from the base, so that the tip becomes almost horizontal and points to the stem below the ovary. Upper sepal acute or acuminate; petals almost equal in length, falcate, lanceolate, acuminate. Lateral sepals (lower lip) connate to the middle, the free portions gradually narrowed into short filiform points embracing the galea. Lip narrow-ligulate, flat, obtuse; basal appendage short, penicillate at the tip. Column slender; auricles with an acuminate tooth at the tip.

North Island: Mongonui County, crest of ridge leading to Pukemiro Hill, near Kaitaia, *H. B. Matthews!*

No doubt nearly related to *P. foliata*, but easily separated by the more numerous rosulate radical leaves, which are obviously petiolate and truncate or even subcordate at the base, and by the strongly deflexed flowers. The flowers of *P. foliata* are always erect at the base, and although the upper part curves forward it never becomes deflexed to anything like the extent of *P. Matthewsii*. I have had much pleasure in dedicating the plant to its zealous discoverer, who, with his father, the late Mr. R. H. Matthews, has done excellent work in investigating the orchid flora of the extreme northernmost portions of the Dominion.

8. **P. foliata** *Hook. f. Fl. Nov. Zel.* i (1853) 249.—Rather stout, very variable in size, 3–18 in. high; upper part of peduncle, ovary, and occasionally the lateral sepals more or less finely glandular pubescent. Lower leaves 2–5, subrosulate, sessile or shortly petiolate, 1–1¾ in. long, elliptic-oblong to linear-oblong, obtuse or subacute, rather fleshy when fresh, veins conspicuously reticulated when dried; cauline leaves reduced to 1 or 2 large sheathing erect lanceolate bracts ½–1 in. long. Flower solitary, erect, ¾ in.

long. Galea erect at the base, curved forwards at the tip; upper sepal acute or acuminate; petals falcate, obtuse or subacute. Lower lip with the entire part short, broadly cuneate, the free lobes gradually narrowed into short filiform points embracing the galea but not much exceeding it. Lip linear-oblong, flat, obtuse; basal appendage short, curved, penicillate at the tip. Column not $\frac{1}{2}$ the length of the galea, upper lobe of wing with a subulate tooth; lower lobe oblong, obtuse.—*Handb. N.Z. Fl.* (1864) 268; *Cheesem. Man. N.Z. Fl.* (1906) 681; *Ill. N.Z. Fl.* ii (1914) t. 196.

North Island: Hawke's Bay—Lake Tutira, *H. Guthrie-Smith!* Wellington—Ruahine Mountains and Cape Palliser, *Colenso!* Patangata, *Tryon!* Tararua Mountains, *B. C. Aston!* South Island: Marlborough—*T. Kirk!* Canterbury—Ashburton, *H. H. Allan!* Otago—*Buchanan!* Signal Hill, Millburn, Tuapeka, *Petrie!* Sea-level to 2500 ft., usually in *Sphagnum* bogs. December–January.

Differs from *P. micromega* in the stouter habit, larger more reticulate and often decidedly rosulate radical leaves, cauline leaves reduced to sheathing bracts, smaller flowers with shorter points to the lateral sepals, and broader shorter lip. *P. Oliveri* is separated by the same characters, and by the much larger conspicuously decurved flower. According to Dr. Schlechter, *P. foliata* is closely allied to the New Caledonian *P. Bureauviana*, a species with which I am not acquainted.

9. **P. venosa** *Col. in Trans. N.Z. Inst.* xxviii (1896) 610.—Small, perfectly glabrous, 2–3 in. high. Leaves 2 or 3 near the base of the stem, large for the size of the plant, $\frac{3}{4}$–2 in. long, broadly oblong to oblong-ovate or elliptic-oblong, obtuse or subacute, thin and membranous, veins conspicuously reticulated; cauline leaves wanting. Scape short; flower solitary, $\frac{1}{2}$–$\frac{3}{4}$ in. long. Galea erect at the base, sharply curved forwards towards the tip; upper sepal acute or acuminate; petals broadly falcate, acute. Lower lip broadly cuneate, the free lobes narrowed into filiform points exceeding the galea, sometimes recurved at the tips. Lip lanceolate, narrowed to a blunt point, rather thick, grooved, purplish; basal appendage penicillate at the tip. Column barely $\frac{1}{2}$ as long as the galea, upper lobe of wing with an erect subulate point; lower lobe oblong, obtuse.—*Cheesem. Man. N.Z. Fl.* (1906) 681. (?) P. trifolia *Col. l.c.* xxxi (1899) 281.

North Island: Ruahine Mountains, *Olsen!* Mount Holdsworth, Tararua Range, *W. Townson!* South Island: Marlborough—Endeavour Inlet, alt. 3000 ft., *J. H. Macmahon!* Nelson—Mount Frederic, near Westport, *W. Townson!*

This appears to be separated from *P. foliata* by the smaller size and proportionately larger leaves, the short scape, which wants the large sheathing bracts of *P. foliata*, and by the more sharply curved and more acute galea. Although I do not doubt its distinctness as a species, the amount of material examined is small, and much of it is in poor condition. A fresh description of the flower, based on living specimens, is much wanted.

10. **P. trullifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 249.—Stem slender, glabrous, 2–6 in. high, seldom more. Radical leaves often wanting in flowering specimens or 1–4, in flowerless ones more numerous and subrosulate, petiolate; blade $\frac{1}{4}$–$\frac{1}{3}$ in. long, broadly ovate or orbicular-cordate or trowel-shaped, acute or obtuse; petiole as long or longer than the blade. Cauline leaves or bracts 3–5, flat, spreading, $\frac{1}{3}$–1 in. long, lanceolate or linear-lanceolate, acute or acuminate, the lower sometimes broader and petiolate. Flower solitary, $\frac{1}{2}$–1 in. long. Galea erect at the base and then gradually curved forwards; upper sepal lanceolate, acuminate; petals as broad, falcate, acuminate. Lower lip broadly cuneate, the lobes long and filiform, embracing the upper sepal and exceeding it. Lip linear, glabrous, obtuse, its tip exserted; basal appendage linear, much curved, penicillate

at the tip. Column less than ½ the length of the galea; wings with a small triangular upper lobe or tooth; lower lobe oblong, obtuse.—*Handb. N.Z. Fl.* (1864) 269; *Cheesem. Man. N.Z. Fl.* (1906) 682; *Ill. N.Z. Fl.* ii (1914) t. 194B. P. rubella *Col. in Trans. N.Z. Inst.* xviii (1886) 271.

Var. **gracilis** *Cheesem. in Trans. N.Z. Inst.* xlvii (1914) 46.—Taller and more slender than the type, sometimes 10 in. high. Radical leaves usually wanting in flowering specimens, and seldom more than 1 or 2 in barren plants. Cauline leaves narrower. Flowers smaller, ½–⅔ in. long; lateral sepals shorter in proportion.—*Ill. N.Z Fl. l.c.* t. 194B, *flgt-hand figure.*

North Island: Lowland districts from the North Cape to Wellington, apparently rare and local to the south of the East Cape. South Island: Marlborough—Mount Peter, *J. H. Macmahon!* Sea-level to 1500 ft. Var. *gracilis* probably has the range of the type; but I have not seen specimens from the south of the Waikato River.

11. **P. puberula** *Hook. f. Fl. Nov. Zel.* i (1853) 249.—Stem slender, puberulous, especially below, 2–4 in. high. Leaves all radical, crowded in a rosette at the base of the stem, small, shortly petiolate, ⅕–½ in. including the petiole, ovate or ovate-cordate, acute; bracts on the stem above the leaves 2–4, sheathing, erect, lanceolate, acuminate. Flower solitary, erect, ½ in. long. Galea erect, shortly and abruptly incurved towards the tip, the upper sepal acute, the petals as long or rather longer, obtuse. Lateral sepals united for nearly ½ their length into a narrow almost quadrangular lamina, the lobes filiform, erect, separated by a broad truncate sinus which bears a small inflexed tooth in the middle. Lip linear-oblong, obtuse, its tip barely exserted; basal appendage linear, curved, penicillate at the tip. Column about ½ the length of the galea, the wings with a small erect triangular upper lobe or tooth, the lower lobe linear-oblong, obtuse.—*Handb. N.Z. Fl.* (1864) 269; *Cheesem. Man. N.Z. Fl.* (1906) 682.

North Island: Auckland—Clay hills from the Kaipara Harbour southwards to the Thames and Middle Waikato, not common. South Island: Nelson—Vicinity of Westport, *W. Townson!* September–October.

A distinct little plant, well marked by the puberulous stems, small rosulate leaves, the short blunt curved tip to the galea, and comparatively short filiform points to the lateral sepals.

12. **P. barbata** *Lindl. Bot. Regist.* xxv (1839) App. 53.—Stem stout or slender, glabrous, 4–8 in. high. Leaves radical, crowded at the base of the stem, often rosulate, erect, sessile, ¼–¾ in. long, ovate-lanceolate or lanceolate, acute or acuminate. Stem above the leaves with 2–5 large loosely sheathing erect empty bracts. Flower solitary, ¾–1 in. long. Galea erect, incurved at the tip, oblong; upper sepal and petals both produced into short subulate points, the latter very narrow. Lower lip linear, deflexed, 2-lobed about half-way down, the lobes very narrow, acute or obtuse. Lip ½–¾ in. long, filiform, terete, exserted, pendulous, fringed with long golden yellow hairs and terminated by a large capitate or irregularly lobed purple gland; appendix very short, curved, penicillate at the tip. Column slender, erect; the wings each with a long erect subulate tooth on the front angle, the lower lobe narrow, ciliate.—*Benth. Fl. Austral.* vi (1873) 362; *Cheesem. Man. N.Z. Fl.* (1906) 683. P. squamata *Hook. f. Fl. Nov. Zel.* i (1853) 249; *Fl. Tasm.* ii (1860) 20, t. 116; *Handb. N.Z. Fl.* (1864) 269 (*not of R. Br.*).

North Island: Auckland—Exact locality not stated, *Sinclair!* near Kaitaia, *R. H. Matthews!* Cowes, Waiheke Island, *J. H. Harvey!* Lower Thames Valley, from Kopu and Puriri to Kerikeri, *Adams! T. F. C.;* between Mercer and Miranda,

T. F. C.; Tirau and other places in the Upper Thames Valley, *T. F. C.*; Kaitoke, Tararua Mountains, *B. C. Aston!* Day's Bay, Wellington Harbour, *E. H. Atkinson!* Sea-level to 1000 ft. October–November.

A very remarkable little plant, at once recognized by the filiform exserted lip plumose with bright-yellow hairs. It is a common Tasmanian plant, and is also found in South Australia, Victoria, and New South Wales.

13. **P. mutica** *R. Br. Prodr.* (1810) 328.—Rather stout, 2–5 in. high. Leaves radical, forming a rosette at the base of the stem, sometimes withering at the flowering season, shortly petiolate, $\frac{1}{3}$–$\frac{3}{4}$ in. long, ovate, acute, veins reticulated. Stem with 2–5 large sheathing bracts above the leaves. Raceme 2–8-flowered; flowers small, about $\frac{1}{4}$ in. long, greenish-brown. Galea very broad, much incurved, obtuse or subacute at the tip. Lower lip small, reflexed, concave, nearly orbicular when spread out, 2-lobed almost to the middle. Lip on a very short flat claw, lamina broadly oblong, obtuse; appendage broad at the base, short and thick, entire, rounded or emarginate at the tip. Column erect; wings broad, the lower lobe or auricle broad, obtuse.—*Hook. f. Fl. Tasm.* ii (1860) 21, t. 117A; *Benth. Fl. Austral.* vi (1873) 362; *Fitzgerald Austral. Orch.* i (1877) pt. 2; *Cheesem. in Trans. N.Z. Inst.* xv (1883) 300; *Man. N.Z. Fl.* (1906) 683. P. tristis *Col. in Trans. N.Z. Inst.* xviii (1886) 271.

North Island: Hawke's Bay—Waipawa River, *H. Hill!* South Island: Canterbury—Lake Lyndon and Lake Grassmere, *J. D. Enys!* Lake Heron, *Cockayne;* Ashburton, *H. H. Allan!* Cass River, *Cockayne* and *Foweraker;* Mount Arrowsmith, *Cockayne* and *R. M. Laing.* Otago—Lee Stream, *Sydney Fulton!* Horse Range, Naseby, St. Bathan's, Cambrian's, *Petrie!* Sea-level to 2500 ft. November–January.

An abundant Australian plant, ranging from Queensland to Tasmania.

12. **ACIANTHUS** R. Br.

Small tender terrestrial herbs. Root of rounded tubers at the end of long fleshy fibres. Leaf solitary, sessile, cordate. Flowers few or many in a raceme, rarely solitary; bracts usually small. Upper sepal erect or curved over the column, concave, rather narrow, acute or acuminate; lateral sepals narrower, often almost filiform, erect or spreading. Petals shorter than the sepals, subulate-lanceolate. Lip equalling the petals, sessile or nearly so, undivided, base with 2 adnate calli, disc smooth or papillose. Column elongated, erect or incurved, semiterete or winged; stigma cup-shaped, placed under the rostellum. Anther terminal, erect, 2-celled; pollinia 2 or 4 in each cell, granular.

A genus comprising 7 species: 4 in Australia, 2 in New Caledonia, and 1 in New Zealand.

See Hooker 7:5: 269.

1. **A. Sinclairii** *Hook. f. Fl. Nov. Zel.* i (1853) 245.—Stems slender, sometimes almost filiform, 1–6 in. high. Leaf near the base or almost half-way up the stem, sessile, $\frac{1}{2}$–$1\frac{1}{2}$ in. long, broadly ovate-cordate, acute or acuminate, deeply bilobed at the base, membranous, often purple beneath, veins reticulated. Flowers 2–12, shortly pedicelled, $\frac{1}{4}$ in. diam., green; bracts ovate, acute, the lowest sometimes foliaceous. Upper sepal ovate-oblong, aristate, 3-nerved; lateral sepals and petals subulate-lanceolate, acuminate. Lip horizontal or deflexed, ovate-lanceolate, concave, base with 2 large calli, tip thickened and studded with minute fleshy

papillae. Column arched over the lip, much thickened and expanded towards the tip. Pollinia 2 in each anther-cell, deeply bilobed.—*Handb. N.Z. Fl.* (1864) 264; *Cheesem. Man. N.Z. Fl.* (1906) 684.

KERMADEC ISLANDS, NORTH ISLAND: Abundant in lowland districts throughout. SOUTH ISLAND: Marlborough—Pelorus Sound, *J. H. Macmahon!* Nelson—Dun Mountain, *T. Kirk!* near Westport, *W. Townson!* CHATHAM ISLANDS: Abundant, *F. A. D. Cox! Miss Seddon!* Sea-level to 2500 ft. May–August.

For an account of the fertilization, see a paper by myself in Trans. N.Z. Inst. vii (1875) 349.

13. **CYRTOSTYLIS** R. Br.

Small delicate terrestrial herbs. Root of rounded tubers on long fleshy fibres. Leaf solitary, sessile, oblong to orbicular. Flowers few in a terminal raceme, often reduced to one; bracts small. Upper sepal linear or linear-lanceolate, erect or incurved, concave; lateral sepals and petals narrow-linear, spreading or deflexed. Lip horizontally spreading from the base of the column, undivided, oblong, flat, entire; base with 2 calli, produced into raised lines for some distance along the lamina. Column elongated, incurved, winged on each side towards the summit; stigma cup-shaped, placed just under the rostellum. Anther terminal, erect, 2-celled; pollinia 2 in each cell, falcate or lobed.

A genus of 2 closely allied species, one found in New Zealand, the other in Australia.

1. **C. oblonga** *Hook. f. Fl. Nov. Zel.* i (1853) 246.—Stems very slender, glabrous, 1–4 in. high. Leaf towards the base of the stem, sessile, spreading, ½–1½ in. long, oblong or oblong-ovate, obtuse or subacute, cordate or rounded at the base, thin and membranous, flat, obscurely 3–5-nerved. Flowers solitary or in a 2–5-flowered raceme, greenish, ⅓ in. diam.; bracts small, ovate-lanceolate. Upper sepal narrow linear-obovate, erect; lateral sepals and petals narrow-linear, acute, spreading or deflexed. Lip as long as the sepals, linear-oblong, obtuse. Column slender, about ⅔ the length of the upper sepal. Pollinia 2 in each anther-cell, oblong-falcate.—*Handb. N.Z. Fl.* (1864) 264; *Cheesem. Man. N.Z. Fl.* (1906) 685.

Var. **rotundifolia.**—Altogether like the type, but the leaf is orbicular-cordate, ½–1½ in. diam.—C. rotundifolia *Hook. f. Fl. Nov. Zel.* i (1853) 246; *Handb. N.Z. Fl.* (1864) 264. C. macrophylla *Hook. f. Fl. Nov. Zel.* i (1853) 246.

NORTH ISLAND: Not uncommon from the North Cape southwards. SOUTH ISLAND: Marlborough—Pelorus Sound, *J. Rutland, J. H. Macmahon!* Nelson—Buller Valley, *T. F. C.* Canterbury—Banks Peninsula, *J. B. Armstrong;* Broken River, *J. D. Enys! T. F. C.* Sea-level to 2500 ft. August–October.

I have been compelled to sink *C. rotundifolia* as a species. It differs in no respect except in the width of the leaf, and in several localities I have observed the two forms growing intermixed and gradually passing into each other.

14. **CALOCHILUS** R. Br.

Glabrous terrestrial herbs. Root of oblong tubers. Leaves 1 or rarely 2 near the base of the stem, narrow-linear; usually there are 1 or 2 foliaceous sheathing bracts higher up. Flowers few in a terminal raceme, rather large, handsome; pedicels short; lower bract usually exceeding the ovary. Sepals almost equal, free; upper erect, broad, concave; lateral spreading. Petals smaller, broadly falcate. Lip as long or longer than the sepals, sessile, spreading or pendulous, undivided, the margins and whole surface

except the narrow flexuous tip densely fringed with long hairs. Column short, broadly winged; stigma broad, placed under the erect rostellum. Anther large, terminal, erect or incumbent, obtuse or pointed, 2-celled; pollinia granular.

A genus of 3 very closely related species, all natives of Australia, 2 of them extending to New Zealand as well.

Anther long, rostrate. Column-wing with a gland on each side near the base just within the front margin .. .. 1. *C. campestris.*
Anther short, obtuse. Column-wing without any gland, but 2 small erect lamellae on each side of the base of the lip .. 2. *C. paludosus.*

1. **C. campestris** *R. Br. Prodr.* (1810) 320.—Stem stout, 6–18 in. high. Leaf usually solitary, rarely 2, much shorter than the stem, narrow-linear, thick, channelled; cauline leaves or bracts 1 or 2, sheathing. Flowers 2–8, greenish-purple; pedicels ½–1 in. long; bracts acuminate. Upper sepal ⅓–½ in. long, broadly ovate, acute, concave; lateral narrower. Petals shorter, broadly oblong, falcate, veined. Lip ½–¾ in. long; margins and upper surface except the slender flexuous tip covered with long reddish-purple hairs or fimbriae, which are longest on the upper part of the lip, and shortest near the base, where they are reduced to clavate calli; usually there is a narrow strip across the very base of the lip which is smooth and bare. Column-wings dilated in front and produced into a rounded lobe on each side, on the inner face of which is a conspicuous gland. Anther long, triangular, rostrate.—*Benth. Fl. Austral.* vi (1873) 315; *Fitzgerald Austral. Orch.* i (1877) pt. 4; *T. Kirk in Trans. N.Z. Inst.* xxiv (1892) 427; *Cheesem. Man. N.Z. Fl.* (1906) 686.

North Island: Auckland—Rotorua, *Spencer! Petrie!* Paeroa Range, near Waiotapu, *K. W. Allison!* November–December.

This doubtless has as wide a range as the following species, but so far I have seen no specimens except from Rotorua. These exactly match the plate in Fitzgerald's Australian Orchids, with the exception that the fimbriae on the lip never show any trace of blue, but are always red.

2. **C. paludosus** *R. Br. Prodr.* (1810) 320.—Very similar in habit and appearance to *C. campestris*, but usually (though not always) more slender, with a rather longer and narrower leaf. Flowers seldom more than 4. Sepals and petals much as in *C. campestris*. Lip longer, the surface and margins with long red fimbriae, the linear bare tip longer, and the base with a thin longitudinal raised plate on each side. Column-wing dilated in front and produced into a rounded lobe on each side, not furnished with a gland on the inner face. Anther short, as broad as long, obtuse, neither acuminate nor rostrate.—*Benth. Fl. Austral.* vi (1873) 316; *Fitzgerald Austral. Orch.* i (1877) pt. 4; *Buch. in Trans. N.Z. Inst.* xv (1883) 240; *Cheesem. Man. N.Z. Fl.* (1906) 686.

North Island: Auckland—Kaitaia, *R. H. Matthews!* Aponga (near Whangarei), *A. Thompson!* Rotorua, *Petrie!* South Island: Nelson—Vicinity of Collingwood, *H. H. Travers!* near Westport, *W. Townson!*

15. **LYPERANTHUS** R. Br.

Terrestrial herbs, often black when dry. Stems rather stout. Leaves 1–3, sheathing at the base, broad or narrow. Flowers in a terminal raceme or spike, sometimes solitary; bracts large, sheathing. Upper sepal erect, incurved, broad, concave; lateral narrow, spreading or deflexed. Petals

Pterostylis californica var. parcelata Rogers 1925 T.N.Z.I. 56:18.

similar to the lateral sepals. Lip shorter than the sepals, with a broad erect claw sometimes dilated into small lateral lobes; lamina or middle lobe ovate or lanceolate, entire; disc with ridges or small calli. Column erect or incurved, not winged; stigma placed under the rostellum. Anther terminal, erect, 2-celled; pollinia 4, narrow, subterete, granular.

A somewhat ill-defined genus of 6 species, 4 of which are found in Australia, 1 in New Caledonia, and the remaining 1 in New Zealand.

1. **L. antarcticus** *Hook. f. Fl. Antarct.* ii (1847) 544.—Stems rather stout, 3–8 in. high. Leaves 1–3, sheathing at the base, 1–2½ in. long, the upper smaller, lanceolate or oblong-lanceolate, acute, rather coriaceous; veins numerous, parallel. Flowers 1–3, greenish, horizontal or nearly so, ⅓–½ in. long; bracts large, cucullate, sheathing, ½–¾ in. long. Upper sepal large, broad, curved over the column, hooded, acute; lateral sepals and petals linear-subulate, acute. Lip with a very short claw; lamina ovate-oblong, obtuse or subacute, margins thick, disc with 5 or 6 slender longitudinal lamellae. Column short, stout, curved.—*Handb. N.Z. Fl.* (1864) 270; *Cheesem. Man. N.Z. Fl.* (1906) 687; *Ill. N.Z. Fl.* ii (1914) t. 197.

North Island: Tararua Mountains, *Petrie, B. C. Aston!* South Island: Subalpine localities from Collingwood and the Spenser Mountains southwards, but not common. Stewart Island: *T. Kirk!* Auckland Islands: *Le Guillou, Bolton, T. Kirk!* 2500 ft. to 4000 ft., descending to sea-level in Stewart Island and the Auckland Islands. December–February.

The upper sepal is much broader and more hooded than in any other species of the genus, the sepals and petals are less spreading, and the column shorter and broader.

16. **CALADENIA** R. Br.

Slender terrestrial herbs, usually more or less pilose or villous, rarely glabrous. Root of small rounded tubers terminating fleshy fibres. Leaf solitary from near the base of the stem, linear or lanceolate, more rarely broader and oblong-lanceolate or oblong. Flowers on an erect slender scape, solitary or in few-flowered racemes; bracts small. Upper sepal erect or incurved, narrow, concave; lateral flat, spreading, or rarely all alike and spreading. Petals narrow, erect or spreading. Lip clawed on to the base of the column, undivided or 3-lobed, the lateral lobes when present erect, the middle lobe spreading or reflexed, the margins often toothed or fimbriate, the disc usually studded with linear or clavate sessile or stipitate calli. Column rather long, erect or incurved, more or less 2-winged above; stigma broad, prominent. Anther erect, terminal, 2-celled; pollinia granular.

About 40 species are known, all confined to Australia, except 1 in Malaya, another in New Caledonia, and the 4 following, which are endemic in New Zealand.

Slender, 3–10 in. high. Leaf solitary, linear, $\frac{1}{15}$–$\frac{1}{8}$ in. broad. Petals and sepals linear, obtuse. Flower ¼–⅓ in. diam. Lip 3-lobed	1 *C. minor.*
Slender, 2–4 in. high. Leaf solitary, linear, $\frac{1}{20}$ in. broad. Flower ⅕ in. diam. Petals and sepals linear, acuminate. Lip 3-lobed	2. *C. exigua.*
Rather stout. Leaf solitary, linear, ⅛–¼ in. broad. Flower ½–1 in. diam. Lip 3-lobed	3. *C. Lyallii.*
Rather stout. Leaves 2, oblong or lanceolate. Flower ¾ in. diam. Lip undivided	4. *C. bifolia.*

1. **C. minor** *Hook. f. Fl. Nov. Zel.* i (1853) 247, t. 56B.—Stems very slender, 3–10 in. high, rarely more, glandular-pilose with spreading hairs. Leaf from near the base of the stem and always shorter than it, 1–8 in. long,

See Hatch T.R.S. N.Z. 1945: 368.

$\frac{1}{16}$–$\frac{1}{8}$ in. broad, very narrow-linear, flat, striate, ciliate or pilose. Flower solitary or rarely 2, pink, about $\frac{1}{3}$ in. diam. Sepals subequal, linear or linear-oblong, obtuse or subacute; upper sepal erect; lateral spreading or deflexed. Petals similar to the sepals, spreading. Lip shorter than the sepals, broad, 3-lobed; lateral lobes large, oblong, obtuse, erect, usually marked with transverse purplish bands; middle lobe lanceolate-deltoid, acuminate, reflexed, margins fringed with linear calli; disc with 2 continuous rows of bright-yellow stipitate calli. Column elongate, as long as the lip, incurved, broadly winged. Anther apiculate.—*Handb. N.Z. Fl.* (1864) 267; *Cheesem. Man. N.Z. Fl.* (1906) 688. C. variegata *Col. in Trans. N.Z. Inst.* xvii (1885) 248.

North and South Islands: From the North Cape to Otago, not uncommon. Sea-level to 2000 ft. September–December.

C. carnea var exigua (Cheesem.) Rupp. Proc. L.S.N.S. W. 69: 174

2. **C. exigua** *Cheesem. in Trans. N.Z. Inst.* xlv (1913) 96.—Closely allied to *C. minor*, but stems shorter and more slender and wiry, 2–5 in. high, sparingly glandular-pilose. Leaf solitary from the base of the stem, small, very narrow linear, $\frac{3}{4}$–$2\frac{1}{2}$ in. long, very sparingly pilose or almost glabrate. Flowers seldom more than one; sepals and petals subequal, all narrow-lanceolate and acuminate, upper sepal erect, the rest spreading or deflexed. Lip broad, 3-lobed; disc with two continuous rows of bright-yellow stipitate glands as in *C. minor;* intermediate lobe with only one marginal stipitate gland on each side; lateral lobes with transverse purplish bands. —C. minor *var.* exigua *Cheesem. Man. N.Z. Fl.* (1906) 688.

North Island: Auckland—*Leptospermum* scrub near Kaitaia, Mongonui County, *R. H. Matthews* and *H. B. Matthews!* Cowes, Waiheke Island, *J. H. Harvey!* September.

In the first edition of this work I treated this as a variety of *C. minor*, to which it is certainly closely allied. Since then Mr. H. B. Matthews has supplied me with an extensive series of fresh specimens, proving that the differences are constant and of more importance than I previously supposed. I now willingly accept it as a distinct species, differing from *C. minor* in its much smaller size and more slender habit; in the smaller flowers; in the sepals and petals being narrow-lanceolate and acuminate, instead of linear and obtuse as in *C. minor;* and in the middle lobe of the lip having only one stipitate gland on each side, whereas *C. minor* has several.

3. **C. Lyallii** *Hook. f. Fl. Nov. Zel.* i (1853) 247.—Rather stout, 4–12 in. high, pilose with long soft hairs. Leaf from near the base of the stem and much shorter than it, $\frac{1}{8}$–$\frac{1}{4}$ in. broad, narrow-linear, rather thick, channelled, sparingly pilose on the margins and under-surface. Scape stout, with a sheathing bract about the middle, 1–2-flowered. Flower large, $\frac{1}{2}$–1 in. diam. Upper sepal $\frac{1}{3}$–$\frac{1}{2}$ in. long, obovate-oblong, erect or incurved, concave; lateral elliptic-oblong. Petals similar to the lateral sepals. Lip about $\frac{1}{2}$ as long as the lateral sepals, 3-lobed; lateral lobes broad, jagged at the tip, often banded with purple; middle lobe small, recurved; disc with 4 rows of stipitate calli. Column rather long, broadly winged, incurved; anther shortly apiculate.—*Handb. N.Z. Fl.* (1864) 267; *Cheesem. Man. N.Z. Fl.* (1906) 688.

South Island, Stewart Island, Auckland Islands.—Not uncommon in subalpine localities. Usually from 2500 to 5000 ft., but descends to sea-level in the Auckland Islands. December–January.

A handsome little plant, much more robust than *C. minor*, and with much larger flowers.

Aporostylis bifolia (Hook.f.) Rupp & Hatch
P.h.s.N.S.W. 70: 60.
See also Hatch TN.Z1. 77: 226.

4. **C. bifolia** *Hook. f. Fl. Nov. Zel.* i (1853) 247.—Stout or slender, glandular-pubescent, 3–9 in. high. Leaves two together towards the base of the stem, spreading, 1–2½ in. long, variable in shape, one usually much broader than the other, ovate or oblong to ovate-lanceolate or lanceolate, acute, sparingly glandular-pubescent, margins ciliate. Scape 1-flowered, with a sheathing bract a little distance below the flower. Flower white with a tinge of pink, nearly 1 in. diam. when fully expanded. Upper sepal narrow-oblong, obtuse, erect, concave; lateral spreading, linear-lanceolate. Petals shorter and narrower. Lip sessile by a narrow base, spreading, orbicular-obovate, rounded at the tip, undivided, margin entire; disc with two almost continuous lines of yellow calli extending from the middle to the base. Column elongate, incurved, 2-winged, wings not produced behind the anther.—*Handb. N.Z. Fl.* (1864) 267; *Cheesem. Man. N.Z. Fl.* (1906) 689; *Ill. N.Z. Fl.* ii (1914) t. 197B. C. macrophylla *Col. in Trans. N.Z. Inst.* xxvii (1895) 396. Chiloglottis Traversii *F. Muell. Veg. Chath. Is.* (1864) 51.

North and South Islands, Stewart Island, Chatham Islands, Auckland Islands: Not uncommon in upland districts from Lake Taupo and Mount Egmont southwards. Ascends to 4500 ft., descends to sea-level in the extreme south and in the outlying islands. December–January.

A curious plant, the genus of which is doubtful. It was referred to *Chiloglottis* by Mueller, and certainly is allied to it in habit, but it wants the essential character of the wings of the column produced into 2 lobes behind the anther. On the whole I think it is best retained in *Caladenia.*

Hatch T.R.S.N.Z. 77: 228.

17. CHILOGLOTTIS R. Br. 1810 – 323.

Terrestrial herbs, with small underground tubers. Leaves 2, radical or nearly so, oblong or linear-oblong. Scape 1-flowered, with a solitary bract below the flower. Upper sepal erect, incurved, concave, narrowed at the base; lateral narrow-linear or terete, spreading or reflexed. Petals lanceolate, falcate. Lip attached to the base of the column by a short or long claw, ovate or obovate, undivided; disc with variously arranged calli. Column elongated, incurved, winged; wings produced at the top into 2 erect lobes often equalling the anther. Stigma placed just under the rostellum. Anther terminal, erect, 2-celled; pollinia 4, granular.

A small genus of 7 species, 6 of which are natives of Australia, one of them extending to New Zealand, the remaining one confined to New Zealand. The genus differs from *Caladenia* principally in the 2-leaved stem and in the wing of the column extending behind the anther. *Caladenia bifolia* has the habit of *Chiloglottis,* but the column-wing is that of *Caladenia,* in which genus I have retained it.

Stout, upper sepal broad ovate-lanceolate; lateral sepals and petals erect. Lip very shortly clawed, trowel-shaped .. .. 1. *C. cornuta.*
Slender. Upper sepal linear-spathulate. Petals deflexed. Lip with a very long narrow claw, lamina rhomboid .. .. 2. *C. formicifera.*

1. **C. cornuta** *Hook. f. Fl. Antarct.* i (1844) 69.—Usually rather stout, perfectly glabrous, 2–5 in. high. Leaves 2, close together, petiolate, spreading, 1–3 in. long, ½–1 in. broad, oblong or linear-oblong or oblong-lanceolate, acute or subacute, flat, rather fleshy when fresh; veins parallel, connected by transverse veinlets. Scape very short at first, but lengthening as the flower withers and sometimes 4–8 in. long in fruit, 1-flowered or very rarely 2-flowered; bract sheathing. Flower about ½ in. diam., green, sometimes spotted with purple. Upper sepal broadly ovate-lanceolate, acuminate, erect. Lateral sepals placed in front of the

lip, linear-lanceolate. Petals ovate-lanceolate, acuminate, erect. Lip triangular-cordate or trowel-shaped, acute, concave; disc with 3 large stalked rounded calli near the base, 2 linear ones on each side higher up, and 3 smaller rounded ones between them. Column curved forwards, winged; the wings expanded above and produced upwards into 2 lobes exceeding the anther.—*Handb. N.Z. Fl.* (1864) 269; *Cheesem. Man. N.Z. Fl.* (1906) 690; *Ill. N.Z. Fl.* ii (1914) t. 198A.

NORTH AND SOUTH ISLANDS, CHATHAM ISLANDS, STEWART ISLAND, ANTIPODES ISLAND, AUCKLAND AND CAMPBELL ISLANDS: Moist shaded places from Kaitaia and Mangonui southwards, not common. Sea-level to 3000 ft. October–December.

As a rule, the calli on the labellum agree with the description given above; but occasionally the number is reduced to 6, and I have seen as many as 12. The flowers are sometimes nearly altogether purple.

2. **C. formicifera** *Fitzgerald Austral. Orch.* i (1877) pt. 3.—Slender, delicate, 2–3 in. high. Leaves 2, close together, sessile, spreading, 1–2 in. long, linear-oblong or oblong-lanceolate, obtuse, thin and membranous, margins often undulate when fresh; veins parallel, connected by transverse veinlets. Scape 2–3 in. high, 1-flowered; bract near the top, sheathing. Flower about ½ in. long. Upper sepal linear-spathulate, erect, acuminate; lateral about the same length, linear, acuminate. Petals linear-lanceolate, abruptly deflexed, about as long as the sepals. Lip horizontal or ascending, contracted below into a long and narrow claw, above suddenly expanded into a short and broad spoon-shaped or rhomboid lamina, the tip of which is usually reflexed; disc with numerous calli, the largest of which is placed at the base, and projects from it, with a kind of double head, towards the column; in front of this is a large flat heart-shaped gland, and rows of smaller calli reach the apex of the lip. Column arched forward, broadly winged.—*Cheesem. in Trans. N.Z. Inst.* xxxiii (1901) 312; *Man. N.Z. Fl.* (1906) 690.

NORTH ISLAND: Auckland—Kaitaia (Mongonui County), *R. H. Matthews!* September–October.

A very remarkable little plant, previously known only from eastern Australia. Mr. Matthews's specimens agree in all respects with Mr. Fitzgerald's beautiful plate. Very rare and local, and up to the present time very few specimens have been found.

18. **ADENOCHILUS** Hook. f.

Slender terrestrial herbs. Leaf solitary, placed near the middle of the stem, ovate. Peduncle slender, 1-flowered, with 1 or 2 sheathing bracts between the flower and the leaf, the upper of which sometimes bears in its axil the minute rudiment of a second flower. Flower small. Upper sepal erect, incurved, concave or almost galeate; lateral lanceolate, placed under the lip. Petals linear-lanceolate, almost equalling the sepals. Lip shortly clawed on to the base of the column, 3-lobed; lateral lobes large, erect; middle lobe smaller, caudate, reflexed; disc and middle lobe with several rows of small stalked calli. Column slender, curved, winged; wings produced upwards into 2 toothed lobes. Stigma prominent, placed just under the rostellum. Anther terminal, erect, 2-celled; pollinia 4 in each cell, granular.

The genus is limited to two species: one endemic in New Zealand, the other (*A. Nortoni* Fitzgerald) in Australia. It is closely allied to both *Caladenia* and *Chiloglottis*, differing from the former in the wing of the column extending behind the anther, and from the latter in the solitary leaf and glandular-pubescent perianth.

1. **A. gracilis** *Hook. f. Fl. Nov. Zel.* i (1853) 246, t. 56A.—Stem slender, glabrous, 5–10 in. high. Leaf sessile half-way up the stem, ½–1 in. long, ovate or ovate-oblong, acute, membranous, veins reticulated. Flower about ½ in. diam., more or less finely glandular-pubescent. Ovary narrow, cylindrical, ½–¾ in. long. Upper sepal adnate to the back of the column towards the base, acuminate; lateral sepals and petals subsimilar, erect, acuminate. Lip much shorter than the sepals and petals and almost concealed by them; middle lobe much smaller than the lateral, caudate, reflexed; calli numerous, stipitate, yellow. Column broadly winged for its whole length, wings produced upwards behind the anther into two broad toothed lobes.—*Handb. N.Z. Fl.* (1864) 265; *Cheesem. Man. N.Z. Fl.* (1906) 691.

North Island: Forests between the Thames and Mercury Bay, *T. Kirk!* forests near the summit of Mount Kakaramea, Taupo, *T. F. C.;* between Ohakune and Mount Ruapehu, *E. Phillips Turner!* near Lake Waikaremoana, *Colenso.* South Island: Nelson—Near Foxhill, *P. Lawson!* Buller Valley, *T. F. C.;* Mount Owen, *W. Townson!* Otago—Mount Maungatua, forests to the west of Lake Te Anau, *Petrie!* near Lake Hauroto, *Thomson!* 500–2500 ft. November–January.

19. **TOWNSONIA** Cheesem. 1906.

A small slender terrestrial herb. Root of creeping fleshy caudicles thickened here and there into small tubers. Radical leaves 1–3 from the caudicles, rarely at the base of the flowering-stem, petiolate, ovate-orbicular. Cauline leaf or empty bract solitary half-way up the stem, sessile, ovate, acute, often much reduced in size. Flowers 1 or 2, small; perianth horizontal or deflexed. Upper sepal much incurved, broad, concave, almost galeate; lateral placed in front of the lip, lanceolate, margins involute. Petals minute, erect. Lip clawed on to the base of the column; lamina erect, undivided, broadly ovate-rhomboid, subcordate at the base, entire, margins involute and clasping the column towards the base; disc smooth, without calli or ridges, or with an obscure thickening on each side near the base. Column rather shorter than the lip, erect, broadly and equally winged from the base; wings not continued upwards behind the anther. Stigma prominent, placed just under the small rostellum. Anther terminal, erect, 2-celled; pollinia free, granular. Hatch T.R.S.N.Z. 77: 227.

A very curious little plant. It has the habit of *Adenochilus*, but differs in the smooth undivided lip, minute petals, and in the column-wings not being produced upwards behind the anther. The smooth undivided lip also separates it from *Chiloglottis, Caladenia, Burnettia,* and other allied genera. The genus has been studied in detail by Dr. Schlechter, who has published his results in a paper entitled "Die Gattung *Townsonia*" (Fedde, Repertorium, ix (1911) 249). He considers that its nearest ally is *Acianthus*. He is further of opinion that the Tasmanian *Acianthus viridis* Hook. f. is a true *Townsonia*, and should be transferred to that genus. At the same time he admits that *Townsonia* differs in the broadly winged column, a character not found in *Acianthus* or allied genera. *Townsonia* is dedicated to its discoverer, Mr. W. Townson, late of Westport, but now of Thames, who is well known from his successful botanical exploration of the north-western portion of the South Island.

Ruppia Vict. Nat. 50: 18. 1933.

T. viridis (Hook. f.) Schltr. Fedde Report. 1911. 9: 249.

1. **T. deflexa** *Cheesem. Man. N.Z. Fl.* (1906) 692.—Very slender, 3–6 in. high. Radical leaves on slender petioles ½–1½ in. long; blade ¼–½ in., broadly oblong or orbicular-ovate, obtuse or apiculate, rounded or subcordate at the base, thin and membranous, veins reticulated. Cauline leaf ovate, acute, often very small and scale-like. Flowers small, ⅙–¼ in. long, greenish.—*Ill. N.Z. Fl.* ii (1914) t. 198B.

Acianthus viridis (Hook. f.) Fl. Tasm. 1860. 2: 372.

South Island: Nelson—Vicinity of Westport, *W. Townson!* Otago—Resolution Island, Dusky Sound, *W. A. Thomson!* November–December.

See Rupp. Bot. U.S. Mus. 1928. 53: 550–558 re Corybas (C. cheesemanii C. orbiculata R.)

20. CORYSANTHES R. Br.

Dwarf very delicate succulent terrestrial herbs. Root of small rounded tubers on fleshy caudicles. Leaf solitary, ovate-cordate or orbicular or reniform. Flower solitary, large for the size of the plant, at first almost sessile on the leaf, but peduncle elongating considerably in fruit. Upper sepal large, erect and incurved, helmet-shaped; lateral free, small and linear, or long and filiform. Petals similar to the lateral sepals but smaller, sometimes wanting. Lip large, the lower portion tubular, the margins meeting behind the column and enclosing it; base with a rounded auricle on each side of the column or with a hollow conical spur; upper part truncate or expanded into a broad abruptly reflexed limb; margins entire or denticulate or fimbriate. Column short, straight, 2-winged at the top; stigma broad, placed just under the rostellum. Anther large, terminal, erect, 2-celled; pollinia 4, powdery, free.

A very curious genus of about 20 species, found in Malaya, Australia, and New Zealand, the species of each country being endemic.

A. Lip produced downwards into 2 conical spurs at the base. Lateral sepals and petals minute.

Leaf $\frac{1}{4}$–$\frac{1}{2}$ in., sessile, ovate-cordate .. .. 1. *C. Cheesemanii.*

B. Lip with 2 rounded orifices at the base. Lateral sepals and petals filiform, longer than the lip (except in C. Carsei *and* Matthewsii).

Leaf $\frac{1}{4}$–$\frac{1}{2}$ in., ovate-cordate. Lateral sepals and petals small. Lip produced into a projecting lamina, not truncate .. .. 2. *C. Carsei.*

Leaf $\frac{1}{2}$–1 in., sessile, ovate- or orbicular-cordate. Lateral sepals and petals about $\frac{1}{2}$ as long as the lip. Lip truncate, entire or minutely denticulate .. .. 3. *C. Matthewsii.*

Leaf $\frac{3}{4}$–1$\frac{1}{2}$ in., sessile, ovate-oblong, rounded or cordate at the base. Lip truncate, coarsely toothed or fimbriate .. .. .. 4. *C. oblonga.*

Leaf $\frac{1}{2}$–2 in., sessile, oblong-ovate, acuminate. Upper sepal acuminate. Lip bent forwards and downwards, acuminate .. 5. *C. rivularis.*

Leaf $\frac{1}{2}$–1$\frac{1}{4}$ in., sessile or shortly petiolate, broadly oblong or orbicular, apiculate. Upper sepal acute. Lip abruptly reflexed and expanded, apex acute .. .. 6. *C. rotundifolia.*

Leaf $\frac{1}{2}$–2 in., petiolate, orbicular or reniform, 3-lobed at the tip. Upper sepal obtuse. Lip abruptly reflexed and expanded, apex rounded .. .. 7. *C. triloba.*

Large and stout, 2–8 in. high. Leaf on a petiole $\frac{1}{2}$–3 in. long; lamina $\frac{1}{2}$–3 in., broadly oblong or orbicular. Upper sepal acute. Lip large, abruptly reflexed and much expanded .. .. 8. *C. macrantha.*

1. **C. Cheesemanii** *Hook. f. ex T. Kirk in Trans. N.Z. Inst.* iii (1871) 180.—A very small species, $\frac{1}{2}$–1 in. high when in flower, rarely more. Leaf sessile, $\frac{1}{4}$–$\frac{1}{2}$ in. long, ovate-cordate or orbicular-cordate, apiculate, membranous, veins conspicuous when dry. Flower sessile or shortly peduncled, about $\frac{5}{8}$ in. long, dull-purple; bract short, sheathing. Upper sepal very large, helmet-shaped, curved over the lip, obtuse. Lateral sepals minute, subulate, erect, placed between the basal spurs of the lip. Petals frequently wanting, when present very minute, deflexed, placed under or behind the basal spurs of the lip. Lip very large, tubular, the margins involute and meeting behind the column and enclosing it, the base produced downwards on each side into a short conical spur; the mouth expanded and abruptly recurved; margins entire. Column short, stout, erect, with a large fleshy gland at the base. Anther terminal, very

large. Capsule $\frac{1}{3}$ in. long, linear-oblong, elevated on the greatly elongated peduncle, which is sometimes over 6 in. long.—*Hook. Ic. Plant.* (1872) t. 1120; *Cheesem. Man. N.Z. Fl.* (1906) 693.

North Island: Auckland—Kaitaia, *R. H. Matthews!* *H. Carse!* Helena Bay, *Mrs. E. Bradney!* vicinity of Auckland, *T. F. C.* South Island: Near Westport, *W. Townson!* June–July.

A very curious little plant, probably not uncommon, but easily overlooked, from its small size and early flowering-period. It is very closely allied to the Australian *C. bicalcarata*, and may prove identical with it.

Corybas Hatch 75:367.

2. **C. Carsei** (*Cheesem.*) *in Trans. N.Z. Inst.* xliv (1911) 162.—A small delicate species, $\frac{1}{2}$–$\frac{2}{3}$ in. high when in flower. Leaf sessile, $\frac{1}{4}$–$\frac{1}{2}$ in. long, ovate-cordate, acute, membranous. Flower sessile or very shortly pedunculate, about $\frac{1}{2}$ in. long, horizontal or deflexed, dull-purplish. Upper sepal very narrow at the base, then suddenly expanded, so that the upper two-thirds is broadly oblong and hood-shaped, extreme tip incurved and emarginate and slightly thickened and papillose. Lateral sepals placed under the lip, small, narrow-linear, 4–5 mm. long. Lateral petals still smaller, 3 mm. long. Lip large, tubular, the margins involute, meeting behind the column and enclosing it, orbicular or broader than long when spread out, extreme tip produced into a minute projecting lamina, between which and the overhanging emarginate tip of the upper sepal is the only entrance to the front of the flower. Immediately inside the entrance the surface of the lip is furnished with a broad patch of stiff papillae all pointing towards the interior of the flower, and which is continued as a narrow band down the median line of the lip. At the base of the lip the margins on each side are rolled up on themselves, thus forming two minute circular openings leading to the base of the flower. Column short, stout, curved. Capsule not seen.

North Island: Peaty swamps between Lake Tongonge and the coast, Mongonui County, *H. Carse* and *H. B. Matthews!*

A very curious little plant, closely allied to the Australian *C. unguiculata*. But, judging from Mr. Fitzgerald's beautiful drawing, that species has a much broader flower, the upper sepal is wider and not incurved or emarginate at the tip, the projecting lamina at the apex of the lip is much smaller, and the papillae within the lip are confined to the median line, whereas they also form a broad patch to the right and left of the median line in *C. Carsei*. There is also a relationship to *C. Matthewsii*; but, among other differences, that plant has a much narrower dorsal sepal, and the lip wants the projecting lamina of *C. Carsei*.

= Corybas unguiculatus (R. Br.) Reichb. f. Beitr. Syst. Pfl. 43

3. **C. Matthewsii** *Cheesem. in Trans. N.Z. Inst.* xxxi (1899) 351.—Small, delicate, $\frac{3}{4}$–$1\frac{1}{2}$ in. high. Leaf sessile, $\frac{1}{2}$–1 in. long, ovate-cordate or orbicular-cordate, acute or obtuse, membranous when dry, showing 1 or 2 circular veins on each side of the midrib connected by transverse veinlets. Flower shortly peduncled, about $\frac{1}{3}$ in. long, horizontal or drooping, purplish-green; bract small, erect. Upper sepal very narrow at the base, broadened above and hood-shaped, arched over the lip. Lateral sepals and petals small, linear-subulate, seldom more than $\frac{1}{2}$ as long as the lip. Lip large, involute, the margins meeting behind the column and enclosing it, orbicular-cordate when spread out; base with a rounded auricle on each side; apex truncate, entire or very slightly denticulate; disc with a thickened patch covered with deflexed hairs. Column short, stout, curved, swollen in front at the base.—*Cheesem. Man. N.Z. Fl.* (1906) 693; *Ill. N.Z. Fl.* ii (1914) t. 199A.

Corybas matthewsii (Cheeseman) Schltr. in Fedde Repert. 1923, 19:23.

NORTH ISLAND: Auckland—Kaitaia (Mongonui County), *R. H. Matthews! H. B. Matthews! H. Carse!* Aponga (Whangarei County), *A. Thompson!*

Clearly allied to *C. oblonga*, but the flower is larger, the lateral sepals and petals much reduced in size, the upper sepal narrower at the base and more hood-shaped at the top, and the margin of the lip is not coarsely fringed.

Corybas oblongus (Hook. f.) Reichb. f. Beitr. Syst. Pl. 67.

4. **C. oblonga** *Hook. f. Handb. N.Z. Fl.* (1864) 266.—Variable in size, ½–2 in. high. Leaf sessile, ¾–1½ in. long, ovate-oblong, apiculate, rounded or cordate at the base, thin and membranous, conspicuously veined when dry. Flowers small, shortly peduncled, solitary or very rarely two together, about ¼ in. long, reddish-purple; bract rather large, sometimes foliaceous, erect. Upper sepal narrow, concave, oblong when spread out, obtuse or apiculate, arched over the lip. Lateral sepals and petals filiform, ¼–¾ in. long. Lip involute, the margins meeting behind the column and enclosing it, broadly semicordate when spread out; base with a rounded auricle or orifice on each side; apex truncate, coarsely toothed or fimbriate, centre of disc with minute dentiform papillae. Column short, stout, curved to the front, with a swelling at the base.—*Cheesem. Man. N.Z. Fl.* (1906) 694; *Ill. N.Z. Fl.* ii (1914) t. 199B. Nematoceras oblonga *Hook. f. Fl. Nov. Zel.* i (1853) 250, t. 57B.

NORTH AND SOUTH ISLANDS, STEWART ISLAND: Not uncommon on moist shaded banks from the North Cape southwards. AUCKLAND ISLANDS: North arm of Carnley Harbour, *B. C. Aston!* Sea-level to 2000 ft. September–November.

Corybas rivularis (Hook. f.) Reichb. f. Beitr. Syst. Pl. 67

5. **C. rivularis** *Hook. f. Handb. N.Z. Fl.* (1864) 266.—Very delicate and membranous, 1–2½ in. high. Leaf sessile, ½–2 in. long, ovate or oblong-ovate, acuminate, deeply cordate or almost 2-lobed at the base, very thin and membranous, veins conspicuous, reticulated. Flower shortly pedunculate or sessile between the lobes of the leaf, ⅓–½ in. long; bract narrow, acuminate. Upper sepal narrow, concave, arched over the lip, gradually tapering into a long filiform point. Lateral sepals and petals filiform, 1–2 in. long, the petals usually exceeding the sepals. Lip involute, the margins meeting behind the column and enclosing it, broadly ovate-cordate when spread out; base with a rounded auricle or orifice on each side; upper portion curved forwards and downwards, acuminate or apiculate, margins undulate, entire. Column very short, stout, erect.—*Cheesem. Man. N.Z. Fl.* (1906) 694. Nematoceras rivularis *Hook. f. Fl. Nov. Zel.* i (1853) 251. Acianthus rivularis *A. Cunn. Precur.* (1836) n. 312; *Hook. f. Fl. Antarct.* i (1844) 71.

NORTH AND SOUTH ISLANDS, STEWART ISLAND, AUCKLAND ISLANDS: In damp wooded ravines from the North Cape southwards, but often local. Sea-level to 2000 ft. September–November.

A very remarkable and distinct species, easily recognized by the thin acuminate leaf, very long filiform petals and lateral sepals, by the filiform point to the upper sepal, and acuminate lip.

Rea Hatch 75: 367

6. **C. rotundifolia** *Hook. f. Handb. N.Z. Fl.* (1864) 266.—Variable in size, ½–2 in. high. Leaf sessile or shortly petiolate, ½–1¼ in. long, broadly oblong or orbicular, tip rounded and apiculate, deeply cordate or 2-lobed at the base, rather fleshy, membranous when dry, veins reticulated. Peduncle at first very short, but elongating as the flower withers. Flower ½ in. long, dull-purple or purplish-green; bract short. Upper sepal narrow, concave, arched over the lip, acuminate. Lateral sepals and petals filiform, 1–1½ in. long. Lip tubular below, the margins meeting behind the column

and enclosing it, base with a rounded auricle on each side; upper part abruptly recurved and expanded, tip acute, margins very minutely denticulate. Column short, stout, bent backwards.—*Cheesem. Man. N.Z. Fl.* (1906) 695. C. orbiculata *Col. in Trans. N.Z. Inst.* xxiii (1891) 389. Nematoceras rotundifolia *Hook. f. Fl. Nov. Zel.* i (1853) 251.

Var. **pandurata** *Cheesem.*—Leaves deeply lobed on each side, so as to be almost panduriform. Other characters precisely as in the type.

North and South Islands, Stewart Island, Auckland and Campbell Islands: Moist wooded ravines throughout, but often local. Sea-level to 2500 ft. September–December. Var. *pandurata:* Kaitaia (Mongonui County), *R. H. Matthews!*

This may not be the *C. rotundifolia* of the Handbook, which is described as having a truncate lip. It differs from *C. rivularis* in the more coriaceous leaf, with a rounded tip, in the upper sepal not being produced into a filiform point, and in the broader reflexed portion of the lip. From small forms of *C. macrantha* it is best distinguished by the almost sessile leaf and much smaller lip with an acute or acuminate tip.

Corybas trilobatus (Hook.f.) Reichb.f. Beitr. Syst. Fl. 67

7. **C. triloba** *Hook. f. Handb. N.Z. Fl.* (1864) 265.—Rather stout, variable in size. Leaf on a petiole ½–2 in. long; blade ½–1½ in. diam., reniform or orbicular, more or less distinctly 3-lobed at the tip, middle lobe acute, cordate at the base, fleshy when fresh, membranous when dry. Peduncle at first short, but elongating as the flower withers, and in fruit often 4–8 in. long. Flower ⅓–½ in. long, dull-purple; bract rather small. Upper sepal narrow at the base, dilated above, obovate-spathulate when spread out, arched over the lip, concave, obtuse at the tip. Lateral sepals and petals filiform, erect, ¾–2 in. long. Lip involute, tubular below, the margins meeting behind the column and enclosing it, and with a rounded auricle or orifice at the base on each side; upper part abruptly reflexed and much expanded laterally and downwards, forming a broad saucer-like entrance to the flower; margins erose or nearly entire. Column short, stout, bent backwards.—*Cheesem. Man. N.Z. Fl.* (1906) 695. C. hypogea *Col. in Trans. N.Z. Inst.* xvi (1884) 336. Nematoceras triloba *Hook. f. Fl. Nov. Zel.* i (1853) 250.

North and South Islands, Stewart Island: Shaded places from the North Cape southwards, but often local. Sea-level to 4000 ft. July–September. June 4.B.

Corybas macranthus (Hook.f.) Reichb.f.

8. **C. macrantha** *Hook. f. Handb. N.Z. Fl.* (1864) 266.—Much larger than the other species, 2–8 in. high or more. Leaf on a petiole ½–3 in. long; lamina ¾–2 in. diam., broadly oblong or orbicular, obtuse or apiculate or rarely 3-lobed at the tip, cordate or 2-lobed at the base, thick and fleshy when fresh, thin and membranous when dry, veins finely reticulate. Peduncle from the base of the petiole, at first short, but elongating as the flower withers, often 4–10 in. long in fruit. Flower large, ½–1 in. long, dark-purple; bract small. Upper sepal narrow, concave, arched over the lip, somewhat expanded above, acute or acuminate. Lateral sepals and petals filiform, 1–2 in. long. Lip large, tubular below, the margins meeting behind the column and enclosing it, base with a rounded auricle on each side, upper part abruptly recurved and much expanded all round, margins undulate, minutely erose or denticulate. Column short, stout, bent backwards.—*Cheesem. Man. N.Z. Fl.* (1906) 696. C. papillosa *Col. in Trans. N.Z. Inst.* xvi (1884) 337. Nematoceras macrantha *Hook. f. Fl. Nov. Zel.* i (1853) 229, t. 57A.

See also Hatch 76:519 & 580.

North and South Islands, Stewart Island, Chatham Islands, Auckland and Campbell Islands: Not uncommon in damp shaded places throughout. Sea-level to 4000 ft. October–December.

Closely allied to *C. triloba*, but much larger, the leaves rarely 3-lobed at the tip, the upper sepal acute or acuminate, and the lip larger. Both it and *C. triloba* frequently have the peduncle bent backwards, so that the flower lies with the upper sepal uppermost and the lip above.

1870 : 330.

21. GASTRODIA R. Br. See Hook. 77 : 232.

Leafless terrestrial brownish herbs. Root long, tuberous, usually parasitic on the roots of other plants. Stem simple, erect, furnished with lax sheathing scales. Flowers in a terminal raceme. Sepals and petals connate into a ventricose 5-lobed tube more or less slit on the anterior side. Lip shorter than the perianth, attached at the base to the foot of the column, and adnate at the back to the perianth-tube; lamina erect, furnished with longitudinal raised lines or naked, margins undulate. Column long or short, narrowly 2-winged; rostellum small; stigma near the base of the column, prominent. Anther lid-like, incumbent; pollinia free, granular.

A small genus of 10 or 12 species, ranging from New Zealand and Australia northwards to Malaya, the Himalayas, China, and Japan.

Raceme 2–8 in., many-flowered. Perianth $\frac{3}{4}$ in. Column elongated, $\frac{2}{3}$ the length of the lip	1. *G. sesamoides.*
Raceme 6–12 in., very many flowered. Perianth $\frac{1}{2}$ in. Column very short, barely $\frac{1}{4}$ the length of the lip	2. *G. Cunninghamii.*
Stem slender, almost filiform. Raceme 1–3 in., 3–5-flowered. Perianth $\frac{1}{2}$ in. Column very short, barely $\frac{1}{4}$ the length of the lip	3. *G. minor.*

G. Hectori Buch. in Trans. N.Z. Inst. xix (1887) 214 is shown by the specimens in Mr. Buchanan's herbarium to be a *Prasophyllum*, probably *P. patens* R. Br.

1. **G. sesamoides** *R. Br. Prodr.* (1810) 330.—Root very long and tuberous. Stem stout or slender, 1–2½ ft. high, mottled grey; sheathing scales loose, truncate or with an obtuse point. Raceme 2–8 in. long, many-flowered; bracts scarious, broadly ovate, shorter than the pedicels. Flowers brownish-white, about $\frac{2}{3}$ in. long without the ovary, drooping. Perianth ventricose, gibbous at the base, shortly 5-lobed; lobes short and broad, ovate, constricted at the base. Lip slightly shorter than the perianth; lamina oblong, with 2 thick ridges up the median line, which coalesce into one near the tip, margins much crisped and undulate. Column elongate, almost as long as the lip, angular, narrowly winged above; stigma a large protuberance at the very base.—*Hook. f. Fl. Tasm.* ii (1860) 31, t. 126; *Benth. Fl. Austral.* vi (1873) 309; *Fitzgerald Austral. Orch.* ii (1891) pt. 5; *Cheesem. Man. N.Z. Fl.* (1906) 697.

North Island: Auckland—Kaitaia, *R. H. Matthews! H. B. Matthews!* Northern Wairoa, *T. F. C.;* Opepe, Taupo, *T. F. C.;* East Cape district, *Adams* and *Petrie!* South Island: Westland, Kelly's Creek, *Petrie!* Sea-level to 1500 ft. December–January.

The long slender column at once separates this from the following species, which it otherwise much resembles. In Australia it ranges from Queensland to Tasmania.

2. **G. Cunninghamii** *Hook. f. Fl. Nov. Zel.* i (1853) 251.—Habit and appearance of *G. sesamoides* but usually smaller and more slender, 1–3 ft. high or even more. Stem brownish, often striped and spotted with purple or fawn colour. Raceme 6–10 in. long, very many flowered, pedicels slender, $\frac{1}{5}$–$\frac{1}{3}$ in.; bracts ovate, acute, scarious. Flowers brownish-white, $\frac{1}{2}$ in. long

without the ovary, drooping. Perianth tubular, much swollen at the base, split half-way down on the anterior face, shortly 5-lobed; lobes broad, ovate-deltoid, acute. Lip rather shorter than the perianth; lamina narrow trowel-shaped with 2 papillose ridges running up the middle and uniting near the tip; margins involute, membranous, much crisped and undulate. Column very short, barely $\frac{1}{4}$ the length of the lip.—*Handb. N.Z. Fl.* (1864) 263; *Petrie in Trans. N.Z. Inst.* xxv (1893) t. 20, f. 1–4; *Cheesem. Man. N.Z. Fl.* (1906) 697. G. leucopetala *Col. in Trans. N.Z. Inst.* xviii (1886) 268.

North and South Islands, Stewart Island, Chatham Islands: Not uncommon in dark shaded places, but easily overlooked. Sea-level to 2000 ft. *Perei; Makaika.* November–January.

The starchy thick and tuberous root was formerly collected by the Maoris and eaten, especially in the Urewera district.

3. **G. minor** *Petrie in Trans. N.Z. Inst.* xxv (1893) 273, t. 20, f. 5–7.—Stem umber-brown, not spotted, very slender, 8–15 in. high, $\frac{1}{12}$ in. diam. at the base; sheathing scales few, oblique. Raceme 1–3 in. long, 3–5-flowered; pedicels slender, $\frac{1}{5}$ in. long; bracts short, broad, scarious. Flowers brownish tipped with dirty-white, $\frac{1}{2}$ in. long without the ovary, drooping. Perianth ventricose, gibbous at the base, split about half-way down on the anterior side, shortly 5-lobed; lobes rounded-ovate, undulate. Lip hardly shorter than the perianth; lamina linear-oblong, obtuse, with 2 thick median ridges; margins incurved, thickened, slightly crumpled. Column very short, barely $\frac{1}{4}$ the length of the lip.—*Cheesem. Man. N.Z. Fl.* (1906) 697.

South Island: Otago—Opihi Creek, near Dunedin, *Petrie!* January.

Dried specimens differ very little in appearance from slender forms of *G. Cunninghamii;* but according to Mr. Petrie there are important differences in the lip and column.

Family XXIV. **PIPERACEAE.**

Herbs or shrubs, often aromatic and stimulating. Leaves alternate or opposite or whorled, simple, entire; stipules wanting, or 2 connate, or adnate to the petiole. Flowers minute, hermaphrodite or unisexual, crowded on axillary or terminal catkin-like spikes, each subtended by a sessile or stipitate bract. Perianth wanting. Stamens 2 or more, hypogynous; filaments very short; anthers often jointed on the filaments, cells 2 or confluent. Ovary (except in the tribe *Saurureae*, which does not occur in New Zealand) 1-celled, with a single orthotropous ovule; style wanting or very short; stigmas 1–6, various in shape. Fruit a small indehiscent berry. Seed solitary, globose or ovoid or oblong; albumen copious, farinaceous; embryo very minute, enclosed in a sac at the apex of the seed.

A large family, with some trifling exceptions confined to tropical and subtropical regions, and far more abundant in tropical America than anywhere else. Genera 8; species given at 1,000, but probably overestimated. Aromatic and stimulating properties prevail through the greater part of the family. The common pepper has been used as a spice since the times of Alexander, and other species of *Piper* can be similarly employed. The use of the betel (*Piper betel*) as a masticatory is well known, also that of the kava (*Macropiper methysticum*) to prepare an intoxicating drink.

Usually shrubby. Anther-cells 2, distinct. Stigmas 2–4 .. 1. Macropiper.
Small fleshy herbs. Anther-cells confluent. Stigmas usually penicillate. Fruit very small .. .. 2. Peperomia.

1. **MACROPIPER** Miq.

Shrubs or small trees ; branches often jointed and swollen at the nodes. Leaves alternate, entire, equal or unequal at the base ; stipules often adnate to the petiole. Spikes unisexual, dense, axillary, solitary or 2–3 together in the upper axils. Flowers very small and numerous, densely packed. Stamens 2–3 ; cells of the anthers distinct, parallel or divergent. Berries numerous in the spike, often connate with the bracts and rhachis into a subsucculent or fleshy fruit.

A small genus of some 5 or 6 species, found in New Zealand, Norfolk Island, Lord Howe Island, and thence eastwards to Tahiti and northwards to New Guinea.

1. **M. excelsum** (*Miq. Syst. Pip.* (1843) 221.—An aromatic prefectly glabrous densely branched shrub or small tree 8–20 ft. high ; branches smooth, flexuose, jointed and swollen at the nodes. Leaves petiolate, 2–5 in. long including the petiole, orbicular-cordate or broadly ovate, shortly acuminate, cordate at the base or sometimes truncate or rounded,

228 ; *Handb. N.Z. Fl.* (1864) 254 ; *Cheesem. Man. N.Z.* Fl. (1906) 596.

Var. **psittacorum** *R. M. Laing in Trans. N.Z. Inst.* xlvii (1915) 22.—Leaves larger, 4–8 in. long, usually 9-nerved. Spikes longer, often over 6 in. long.—*W. R. B. Oliver in Trans. N.Z. Inst.* xlix (1917) 132. Piper psittacorum *Endl. Prodr. Norflk.* (1833) 37.

KERMADEC ISLANDS : Var. *psittacorum* abundant, *McGillivray, T. F. C., W. R. B. Oliver!* NORTH ISLAND : Var. *psittacorum* common on the Three Kings Islands, also on the Poor Knights, the Little Barrier, and Tiritiri Islands ; the ordinary form abundant in lowland districts. SOUTH ISLAND : Near the coast-line from Nelson and Marlborough southwards to Banks Peninsula and Okarito. CHATHAM ISLANDS : Not uncommon, *H. H. Travers! F. A. D. Cox!* *Kawakawa ; Pepper-tree.* Flowers most of the year.

The variety plentiful in Norfolk Island and Lord Howe Island, also recorded from Tahiti and others of the Pacific islands. The fruit and leaves of the ordinary form are aromatic and stimulating, and a decoction of the latter has been used for toothache.

2. **PEPEROMIA** Ruiz and Pavon.

Annual or perennial herbs, usually succulent. Leaves alternate or opposite or whorled, fleshy or more rarely membranous, often pellucid-dotted ; stipules wanting. Spikes slender, terminal or axillary or leaf-opposed, solitary or fascicled. Flowers hermaphrodite, minute, sessile or sunk in the rhachis of the spike, bracteate ; the bract frequently peltate. Perianth wanting. Stamens 2 ; filaments very short ; anther-cells confluent. Ovary sessile, obtuse or acute, 1-celled ; stigma usually penicillate ; ovule solitary, erect. Fruit minute, indehiscent ; seed with a membranous testa.

without the ovary, drooping. Perianth tubular, much swollen at the base, split half-way down on the anterior face, shortly 5-lobed; lobes broad, ovate-deltoid, acute. Lip rather shorter than the perianth; lamina narrow trowel-shaped with 2 papillose ridges running up the middle and uniting near the tip; margins involute, membranous, much crisped and undulate. Column very short, barely $\frac{1}{4}$ the length of the lip.—*Handb. N.Z. Fl.* (1864) 263; *Petrie in Trans. N.Z. Inst.* xxv (1893) t. 20, f. 1–4; *Cheesem. Man. N.Z. Fl.* (1906) 697. G. leucopetala *Col. in Trans. N.Z. Inst.* xviii (1886) 268.

North and South Islands, Stewart Island, Chatham Islands: Not uncommon in dark shaded places, but easily overlooked. Sea-level to 2000 ft. *Perei; Makaika.* November–January.

The starchy thick and tuberous root was formerly collected by the Maoris and eaten, especially in the Urewera district.

3. **G. minor** *Petrie in Trans. N.Z. Inst.* xxv (1893) 273, t. 20, f. 5–7.—[illegible] not spotted, very slender, 8–15 in. high, $\frac{1}{12}$ in. diam. at [illegible]

South Island: Otago [illegible]

Dried specimens differ very little in appearance from slender forms of *G. Cunninghamii*; but according to Mr. Petrie there are important differences in the lip and column.

Family XXIV. **PIPERACEAE.**

Herbs or shrubs, often aromatic and stimulating. Leaves alternate or opposite or whorled, simple, entire; stipules wanting, or 2 connate, or adnate to the petiole. Flowers minute, hermaphrodite or unisexual, crowded on axillary or terminal catkin-like spikes, each subtended by a sessile or stipitate bract. Perianth wanting. Stamens 2 or more, hypogynous; filaments very short; anthers often jointed on the filaments, cells 2 or confluent. Ovary (except in the tribe *Saurureae*, which does not occur in New Zealand) 1-celled, with a single orthotropous ovule; style wanting or very short; stigmas 1–6, various in shape. Fruit a small indehiscent berry. Seed solitary, globose or ovoid or oblong; albumen copious, farinaceous; embryo very minute, enclosed in a sac at the apex of the seed.

A large family, with some trifling exceptions confined to tropical and subtropical regions, and far more abundant in tropical America than anywhere else. Genera 8; species given at 1,000, but probably overestimated. Aromatic and stimulating properties prevail through the greater part of the family. The common pepper has been used as a spice since the times of Alexander, and other species of *Piper* can be similarly employed. The use of the betel (*Piper betel*) as a masticatory is well known, also that of the kava (*Macropiper methysticum*) to prepare an intoxicating drink.

Usually shrubby. Anther-cells 2, distinct. Stigmas 2–4 .. 1. Macropiper.
Small fleshy herbs. Anther-cells confluent. Stigmas usually penicillate. Fruit very small .. .. 2. Peperomia.

1. **MACROPIPER** Miq.

Shrubs or small trees ; branches often jointed and swollen at the nodes. Leaves alternate, entire, equal or unequal at the base ; stipules often adnate to the petiole. Spikes unisexual, dense, axillary, solitary or 2–3 together in the upper axils. Flowers very small and numerous, densely packed. Stamens 2–3 ; cells of the anthers distinct, parallel or divergent. Berries numerous in the spike, often connate with the bracts and rhachis into a subsucculent or fleshy fruit.

A small genus of some 5 or 6 species, found in New Zealand, Norfolk Island, Lord Howe Island, and thence eastwards to Tahiti and northwards to New Guinea.

1. **M. excelsum** (*Miq. Syst. Pip.* (1843) 221.—An aromatic prefectly glabrous densely branched shrub or small tree 8–20 ft. high ; branches smooth, flexuose, jointed and swollen at the nodes. Leaves petiolate, 2–5 in. long including the petiole, orbicular-cordate or broadly ovate, shortly acuminate, cordate at the base or sometimes truncate or rounded, 7-nerved from the base, smooth and glabrous on both surfaces, yellowish-green ; petioles ½–1½ in. long, lower portion broadly winged on each side by the adnate stipules. Spikes unisexual, solitary or binate, terminating short peduncles or branchlets springing from the axils of the leaves, slender, strict, erect, 1–3 in. long. Flowers minute, very densely packed, the bract orbicular-peltate, sessile. Stamens 2 or rarely 3. Stigmas 3 or rarely 4. Berries densely compacted, small, yellow, broadly obovoid, angled, succulent.—*F. Muell. Veg. Chath. Is.* (1864) 48. Piper excelsum *Forst. f. Prodr.* (1786) n. 20 ; *A. Rich. Fl. Nouv. Zel.* (1832) 356 ; *A. Cunn. Precur.* (1836) n. 323 ; *Raoul Choix* (1846) 42 ; *Hook. f. Fl. Nov. Zel.* i (1853) 228 ; *Handb. N.Z. Fl.* (1864) 254 ; *Cheesem. Man. N.Z.* Fl. (1906) 596.

Var. **psittacorum** *R. M. Laing in Trans. N.Z. Inst.* xlvii (1915) 22.—Leaves larger, 4–8 in. long, usually 9-nerved. Spikes longer, often over 6 in. long.—*W. R. B. Oliver in Trans. N.Z. Inst.* xlix (1917) 132. Piper psittacorum *Endl. Prodr. Norflk.* (1833) 37.

Kermadec Islands : Var. *psittacorum* abundant, *McGillivray, T. F. C., W. R. B. Oliver !* North Island : Var. *psittacorum* common on the Three Kings Islands, also on the Poor Knights, the Little Barrier, and Tiritiri Islands ; the ordinary form abundant in lowland districts. South Island : Near the coast-line from Nelson and Marlborough southwards to Banks Peninsula and Okarito. Chatham Islands : Not uncommon, *H. H. Travers ! F. A. D. Cox !* *Kawakawa ; Pepper-tree.* Flowers most of the year.

The variety plentiful in Norfolk Island and Lord Howe Island, also recorded from Tahiti and others of the Pacific islands. The fruit and leaves of the ordinary form are aromatic and stimulating, and a decoction of the latter has been used for toothache.

2. **PEPEROMIA** Ruiz and Pavon.

Annual or perennial herbs, usually succulent. Leaves alternate or opposite or whorled, fleshy or more rarely membranous, often pellucid-dotted ; stipules wanting. Spikes slender, terminal or axillary or leaf-opposed, solitary or fascicled. Flowers hermaphrodite, minute, sessile or sunk in the rhachis of the spike, bracteate ; the bract frequently peltate. Perianth wanting. Stamens 2 ; filaments very short ; anther-cells confluent. Ovary sessile, obtuse or acute, 1-celled ; stigma usually penicillate ; ovule solitary, erect. Fruit minute, indehiscent ; seed with a membranous testa.

A large genus of about 500 species, widely spread in almost all tropical regions, but most plentiful in South America.

Leaves in whorls of 4, coriaceous when dry. Spikes terminal.. 1. *P. tetraphylla.*
Leaves alternate, thin and membranous when dry. Spikes terminal and axillary .. .. 2. *P. Urvilliana.*

(Forst. f.)

1. **P. tetraphylla** *Hook. and Arn. Bot. Beech. Voy.* (1830–41) 96.—Small, succulent, erect or spreading, much branched from the base, 4–9 in. high; branches deeply grooved when dry, pubescent at the nodes. Leaves in whorls of 3 or 4, rarely opposite, shortly petiolate or almost sessile, ¼–½ in. long, elliptic-rhomboidal or almost orbicular, obtuse, fleshy when fresh, coriaceous when dry, dark-green above, paler beneath, minutely punctate; young leaves beneath and petioles finely pubescent; veins obscure. Spikes slender, terminal, pedunculate, ¾–1½ in. long, dense-flowered; peduncle and rhachis pubescent. Bract orbicular-peltate, almost sessile. Ovary partly immersed in the rhachis, ovate, acute; stigma capitellate. Berry exserted, ovoid, reddish, $\frac{1}{20}$ in. long.—*W. R. B. Oliver in Trans. N.Z. Inst.* xlix (1917) 133. P. reflexa *A. Dietr. Sp. Plant.* i (1831) 180; *Benth. Fl. Austral.* vi (1873) 206; *Cheesem. Man. N.Z. Fl.* (1906) 596. P. novae-zealandiae *Col. in Trans. N.Z. Inst.* xxvii (1895) 394. Piper tetraphyllum *Forst. f. Prodr.* (1786) n. 25. P. aemulum *Endl. Prodr. Fl. Norfl.* (1833) 36.

North Island: Woods near the East Cape, on prostrate logs or trunks of living trees, specially abundant in the valley of the Tuparoa River, and extending within 4 or 5 miles of the base of Mount Hikurangi, *G. T. Williams! H. Hill!*

A common plant in most tropical countries. It is found in several parts of Australia and Polynesia, advancing as near to New Zealand as Lord Howe Island and Norfolk Island.

e.?

2. **P. Urvilliana** *A. Rich. Fl. Nouv. Zel.* (1832) 356.—A small glabrous succulent herb 6–12 in. high; stems sparingly branched, prostrate and rooting at the base, ascending or erect above. Leaves alternate, shortly petiolate, ½–1¼ in. long, broadly obovate or elliptic-oblong, sometimes almost orbicular, rounded at the tip or rarely subacute, 3-nerved at the base, glabrous, very thick and fleshy when fresh, thin and often almost pellucid when dry. Spikes terminal and axillary, solitary, peduncled, 1–2 in. long. Bract orbicular-peltate. Ovary partly immersed; stigma discoid. Berry exserted or immersed at the base.—*A. Cunn. Precur.* (1836) n. 324; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 228; *Handb. N.Z. Fl.* (1864) 254. P. Endlicheri *Miq. Syst. Pip.* (1843) 102; *Cheesem. Man. N.Z. Fl.* (1906) 596. Piper simplex *Endl. Prodr. Fl. Norfl.* (1833) 37.

Kermadec Islands, North Island: In lowland stations on rocks and trees in damp shady places as far south as Taranaki and Hawke's Bay, from thence less common to Cook Strait. South Island: Limestone rocks in Golden Bay, Nelson, *B. C. Aston.* Flowers most of the year.

Also found in Norfolk Island and Lord Howe Island. I suspect that Colenso's *P. muricatulata* (Trans. N.Z. Inst. xxvii (1895) 393) is a large-leaved state, but there are no specimens in his herbarium, and it is impossible to be sure from the description alone.

Family XXV. **CHLORANTHACEAE.**

Shrubs or trees, rarely herbs, generally aromatic. Leaves opposite, usually toothed, petioles often connate at the base; stipules small, subulate. Flowers small, unisexual, in terminal or axillary spikes or panicles. Perianth wanting (rarely present in the female flowers). Stamens either 1 or 3 connate; filaments short and thick; anthers 2-celled, or when there are 3 the lateral 1-celled. Ovary 1-celled; stigma either sessile or style very short; ovule solitary, orthotropous, pendulous from the top of the cell. Fruit a small globose or ovoid drupe. Seed pendulous; testa membranous; albumen copious, fleshy; embryo minute, remote from the hilum, radicle inferior.

A small and unimportant family, comprising 3 genera and 35 species, mostly tropical or subtropical.

1. **ASCARINA** Forst. 1776. p. 117. t. 59.

Aromatic shrubs or small trees; branchlets jointed at the nodes. Leaves opposite, serrate, penniveined; petioles connate at the base into a short sheath; stipules small, subulate. Flowers minute, dioecious or monoecious, arranged in simple or branched spikes. Perianth wanting in both sexes. Male flowers: Stamen solitary; anther sessile, linear-oblong, cylindric, 2-celled; cells parallel, dehiscing longitudinally. Female flowers: Ovary naked, ovoid or subglobose; stigma sessile, truncate. Drupe small, putamen fragile.

A small genus of six species, all very closely allied, found in New Zealand and the Pacific islands from New Caledonia eastwards to Tahiti.

Leaves 2–4 in., ovate- or oblong-lanceolate, acuminate. Anthers $\frac{1}{8}$ in. long .. .. 1. *A. lanceolata.*
Leaves 1–2 in., elliptic-oblong or obovate-oblong, obtuse or acute. Anthers $\frac{1}{10}$ in. long .. .. 2. *A. lucida.*

1. **A. lanceolata** *Hook. f. in Journ. Linn. Soc.* (1856) 127.—A perfectly glabrous bushy shrub or small tree 6–15 ft. high, rarely more; branches dark purplish-red, striate when dry. Leaves 2–4 in. long including the petiole, ovate-lanceolate or oblong-lanceolate, acuminate, narrowed into the petiole, dark-green and glossy above, paler beneath; margins coarsely serrate, the teeth often curved and acute; petioles $\frac{1}{2}$–$\frac{3}{4}$ in. long. Spikes closely branched in a racemiform manner, 1–2 in. long; branches opposite, springing from the axils of a pair of connate bracts. Male flowers alone seen, rather closely placed, each one in the axil of a broadly ovate acute bract, and with a smaller bracteole on each side. Anther sessile, $\frac{1}{8}$ in. long, linear-oblong, cylindric; connective thick, produced at the tip into a minute usually recurved apiculus.—*Solms in DC. Prodr.* xvi, 1 (1869) 478; *Cheesem. Man. N.Z. Fl.* (1906) 597.

Kermadec Islands: Not uncommon in forest on Sunday Island, *McGillivray, T. F. C., W. R. B. Oliver!* June–September.

This was reduced to *A. lucida* in the Handbook, but appears to be sufficiently distinct in the larger and narrower more acuminate leaves, and larger anthers. The same species, or a very close ally, is found in Fiji, Samoa, and Rarotonga.

2. **A. lucida** *Hook. f. Fl. Nov. Zel.* i (1853) 228.—A perfectly glabrous closely branched shrub or small tree 10–25 ft. high, with a trunk 6–12 in. diam.; branches slender, terete, striate when dry, dark purplish-red.

Leaves 1–2 in. long including the petiole, obovate-oblong to elliptic-oblong or linear-oblong, obtuse or acute, cuneate at the base, dark-green and glossy above, often glaucous beneath, margins coarsely and often obtusely serrate ; petioles $\frac{1}{3}$ in. long. Spikes laxly branched in a racemiform manner, the females more slender and more sparingly divided than the males ; branches opposite, pendulous. Flowers minute, alternate, each one in the axil of a broadly ovate acute bract with a smaller bracteole on each side. Anther sessile, oblong, $\frac{1}{10}$ in. long. Female flowers sometimes 2 or 3 together. Ovary broadly ovoid ; stigma very broad, truncate. Ripe fruit not seen. — *Handb. N.Z. Fl.* (1864) 253 ; *T. Kirk Forest Fl.* (1889) t. 129 ; *Cheesem. Man. N.Z. Fl.* (1906) 598 ; *Ill. N.Z. Fl.* ii (1914) t. 166. A. rubricaulis *Solms in DC. Prodr.* xvi, 1 (1869) 478 (*in part*).

North Island : Auckland—Hokianga, *Buchanan ;* Bay of Islands, *T. Kirk ;* Whangarei, *H. Carse, T. F. C. ;* Little Barrier Island, *T. F. C. ;* Coromandel, *Petrie !* Waitakarei Ranges, *T. F. C. ;* near Waihi, *Petrie !* Taranaki — Mount Egmont, *Buchanan.* Wellington—Wairarapa Valley, *Colenso !* South Island : Marlborough—Queen Charlotte Sound, *Banks* and *Solander ;* Kenepuru, *J. Rutland !* Nelson—Cape Foulwind, *W. Townson !* Westland—Abundant along the whole length of the district, *Helms, Cockayne,* and others. Otago—Plentiful in the sounds of the south-west coast, *Hector, Buchanan, T. Kirk !* Stewart Island : *C. Trail* (*fide T. Kirk*). Sea-level to 2500 ft. September–November.

Although this extends along almost the whole length of the Dominion, it is only on the west coast of the South Island, from Westport to Preservation Inlet, that it is at all plentiful. Elsewhere it is extremely local.

Family XXVI. **FAGACEAE.**

Trees or shrubs. Leaves alternate, simple, penninerved, stipulate. Flowers monoecious. Male flowers in erect or pendulous spikes, or collected into globular or capitate clusters. Perianth simple, 4–6-lobed. Stamens 5–20, inserted at the base of the perianth ; filaments slender ; anthers 2-celled. Female flowers less numerous than the males, solitary or few together, often surrounded by scales or bracts which are frequently united into an entire or lobed involucre. Perianth adnate to the ovary or wanting ; limb minute. Ovary 3-celled, rarely 2–6-celled ; styles as many as the cells ; ovules geminate in each cell. Fruit a nut, enclosed or seated within the persistent and hardened involucre. Seed rarely more than one in each nut ; embryo with large and fleshy cotyledons ; radicle superior.

An important family, including 5 genera and about 375 species, for the most part confined to the Northern Hemisphere, and most abundant in the Temperate Zone, extending southwards to the mountains of the Malay Archipelago and Central America and Colombia, a very few species of one genus alone found in the South Temperate Zone. The order includes the oak, chestnut, and beech, and produces some of the most durable and valuable woods known. The single New Zealand genus is confined to the temperate portion of the Southern Hemisphere.

See Cockayne Monogr. Beech Fav. Arb. Dendrologica 1916 : 8 : 4 : 43 !

NOTHOFAGUS Blume.

Trees or rarely shrubs. Leaves evergreen in all the New Zealand species ; stipules caducous. Flowers monoecious. Males : 1 to 3 or 4 towards the top of a short erect or curved peduncle ; bracts numerous, caducous. Perianth campanulate, 4–6-lobed ; lobes imbricate. Stamens

8–16 or more; filaments filiform, exserted; anthers obling. Females: Minute, 1–3, sessile within a lobed involucre composed of several scales grown together at the base. Perianth-tube adnate to the ovary; limb 3–5-lobed. Ovary inferior, 3-celled; styles short, linear, stigmatose within; ovules 2 in each cell, pendulous from the top of the cell. Fruiting-involucres small, hard, lobed, armed with transverse scales or lamellae at the base; lobes ultimately splitting to the base. Nuts enclosed within the involucre, 3-celled. Seed pendulous; cotyledons plaited.

A genus composed of 13 or 14 species; 6 of which are endemic in New Zealand; 3 in Australia or Tasmania; and 4 or 5 from temperate South America. It is the southern representative of the beeches (*Fagus*) of the Northern Hemisphere, from which it only differs in the small evergreen leaves, few-flowered male heads, and in the small fruiting-involucres.

A. Fruiting-involucres clothed with recurved linear processes.

Leaves $\frac{1}{3}$–$\frac{1}{2}$ in., ovate-rhomboid, coriaceous, doubly crenate .. 1. *N. Menziesii.*

B. Fruiting-involucres with flat transverse lamellae.

Leaves $\frac{3}{4}$–1$\frac{1}{2}$ in., broadly ovate, obtuse, thin, veined, pubescent, deeply serrate .. .. 2. *N. fusca.*

Leaves $\frac{3}{4}$–1 in., oblong, apiculate, entire or obscurely toothed towards the tip .. .. 3. *N. apiculata.*

Leaves $\frac{2}{3}$–$\frac{3}{4}$ in., ovate, acute, entire, glabrous above, fulvous beneath. Involucre 4-valved .. .. 4. *N. Blairii.*

Leaves $\frac{1}{4}$–$\frac{3}{4}$ in., oblong, obtuse, entire, glabrous above, white beneath. Involucre 3-valved .. .. 5. *N. Solandri.*

Leaves $\frac{1}{6}$–$\frac{2}{3}$ in., ovate, acute, rounded or cordate at the base, glabrous above, white beneath. Involucre 3-valved .. .. 6. *N. cliffortioides.*

The six species of *Nothofagus* enumerated above constitute a large proportion of the forests of the South Island, and even in the central and southern portions of the North Island the area now or recently covered by several species of the genus is by no means small. The economic value of these forests is much larger than is usually supposed, and under the pressure of the world-wide scarcity of timber may be expected to become much greater. Under such circumstances, considerable interest attaches to the discovery by Dr. Cockayne of the remarkable fact that hybridism on an enormous scale is constantly taking place between several of the species of *Nothofagus*, and that the resulting hybrids intercross. Dr. Cockayne's conclusions cannot fail to affect our present ideas on the classification of the species. His work is still in progress; but I am happy to publish in this place a short memorandum furnished by him at my request, giving an abstract of the chief results of his work.

"Hybridism in *Nothofagus*: After a personal examination of the *Nothofagus* forests in many localities in Wellington, Nelson, Marlborough, Canterbury, Westland, Otago, and Southland, together with a critical examination of many hundreds of specimens (seedling to adult) collected in all parts of the *Nothofagus* area of distribution, I have, unhesitatingly, come to the following conclusions: (1.) That hybridism occurs to an astonishing extent in the genus, with *Nothofagus fusca* (in a wide sense) as one parent and *N. cliffortioides* or *N. Solandri*, as the case may be, as the other parent. (2.) That *N. fusca* is made up of a number of true-breeding varieties, of which the type (called by me var. *typica*) and var. *Colensoi* are two, but there are others; and these varieties cross both amongst themselves and with the two species already mentioned. (3.) That these hybrids show

every kind of combination imaginable between the essential characteristics of the species concerned—*i.e.*, shape and size of leaf; texture of leaf; colour; toothing of margin; venation; tomentum; leaf-base; leaf-apex. (4.) The *N. Menziesii* does not hybridize. (5.) That *N. Blairii* is merely a comprehensive series of hybrids, mainly *N. cliffortioides* and × *fusca*. (6.) That *N. apiculata* is certainly another series, for the most part, but the 'type' may be a species; though, judging from Colenso's specimens, all seem taken from *one* tree. (7.) That seedlings from hybrid trees are of an extremely mixed character. (8.) That probably *N. cliffortioides* and *N. Solandri* cross; at any rate, the latter as figured in the 'Icones Plantarum' is comparatively rare.—L. COCKAYNE."

(Hook. f.)

1. **N. Menziesii** *Oerst. in Vidensk. Selsk. Skr.* v, ix (1873) 355.—A tall forest-tree 60–80 ft. or even 100 ft. high; trunk 2–5 ft. diam. or more; bark white and silvery, especially in young trees; branchlets clothed with fulvous pubescence. Leaves evergreen, shortly petiolate, $\frac{1}{3}$–$\frac{1}{2}$ in. long, broadly ovate-deltoid or rhomboid or almost orbicular, obtuse, shortly unequally cuneate at the base, thick and coriaceous, rigid, glabrous except the petiole, irregularly doubly crenate; margins thickened; stipules membranous, reddish, pubescent. Male flowers solitary, on short curved peduncles in the lower axils of the branchlets. Perianth 4–6-lobed. Stamens 6–12. Female involucres in the upper axils, 2–3-flowered. Fruiting-involucres $\frac{1}{4}$–$\frac{1}{3}$ in. long, faintly pubescent; lobes with 5–7 transverse rows of recurved linear processes tipped with an obtuse gland. Nuts puberulous, 3- or more rarely 2-winged, wings produced upwards into sharp flat points.—Fagus Menziesii *Hook. f. in Hook. Ic. Plant.* (1844) t. 652; *Raoul Choix* (1846) 42; *Hook. f. Handb. N.Z. Fl.* (1864) 249; *T. Kirk Forest Fl.* (1889) t. 89; *Cheesem. Man. N.Z. Fl.* (1906) 640.

NORTH ISLAND: Mountain forests from the Thames goldfields southwards, but rare and local to the north of the East Cape. SOUTH ISLAND: Hilly and mountain forests from Nelson to Foveaux Strait, most plentiful on the west side of the Island. Sea-level to 3500 ft. *Tawhai; Tawai; Silver-beech.* November–January.

Easily distinguished by the rigid doubly toothed leaves and recurved glandular processes on the fruiting-involucres. The wood is dark-red, strong and compact, and easily worked, but is not durable when exposed to the weather. It has been recommended for furniture, tubs and buckets, wine-casks, &c., but is not largely used at the present time.

It is worth remarking that the tips of the branches are sometimes diseased and converted into much-branched paniculate masses clothed with fulvous imbricating scales, closely resembling a paniculate inflorescence in young bud. On the under-surface of the leaves, at the junction of the main veins with the midrib, there are usually 1–3 curious fringed pits or domatia, very similar to those on the leaves of certain *Coprosmas*.

(Hook. f.)

2. **N. fusca** *Oerst. in Vidensk. Selsk. Skr.* v, ix (1873) 355.—A noble forest-tree 60–100 ft. high; trunk 4–8 ft. diam.; bark dark-brown or black in old plants, deeply furrowed, smooth and greyish-white on young trees; branchlets and petioles pubescent. Leaves evergreen, petiolate, $\frac{3}{4}$–$1\frac{1}{2}$ in. long, broadly ovate or ovate-oblong, obtuse or rarely acute, cuneate at the base, rather thin but firm, pubescent above and glandular beneath when young, glabrous when old, deeply and sharply serrate, veins conspicuous; stipules linear-oblong, caducous. Male flowers 2–3 at the end of a short curved axillary peduncle or more rarely solitary, drooping. Perianth 5-toothed, membranous, pubescent. Stamens 8–16. Female involucres

solitary in the upper axils, 2–3-flowered. Fruiting-involucres $\frac{1}{3}$–$\frac{1}{2}$ in. long, ovoid-globose, viscid-pubescent, 4-lobed; lobes furnished at the back with 3–5 transverse lamellae with entire or fringed margins. Nuts pubescent, 2–3-winged, wings produced upwards into entire or toothed points.—Fagus fusca *Hook. f. in Hook. Ic. Plant.* (1844) t. 631; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 229; *Handb. N.Z. Fl.* (1864) 249; *T. Kirk Forest Fl.* (1889) t. 90; *Cheesem. Man. N.Z. Fl.* (1906) 641.

Var. **Colensoi** *Hook. f. Fl. Nov. Zel.* i (1853) 229.—Leaves more coriaceous; teeth smaller, obtuse.—*Ic. Plant.* (1844) t. 630; *T. Kirk Forest Fl.* (1889) t. 90, f. 2. Fagus truncata *Col. in Trans. N.Z. Inst.* xxxi (1899) 280.

North Island: In forests from Mangonui and Kaitaia southwards, but local to the north of the East Cape. South Island: From Nelson to Foveaux Strait, but rare in Canterbury and eastern Otago. Sea-level to 3500 ft. *Tawhai; Tawhai-rau-nui; Red-beech.* October–December.

A magnificent tree, undoubtedly the finest representative of the genus in New Zealand, and well marked off by the comparatively thin veined leaves with sharply toothed margins. Wood dark-red, strong and compact, more durable than that of the other species, and frequently used for wharves, bridges, fencing-posts, &c.

3. **N. apiculata** *Cockayne in Trans. N.Z. Inst.* xliii (1911) 172.—A tall handsome tree 40 ft. high or more; trunk 2 ft. diam.; bark pale, smooth; branchlets pubescent. Leaves petiolate, $\frac{3}{4}$–1 in. long, oblong or ovate-oblong or elliptic-oblong, apiculate, cuneate at the base, rather thin, glabrous, quite entire or minutely or irregularly crenulate, veins not very conspicuous; stipules membranous, linear-oblong. Male flowers 1 or rarely 2 at the end of a short axillary peduncle, drooping. Perianth campanulate, membranous, 5-toothed. Stamens 8–14. Female involucres solitary in the axils of the leaves above the male inflorescence, 2–3-flowered. Fruiting-involucres $\frac{1}{4}$–$\frac{1}{3}$ in. long, narrow-ovoid, pubescent, 4-lobed; lobes with 2–4 transverse lamellae. Nuts pubescent, 2–3-winged, wings produced upwards into entire points.—Fagus apiculata *Col. in Trans. N.Z. Inst.* xvi (1884) 335; *T. Kirk Forest Fl.* (1889) t. 135; *Cheesem. Man. N.Z. Fl.* (1906) 642; *Ill. N.Z. Fl.* ii (1914) t. 182.

Var. **dubia** *Cheesem. Man. N.Z. Fl.* (1906) 642.—Leaves more coriaceous, oblong or oblong-obovate, obtuse or rarely apiculate, slightly pubescent beneath, upper half obscurely toothed or sinuate.—Fagus fusca *var.* dubia *and var.* obsoleta *T. Kirk Forest Fl.* (1889) t. 91.

North Island: Hawke's Bay—Forests near Dannevirke and Norsewood, *Colenso!* Var. *dubia:* Mungaroa and other localities near Wellington, *T. Kirk!* Tararua Mountains, *Petrie!* South Island: Marlborough, Mount Fyffe, *Cockayne.*

Very closely related to *N. fusca*, but, I think, sufficiently distinct in the smaller and narrower leaves which in the typical form are distinctly apiculate and either quite entire or very minutely crenulate, and in the smaller and narrower involucres. Var. *dubia* was placed under *N. fusca* by Kirk, and it certainly approaches var. *Colensoi* of that species; but, on the whole, appears to be nearer to *N. apiculata.*

4. **N. Blairii** *Cockayne in Trans. N.Z. Inst.* xliii (1911) 172.—A tall tree 40–60 ft. high; trunk 2–3 ft. diam.; branchlets and petioles pubescent. Leaves petiolate, spreading, $\frac{2}{3}$–$\frac{3}{4}$ in. long, $\frac{1}{3}$–$\frac{1}{2}$ in. broad, ovate, acute or apiculate, rounded at the base, quite entire, coriaceous, glabrous above, beneath clothed with fulvous appressed tomentum. Male flowers 2–3 at end of a short common peduncle. Perianth cup-shaped, 4–5-toothed. Stamens 8–15. Fruiting-involucre $\frac{1}{4}$–$\frac{1}{3}$ in. long, ovoid, glabrous, 4-lobed;

lobes with 3–4 membranous transverse lamellae. Nuts 3-winged, broad at the base, narrowed above.—Fagus Blairii *T. Kirk in Trans. N.Z. Inst.* xvii (1885) 297; *Forest Fl.* (1889) t. 57; *Cheesem. Man. N.Z. Fl.* (1906) 642.

North Island: Forests near the sources of the Wanganui River, *T. Kirk!* lower part of Waimarino Plateau, *T. F. C.* South Island: Marlborough—Mount Fyffe, *W. M. Goodall (fide Cockayne).* Nelson—Wairau Valley, Buller Valley, Little Grey River, *T. Kirk.* Otago—Five-fingers Plain, *W. N. Blair;* Lake Wakatipu and valley of the Dart, *T. Kirk.* Not uncommon in western Otago, Lake Te Anau, Lake Manapouri, &c., *H. J. Matthews!* Martin's Bay, *Buchanan.*

Differs from *N. Solandri* in the broader ovate apiculate leaves, fulvous pubescence, and 4-valved fruiting-involucre. Some specimens without flower or fruit, collected by Petrie near Arrowtown, Otago, agree with *F. Blairii* in the thick fulvous pubescence on the under-surface of the leaves, but the leaves are more oblong and obscurely toothed or sinuate, much as in *F. apiculata* var. *dubia.*

5. **N. Solandri** (*Solanderi*) *Oerst. in Vidensk. Selsk. Skr.* v, ix (1873) 355.—A lofty forest-tree 40–80 ft. high; trunk 2–5 ft. diam.; bark black and furrowed on old trees, pale and smooth on young ones; branchlets closely pubescent. Leaves evergreen, shortly petiolate, $\frac{1}{4}$–$\frac{3}{4}$ in. long, linear-oblong to elliptic-oblong, obtuse, cuneate and usually unequal-sided at the base, quite entire, coriaceous, glabrous and reticulated above, clothed with appressed greyish-white pubescence beneath, margins recurved; stipules membranous, caducous. Male flowers axillary, either solitary or 2–3 on a short common peduncle. Perianth broad and shallow, cup-shaped, shortly 4–5-toothed. Stamens 8–15. Female involucres solitary in the upper axils, sessile, 2–3-flowered. Fruiting-involucres $\frac{1}{4}$ in. long, ovoid, glabrous or pubescent, usually 3-lobed; lobes with three membranous transverse lamellae. Nuts 2–3-winged, broad at the base, narrowed above.—Fagus Solandri *Hook f. in Hook. Ic. Plant.* (1844) t. 639; *Raoul Choix* (1846) 42; *Hook f. Fl. Nov. Zel.* i (1853) 230; *Handb. N.Z. Fl.* (1864) 250; *T. Kirk Forest Fl.* (1889) t. 56; *Cheesem. Man. N.Z. Fl.* (1906) 643.

North and South Islands: Forests from the East Cape to the south of Otago, usually in hilly or mountain districts. Sea-level to 2500 ft. *Tawhai; Tawhai-rauriki; Black-beech.* November–December.

Wood pale-red, often streaked with black, not durable unless taken from fully mature trees. Young trees often have the leaves distichously arranged, with the under-surface glabrous or nearly so.

6. **N. cliffortioides** *Oerst. in Vidensk. Selsk. Skr.* v, ix (1873) 355.—A small tree, usually from 20 to 40 ft. high, rarely more, with a trunk 1–2 ft. diam., in alpine localities often dwarfed into a much-branched bush 5–12 ft. high. Branches spreading, often distichous, especially in young trees; branchlets densely pubescent. Leaves shortly petiolate, distichous, $\frac{1}{6}$–$\frac{2}{3}$ in. long, ovate-oblong or ovate or ovate-orbicular, acute or subacute, rarely obtuse, always broadest at the unequally rounded or almost cordate base, quite entire, very coriaceous, glabrous and reticulated above, more or less clothed with greyish-white appressed hairs beneath; margins thickened, often recurved; stipules membranous, caducous. Male flowers axillary, solitary or in pairs on very short peduncles, often very abundantly produced. Perianth broad, cup-shaped, shortly 4–5-toothed. Stamens 8–15. Female involucres solitary and sessile in the upper axils, 2–3-flowered. Fruiting-involucres $\frac{1}{6}$–$\frac{1}{4}$ in. long, ovoid, pubescent, 3-lobed;

lobes with two or three transverse fringed lamellae. Nuts 2–3-winged, ovoid, acute.—*Cockayne Veg. N.Z.* (1921) t. 55, 56. Fagus cliffortioides *Hook. f. in Hook. Ic. Plant.* (1844) t. 673 *and* t. 816B; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 230; *Handb. N.Z. Fl.* (1864) 250; *T. Kirk Forest Fl.* (1889) tt. 101, 101A; *Cheesem. Man. N.Z. Fl.* (1906) 643.

North Island: Mountain districts from the East Cape and Tongariro southwards South Island: Abundant in the mountains throughout, usually forming the greater portion of the subalpine forests. Altitudinal range from 2000 ft. to 4500 ft., but descending to sea-level in one or two localities in Westland, and in the sounds on the south-west coast of Otago. *Tawhai-rauriki; Mountain-beech.* December–January.

Closely allied to *N. Solandri*, but much smaller, with the leaves truly ovate, broadest at the base, and usually acute at the tip. Wood very similar to that of *N. Solandri*.

Family XXVII. **MORACEAE.**

Trees or shrubs, rarely herbs; usually with milky sap. Leaves alternate, seldom opposite, stipules present. Flowers monoecious or dioecious, generally small and inconspicuous, arranged in heads, spikes, or catkins. Perianth 3–4-lobed or -partite; lobes valvate or imbricate. Stamens usually as many as the perianth-lobes; filaments inflexed in bud. Ovary almost always superior, 1-celled; ovule solitary, pendulous. Style terminal or subterminal. Fruit small, 1-seeded, dry or rarely succulent.

As defined in the "Pflanzenfamilien," this is a family of 50 or 60 genera, probably containing 850 species, most of which are tropical. It includes quite a large number of useful plants, only a few of which can be mentioned here. Of edible species, the fig, mulberry, and bread-fruit are the most important. Of fibre-plants, the common hemp and the paper-mulberry are well-known species. Several species of *Ficus*, and notably *F. elastica*, yield indiarubber. *Ficus indica* is the well-known banyan. The upas-tree (*Antiaris toxicaria*) is highly poisonous. The single New Zealand genus is also found in eastern Polynesia.

1. **PARATROPHIS** Blume. 1852.

Trees with milky juice. Leaves alternate, shortly petiolate, crenate or almost entire, penninerved; stipules small, lateral, caducous. Flowers dioecious, in axillary or rarely terminal solitary or geminate spikes. Male flowers: Numerous, usually closely placed. Perianth small, 4-partite; segments broad, obtuse, concave, imbricate. Stamens 4; filaments inflexed in bud; anthers didymous, 2-celled. Rudimentary ovary turbinate. Female flowers: Few and lax, or numerous and dense. Perianth very small, 4-partite; segments unequal, closely imbricate. Ovary straight, sessile, exserted, 1-celled; style deeply 2-partite; ovule solitary, pendulous. Fruit drupaceous, seated on the slightly enlarged persistent perianth, globose or ovoid, tipped by the short style; exocarp thin, fleshy; endocarp crustaceous. Seed subglobose; albumen scanty; cotyledons broad, foliaceous, conduplicate.

A small genus of 10 species, 3 of which are found in New Zealand, 5 in the Pacific islands, and 2 in the Philippines.

Leaves $\frac{1}{3}$–$1\frac{1}{2}$ in. Female spikes $\frac{1}{4}$–$\frac{1}{2}$ in., 3–8-flowered. Drupes 1–3 ripening on each spike, $\frac{1}{6}$ in. diam.	1. *P. microphylla.*
Leaves $1\frac{1}{2}$–$3\frac{1}{2}$ in. Female spikes $\frac{1}{2}$–1 in., 8–25-flowered. Drupes usually many ripening on each spike, $\frac{1}{4}$ in. diam.	2. *P. opaca.*
Leaves 4–8 in., entire. Female spikes 2–4 in., many-flowered; flowers in 2 rows on each side of the rhachis. Drupe $\frac{1}{3}$ in. diam.	3. *P. Smithii.*

× P. microphylla/opaca allan, Genetica 1925. 7:290

(Raoul) Bruce 1916 or 17 : 639 ?

1. **P. microphylla** /*Cockayne Veg. N.Z.* (1921) 355.—A tree 15–40 ft. high, with a trunk 9–24 in. diam.; bark grey or almost white, rough with raised lenticels; branches numerous, crowded, glabrous or pubescent; those of young plants long and slender, flexuous, often interlaced, pubescent or setose at the tips, bark dark-brown. Leaves of young plant remote, $\frac{1}{3}$–$\frac{3}{4}$ in. long, broadly obovate to oblong-obovate, acute or obtuse, cuneate at the base, rather membranous, glabrous or pubescent, serrate, often irregularly lobed or almost pinnatifid; of mature trees $\frac{1}{3}$–$1\frac{1}{2}$ in. long, oblong-ovate or oblong-obovate to elliptic, obtuse or acute, crenate or crenate-dentate, coriaceous, dark-green, prominently reticulate. Male spikes $\frac{1}{3}$–1 in. long, shortly pedunculate, cylindric. Flowers closely packed, minute, sessile, intermixed with peltate scales. Perianth-segments rounded, margins ciliate. Stamens exserted. Female spikes $\frac{1}{4}$–$\frac{1}{2}$ in. long, 3–8-flowered. Flowers lax, very minute, intermixed with peltate scales. Perianth-segments appressed to the ovary, the 2 outer rather smaller. Drupe globose, small, red, $\frac{1}{6}$ in. diam., usually 1 and seldom as many as 3 ripening on each spike.—P. heterophylla *Blume Mus. Bot. Lugd. Bat.* ii (1852) 81; *Cheesem. Man. N.Z. Fl.* (1906) 632; *Ill. N.Z. Fl.* ii (1914) t. 180. Epicarpurus microphyllus *Raoul Choix* (1846) 14, t. 9; *Hook. f. Handb. N.Z. Fl.* (1864) 251. Trophis opaca *Hook. f. Fl. Nov. Zel.* i (1853) 224 (*in part*). Taxotrophis microphylla *F. Muell. Fragm. Phyt. Austral.* vi (1868) 193.

North and South Islands: Not uncommon in lowland forests throughout. *Turepo; Milk-tree.* October–February.

Abounding in milky sap, which is said to be palatable. The wood is dense and heavy, but not durable. The spikes are often diseased, and converted into large much-branched panicles densely clothed with small imbricating bracts, the flowers being altogether aborted.

(B.+S. ex Hook.f.)

2. **P. opaca**/*Britton and Rendle in Journ. Bot.* (1907) 74.—A small tree 15–25 ft. high, glabrous or the young branches pubescent; bark brown. Leaves usually close-set, spreading, $1\frac{1}{2}$–$3\frac{1}{2}$ in. long, ovate-oblong or elliptic-oblong, obtuse or acute, coriaceous, glabrous, obtusely crenate or crenate-dentate, veins finely reticulate. Spikes solitary or geminate or rarely 3 together, axillary, rarely terminal, pedunculate. Males 1–2 in. long, cylindrical, densely many-flowered; flowers intermixed with peltate scales. Perianth rather larger than in *P. heterophylla.* Female spikes $\frac{1}{2}$–1 in. long; flowers 8–25 or more, distichous, rhachis compressed. Drupe broadly ovoid, red, $\frac{1}{4}$ in. diam., always several and often many ripening on each spike.—P. Banksii *Cheesem. Man. N.Z. Fl.* (1906) 633. P. heterophylla *var.* elliptica *T. Kirk in Trans. N.Z. Inst.* xxix (1897) 500, t. 46. Trophis opaca *Banks and Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 224 (*in part*).

See Bruce 1916 p. 639.

North Island: Usually near the sea. Bay of Islands, *Colenso!* Whangarei Heads and Hen and Chicken Islands, *T. F. C.;* Great Barrier Island, Omaha, *T. Kirk!* Cuvier Island, *T. F. C.;* Mayor Island, *Dr. Thilenius;* Cabbage Bay, *Adams!* East Cape district, *Banks* and *Solander, Bishop Williams! Petrie!* Cook Strait, *T. Kirk!* Wainuiomata to Orongorongo, Cook Strait, *B. C. Aston!* Stephen Island, *H. H. Travers!* South Island: Motuaro Island (Queen Charlotte Sound), *Banks* and *Solander! J. H. Macmahon!*

This is separated from *P. microphylla* by the much larger leaves, longer spikes, more numerous female flowers, and much larger and more numerous drupes; and in its extreme form has a very distinct appearance. Intermediate states, however, are by no means uncommon.

3. **P. Smithii** *Cheesem. in Trans. N.Z. Inst.* xx (1888) 148.—A perfectly glabrous shrub or small tree 6–15 ft. high, with copious milky juice; branches long, slender, straggling, often flexuous and interlaced; bark dark-brown, rough with raised lenticels. Leaves 4–8 in. long, ovate-oblong or elliptic-oblong, obtuse or obtusely acuminate, rounded or obliquely cordate at the base, quite entire, dark-green, coriaceous; veins conspicuous, reticulated; stipules lanceolate, caducous. Spikes solitary or geminate, axillary or from the branches below the leaves, 2–5 in. long. Males cylindric, densely many-flowered; flowers intermixed with peltate scales. Perianth $\frac{1}{8}$ in. diam.; segments rounded, spreading, pubescent externally. Females many-flowered, the flowers minute, densely packed in 2 irregular rows on each side of the flattened rhachis, intermixed with peltate scales. Perianth-segments rounded, obtuse, closely appressed to the ovary, the 2 outer rather smaller than the others. Ovary conic, exserted. Style deeply 2-partite. Drupe globose, bright-red, $\frac{1}{3}$ in. diam.—*Man. N.Z. Fl.* (1906) 633.

North Island: Three Kings Islands, abundant, *T. F. C.*

Easily recognized by the large entire leaves and long many-flowered female spikes, with the flowers distichously arranged in 2 rows on each side of the rhachis.

Family XXVIII. **URTICACEAE.**

Herbs, shrubs, or trees, of very diversified habit and foliage; sap watery, very rarely milky. Leaves alternate or opposite, entire or toothed or more rarely divided; stipules present. Flowers unisexual, small and inconspicuous, cymose or fascicled or capitate, sometimes crowded on a variously shaped receptacle with or without an involucre. Perianth simple, herbaceous, of 4–5 equal or unequal lobes or segments, imbricate or valvate in bud, in the female flowers often smaller and with fewer segments, rarely absent. Stamens equal and opposite to the segments; filaments often inflexed in bud, uncoiling elastically when the flower opens; anthers 2-celled, dehiscing longitudinally. Ovary superior or rarely inferior, 1-celled; style terminal or lateral; ovule solitary. Fruit dry or fleshy, naked or enclosed in or adnate to the somewhat accrescent perianth. Seed erect; albumen present or very rarely wanting. Embryo straight, axile; radicle superior.

A family of about 45 genera and 500 species, the great majority of which are purely tropical. With the exception of a few fibre-plants like the Rhea (*Boehmeria nivea*) the family contains few species of economic value. Of the 5 indigenous genera, *Urtica* and *Parietaria* are widely spread in most temperate and tropical countries; *Elatostema* and *Boehmeria* are mainly tropical; while *Australina* is found in Australia and South Africa.

Herbs with stinging hairs. Leaves opposite. Female perianth 4-partite	1. Urtica.
Herbs. Leaves alternate. Flowers crowded on a fleshy discoid receptacle	2. Elatostema.
Trees. Leaves 3-nerved. Female perianth tubular, enclosing the fruit	3. Boehmeria.
Herbs, without stinging hairs. Leaves alternate. Flowers in involucrate clusters. Female perianth tubular. Stigma tufted	4. Parietaria.
Herbs, without stinging hairs. Leaves alternate. Flowers not involucrate. Female perianth tubular. Stigma linear	5. Australina.

1. **URTICA** Linn. 1735 Syst-1

Annual or perennial herbs or small shrubs, more or less armed with stinging hairs. Leaves opposite, petiolate, toothed or lobed, 3–7-nerved; stipules lateral, free or connate. Flowers small, green, monoecious or dioecious, in clusters arranged in axillary simple or branched racemes or panicles. Male flowers: Perianth deeply 4-partite; segments ovate or rounded, concave. Stamens 4, inflexed in bud. Rudimentary ovary cupuliform. Female flowers: Perianth deeply 4-partite; the 2 outer segments smaller than the inner. Ovary straight, ovoid; stigma sessile or nearly so, penicillate; ovule solitary, erect, orthotropous. Achene ovoid or oblong, compressed, enclosed in the persistent perianth. Seed erect; albumen scanty; cotyledons rounded.

Species 30 to 35, widely spread in the temperate and subtropical regions of both hemispheres, rarer in the tropics. One of the New Zealand species extends to Australia, the remaining three are endemic.

Shrubby, 3–10 ft. high. Stinging hairs copious, long, rigid. Leaves 2–5 in., narrow ovate-triangular to lanceolate	1. *U. ferox.*
Herbaceous, stout, 1–3 ft. high, glabrous or nearly so. Stinging hairs few, weak. Leaves 3–6 in., ovate- or orbicular-cordate ..	2. *U. australis.*
Herbaceous, stout, 1 ft. high, pubescent with greyish-white hairs. Leaves 2–3 in., broadly ovate	3. *U. aucklandica.*
Dioecious, stout, subcoriaceous, everywhere clothed with copious stinging hairs. Leaves broad	4. *U. aspera.*
Monoecious, slender, thin; stinging hairs few. Leaves broad ..	5. *U. incisa.*
Tall, slender, stems often flexuous. Leaves linear or linear-lanceolate	6. *U. linearifolia.*

1. **U. ferox** *Forst. f. Prodr.* (1786) n. 346.—A slender much-branched shrub, sometimes 6–10 ft. high with a woody trunk 3–4 in. diam. at the base, but usually from 2 to 5 ft.; stinging hairs copious, long, rigid, $\frac{1}{6}$–$\frac{1}{4}$ in. long; branchlets, petioles, and under-surface of leaves more or less finely pubescent. Leaves on long slender petioles; blade 2–5 in. long, narrow ovate-triangular to lanceolate-triangular, acuminate, broadest at the base which is truncate or rounded or cordate and often lobed or hastate, thin and membranous; margins deeply and coarsely toothed, the teeth ending in a long rigid bristle; stipules interpetiolar, entire. Flowers dioecious, in axillary racemiform panicles 1–2 in. long. Perianth densely pubescent, females smaller than the males. Nut ovoid, compressed, about $\frac{1}{20}$ in. long.—*A. Rich. Fl. Nouv. Zel.* (1832) 354; *A. Cunn. Precur.* (1838) n. 333; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 225; *Handb. N.Z. Fl.* (1864) 251; *Cheesem. Man. N.Z. Fl.* (1906) 634.

North and South Islands: Ngamahanga, near Kawakawa, Bay of Islands, *T. H. Trevor!* Marokopa, *E. Phillips Turner!* Ongarue, *T. F. C.;* Taumarunui, *Cockayne;* Makatote, *H. B. Matthews!* Patetere Range, south of Te Aroha, *Downard!* Paeroa Range, near Waiotapu, *A. Allison!* East Cape and Kawhia southwards to eastern Otago, not common. *Tree-nettle; Ongaonga.* Sea-level to 2000 ft.

A very distinct species, easily recognized by the large size, woody stems, and copious stipitate stinging hairs.

2. **U. australis** *Hook. f. Fl. Antarct.* i (1844) 68.—Stems 1–3 ft. high, erect or decumbent at the base, stout, succulent, glabrous or sparingly clothed with short white hairs; stinging hairs few, weak, chiefly clustered at the nodes. Leaves opposite, the upper sometimes ternate; blade 3–6 in. long or even more, broadly ovate- or orbicular-cordate, acute, coarsely toothed or crenate, rather fleshy, 5–7-nerved, glabrous or sparsely pubescent

or setose; petiole stout, 1–4 in. long; stipules interpetiolar, large, bifid. Racemes or panicles simple or branched, axillary, longer or shorter than the petioles, the lower male and the upper female, but both sexes occasionally mixed in the same panicle. Male perianth about $\frac{1}{12}$ in. diam., glabrous or nearly so; female rather smaller. Nut ovoid, compressed, smooth, rather shorter than the persistent perianth.—*Fl. Nov. Zel.* i (1853) 225; *Handb. N.Z. Fl.* (1864) 251; *Cheesem. Man. N.Z. Fl.* (1906) 635.

North Island: "Southern extreme, *Bidwill*" (Handbook). Chatham Islands: *H. H. Travers! F. A. D. Cox* and *Cockayne!* Stewart Island: Not seen on the main island, but not uncommon on Dog Island, Centre Island, *T. Kirk!* and Long Island, *Poppelwell!* and probably other islets in Foveaux Strait. Auckland, Campbell, and Antipodes Islands: *Hooker, T. Kirk, Cockayne, B. C. Aston! R. M. Laing! J. S. Tennant.* December–March.

Remarkable for its stout succulent habit and large leaves. Although reported from the North Island in the Handbook, on the authority of Bidwill, of late years no New Zealand botanist has met with it on any part of the mainland of either the North or South Island.

3. **U. aucklandica** *Hook. f. Fl. Antarct.* i (1844) 68.—A rigid herb, everywhere pubescent with short greyish-white hairs. Stems stout, erect, angled, about 1 ft. high; stinging hairs few, chiefly clustered at the thickened nodes. Leaves opposite, spreading, 2–3 in. long, $1\frac{1}{2}$–$2\frac{1}{2}$ in. broad, broadly ovate, acute, usually cordate at the base, rather coriaceous, many-nerved, coarsely serrate or dentate; petioles stout, $\frac{1}{2}$–1 in. long; stipules rather large, interpetiolar, 2-fid or 2-partite. Male flowers alone seen, in short axillary spikes. Perianth-segments 4, rounded, concave, setose on the back. Stamens 4; filaments short.—*Handb. N.Z. Fl.* (1864) 251; *Cheesem. Man. N.Z. Fl.* (1906) 635.

Auckland Islands: Near the sea-beach at the margin of woods, rare, *Hooker.*

I have seen no specimens of this, and the above description has been compiled from that given in the "Flora Antarctica." It appears to be very close to *U. australis*, differing chiefly in the smaller size and more rigid habit, and in the dense greyish-white pubescence. As it has not been gathered by any one since its original discovery by Hooker in 1840, and as his specimens were immature and imperfect, it may be safely regarded as a state of *U. australis.*

4. **U. aspera** *Petrie in Trans. N.Z. Inst.* li (1919) 107.—Rather stout, erect or decumbent at the base, much branched, 1–$1\frac{1}{2}$ ft. high, densely clothed in all its parts with stiff white stinging hairs. Leaves opposite, variable in size and shape; petioles stout, often exceeding the blades in length; blades $1\frac{1}{2}$–$2\frac{1}{2}$ in. long, $\frac{3}{4}$–$1\frac{1}{2}$ in. broad, ovate or ovate-triangular, coarsely and sometimes deeply serrate, acute, subcoriaceous; stinging hairs plentiful on most of the main veins. Inflorescence dioecious; male spikes geminate or single in the upper axils, rather long; the flowers arranged in small distant glomerules; female spikes simple or branched; flowers numerous, crowded. Nuts broadly ovoid; fruiting-perianth not enlarged.

South Island: Marlborough—Head of Awatere Valley, *Cockayne!* Dee Valley, Clarence basin, *B. C. Aston!* Otago—Firewood Creek, near Cromwell; Sowburn, Maniototo County, *Petrie;* vicinity of Clyde, *Cockayne,* abundant. 1500–3000 ft.

Very close to *U. incisa*, but stouter and more coriaceous; with all its parts, including the inflorescence, densely covered with stinging hairs. The flowers are dioecious, whereas they are monoecious in *U. incisa.* Dr. Cockayne informs me that it has long underground stems and that by their aid it is rapidly spreading in certain parts of Central Otago.

5. **U. incisa** *Poir. Encycl. Suppl.* iv (1817) 224.—Stems slender, erect or decumbent at the base, much or sparingly branched or simple, sparsely clothed with weak stinging hairs but otherwise glabrous, 1–2 ft. high, rarely more. Leaves on long slender petioles, very variable in size and shape; blade ½–2½ in. long, broadly ovate-deltoid to lanceolate, acute or acuminate, cordate or truncate or cuneate at the base, deeply and acutely toothed, membranous; stinging hairs few, weak. Spikes or racemes single or geminate in the axils of the upper leaves, often branched, longer or shorter than the petioles, the lower male and the upper female, or inflorescence altogether monoecious. Male perianth $\frac{1}{15}$ in. diam., glabrous or nearly so; female perianth much smaller when in flower but enlarging as the fruit ripens. Nut ovoid, compressed, rather longer than the persistent slightly enlarged perianth.—*Hook. f. Handb. N.Z. Fl.* (1864) 251; *Benth. Fl. Austral.* vi (1873) 190; *Cheesem. Man. N.Z. Fl.* (1906) 635. U. lucifuga *Hook. f. in Hook. Lond. Journ. Bot.* vi (1847) 285; *Fl. Nov. Zel.* i (1853) 225.

North and South Islands: Not uncommon in shaded places, from the North Cape to Foveaux Strait. Sea-level to 4000 ft. Flowers spring and summer.

Also common in Australia and Tasmania, and very near to the northern *U. dioica* (which is sparingly naturalized in New Zealand), principally differing in the more slender habit, in not being conspicuously pubescent between the stinging hairs, and in the usually shorter spikes.

6. **U. linearifolia** *Cockayne in Trans. N.Z. Inst.* xlvii (1915) 111.—Stems weak, slender, erect or flexuose, much or sparingly branched, more or less clothed with weak stinging hairs but otherwise glabrous, 1–3 ft. high. Leaves on slender petioles, variable in size and shape, but always much narrower than those of *U. incisa;* blade ½–4 in. long, ⅛–½ in. wide, lanceolate to linear-lanceolate or linear, coarsely or finely toothed, usually cuneate at the base. Spikes much shorter than those of *U. incisa,* often reduced to axillary glomerules. Inflorescence much as in *U. incisa,* but flowers smaller. Nuts brown, ovoid, persistent after the perianth has fallen.—U. lucifuga *var.* linearifolia *Hook. f. Fl. Nov. Zel.* i (1853) 225. U. incisa *var.* linearifolia *Cheesem. Man. N.Z. Fl.* (1906) 636.

TNZI. 65:231

North Island: Lake Papaitonga, near Levin, *B. C. Aston;* Makurerua Swamp, *Cockayne.* South Island: Clarence Valley, *T. F. C.;* various localities in eastern Otago, *Petrie!* Humboldt Mountains, *Cockayne.* Sea-level to 4000 ft. December–February.

2. **ELATOSTEMA** Forst. 1776. nom. cons.

Herbs, sometimes woody at the base. Leaves distichous, alternate, or if opposite one of each pair much smaller than the other, sessile or nearly so, oblique and unequal-sided; stipules lateral or intrapetiolar. Flowers very minute, densely crowded in axillary sessile or peduncled unisexual usually involucrate receptacles; involucral bracts broadly oblong or ovate, nearly free or confluent below. Male flowers: Perianth 4–5-partite; segments membranous or hyaline, often spurred or tubercled on the back. Stamens 4–5, inflexed in bud. Rudimentary ovary minute. Female flowers: Perianth of 3–5 very minute segments or altogether wanting. Stamens imperfect. Ovary straight; stigma sessile, penicillate; ovule erect. Achene minute, compressed, ovoid or ellipsoid, smooth or rarely ribbed. Seed erect; albumen usually wanting; cotyledons ovate.

About 80 species are known, for the most part natives of tropical Asia and Africa, but the genus extends northwards to Japan, and southwards to New Zealand.

1. **E. rugosum** *A. Cunn. Precur.* (1838) n. 335.—Stems stout, succulent, decumbent or prostrate and rooting at the base, erect above, sparingly branched, 1–5 ft. high. Leaves alternate, 4–10 in. long, obovate-lanceolate or lanceolate, acuminate, curved, unequal-sided, auricled and semi-amplexicaul at the sessile base, sharply serrate, membranous, rugose, pubescent with minute rigid hairs on both surfaces; stipules lanceolate, membranous, deciduous. Receptacles monoecious, solitary in the axils of the leaves, sessile or shortly pedunculate, depressed-hemispherical, often lobed, $\frac{1}{4}$–$\frac{1}{2}$ in. diam. Males: Bracts broad, glabrous or puberulous. Flowers very numerous, pedicelled, hidden among the broad membranous bracteoles. Perianth 4-partite; segments abruptly acuminate, hyaline. Females with the bracts narrower and more pubescent. Bracteoles linear-spathulate, ciliate. Flowers almost sessile; perianth very minute, of 4 hyaline segments. Stigma penicillate. Achene minute, ovoid, smooth.—*Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 227; *Handb. N.Z. Fl.* (1864) 253; *Cheesem. Man. N.Z. Fl.* (1906) 636.

North Island: Damp shaded ravines from the North Cape southwards to the middle of Wellington Province, but local to the south of the Waikato River. Sea-level to 2000 ft. *Parataniwha.* Flowers spring and summer.

The heads or receptacles are usually described as unisexual, but it is not uncommon to find both sexes mixed in the same head.

3. **BOEHMERIA** Jacq. 1760.

Shrubs or small trees. Leaves alternate or opposite, toothed, 3-nerved; stipules usually free, deciduous. Flowers monoecious or dioecious, in small globose glomerules; glomerules axillary, either solitary or spiked or racemed or panicled. Male flowers: Perianth 3–5-lobed or -partite; segments valvate. Stamens 3–5, inflexed in bud. Rudimentary ovary clavate or globose. Female flowers: Perianth tubular, compressed or ventricose, mouth often contracted, 2–4-toothed. Ovary included, sessile or stipitate; stigma filiform, persistent; ovule solitary, erect. Achene closely invested by the persistent perianth, crustaceous. Seed albuminous; cotyledons ovate or elliptic.

Species about 60, widely spread through the tropics of both hemispheres.

1. **B. dealbata** *Cheesem. in Trans. N.Z. Inst.* xxiv (1892) 410.—A small tree 8–25 ft. high; branches terete, pubescent with minute appressed hairs. Leaves alternate, 3–6 in. long, ovate or ovate-lanceolate, acuminate, rounded at the base, rarely slightly cordate, obtusely serrate, prominently 3-nerved and with the secondary veins also strongly marked, green and glabrous and rugulose above, white and hoary beneath; petioles stout, $\frac{3}{4}$–2 in. long, grooved on the upper surface. Flowers minute, in small axillary sessile glomerules, which are either unisexual or androgynous. Male flowers: Perianth deeply 4-partite; segments oblong-ovate, acuminate, clothed with erect hairs. Stamens exserted. Females: Perianth tubular, dilated below, contracted at the 2-toothed mouth. Stigma exserted, long, filiform, hirsute. Fruiting-perianth much compressed, broadly winged. Achene very minute, ovoid, quite smooth.—*Man. N.Z. Fl.* (1906) 637; *Ill. N.Z. Fl.* ii (1914) t. 181.

Kermadec Islands: Sunday Island, not uncommon at low elevations, *T. F. C., W. R. B. Oliver!* Flowers most of the year.

Nearly intermediate in characters between the Norfolk Island *B. australis* and the Lord Howe Island *B. calophleba,* but apparently distinct from both.

Skottsb. Die Flora der Osterinseln 1937: 9.

4. **PARIETARIA** [Tourn.] Linn 1735.

Annual or perennial herbs. Leaves alternate, petiolate, quite entire, 3-nerved; stipules wanting. Flowers polygamous, in axillary cymes or glomerules, sessile, bracteate. Male flowers (often hermaphrodite): Perianth deeply 3–4-partite; segments valvate. Stamens 3–4, inflexed in bud. Female flowers: Perianth tubular at the base, 3–4-lobed. Ovary free within the perianth; stigma recurved, penicillate; ovule solitary, erect. Achene enclosed in the variously enlarged persistent perianth, crustaceous. Seed albuminous; cotyledons oblong or ovate.

A small genus of 7 or 8 species, generally distributed in both temperate and tropical regions. The single New Zealand species has almost the range of the genus.

1. **P. debilis** *Forst. f. Prodr.* (1786) n. 387.—A slender flaccid more or less pubescent diffusely branched annual herb 6–18 in. high. Leaves on long slender petioles; blade $\frac{1}{2}$–$1\frac{1}{2}$ in. long, broadly ovate or ovate-cordate, obtuse or obtusely acuminate, thin and membranous, quite entire, green on both surfaces, 3-nerved from the base. Cymes 3–7-flowered, almost contracted into sessile clusters; bracts linear, shortly united at the base. Hermaphrodite (or male) flowers usually in the fork of the cyme; perianth almost unchanged in fruit. Females flowers lateral; perianth evidently enlarged in fruit. Achene very minute, dark-brown, quite smooth.—*A. Rich. Fl. Nouv. Zel.* (1832) 354; *Hook. f. Fl. Nov. Zel.* i (1853) 226; *Handb. N.Z. Fl.* (1864) 252; *Benth. Fl. Austral.* vi (1873) 188; *Cheesem. Man. N.Z. Fl.* (1906) 638. Urtica debilis *Endl. Prodr. Fl. Insl. Norfl.* (1833) 37; *A. Cunn. Precur.* (1836) n. 334; *Raoul Choix* (1846) 42.

Kermadec Islands, North and South Islands: Abundant as far south as middle Otago. Sea-level to 2500 ft. Flowers spring and summer.

5. **AUSTRALINA** Gaud. 1826 in Freyc. Voy. Bot. 575.

Diffuse or creeping annual or perennial herbs. Leaves alternate, petiolate, crenate-toothed or almost entire; stipules lateral, free. Flowers monoecious, in few-flowered axillary glomerules; glomerules unisexual or androgynous. Male flowers: 1–5 together at the summit of a common peduncle. Perianth irregularly bilabiate, the outer lip inflexed in bud. Stamen solitary. Rudimentary ovary wanting. Female flowers solitary or few together, sessile. Perianth ovoid-tubular, mouth contracted and obscurely toothed. Ovary free within the perianth; stigma linear, villous; ovule erect from the base. Achene enclosed in the persistent perianth; pericarp thin, shining. Seed with scanty albumen; cotyledons ovate.

A small genus of 6 species, 2 found in Australia, 1 of them extending to New Zealand, and 4 natives of South Africa and Abyssinia.

1. **A. pusilla** *Gaud. in Freyc. Voy. Bot.* (1826) 505.—Stems very slender, creeping and rooting, much and often intricately branched, 3–12 in. long, more or less pubescent. Leaves $\frac{1}{6}$–$\frac{1}{2}$ in. long, broadly ovate or orbicular or broader than long, rounded at the tip, cuneate or almost truncate at the base, obtusely crenate, thin and membranous, pubescent on both surfaces; petiole as long or longer than the blade. Male flowers 2–3 together or solitary; peduncle variable in length, sometimes exceeding the petiole. Perianth irregularly bilabiate, green, membranous, hispid. Stamen large,

exserted. Female flowers solitary or 2–3 together, each on a very short peduncle or sessile, in the same or in a different axil to the male inflorescence. Perianth very minute, flask-shaped, 2–3-toothed at the constricted mouth. Style exserted, villous.—*Hook. f. Handb. N.Z. Fl.* (1864) 252; *Benth. Fl. Austral.* vi (1873) 189; *Cheesem. Man. N.Z. Fl.* (1906) 639. A. novae-zealandiae *Hook. f. Fl. Nov. Zel.* i (1853) 226. A. hispidula *Col. in Trans. N.Z. Inst.* xviii (1886) 266.

North and South Islands: Dark shaded woods from Hokianga and the Bay of Islands to Foveaux Strait, but often very local. Sea-level to 1000 ft.

Family XXIX. **PROTEACEAE.**

Shrubs or trees, rarely herbs. Leaves usually alternate, very rarely opposite or whorled, generally hard and coriaceous, entire or toothed or variously divided; stipules wanting. Flowers usually hermaphrodite, inflorescence various. Perianth inferior, regular or irregular; segments 4, valvate, at first cohering into a cylindric tube, at length separating and becoming revolute. Stamens 4, inserted on the perianth-segments and opposite to them; filaments short; anthers erect, adnate, 2-celled, introrse. Hypogynous glands 4, alternating with the stamens. Ovary superior, 1-celled, often oblique; style terminal, variously thickened and enlarged at the top; stigma terminal or lateral; ovules solitary or geminate or many. Fruit either an indehiscent nut or drupe, or a dehiscent coriaceous or woody follicle, more rarely a 2-valved capsule. Seeds exalbuminous; embryo straight, with fleshy cotyledons, radicle inferior.

A large and well-marked family, chiefly found in Australia and South Africa, but extending to the Pacific islands and tropical Asia on the one side and South America on the other; absent in Europe, North Asia, and North America. Genera about 50; species estimated at 950. Several species are cultivated for ornamental purposes, but few possess any useful properties. Of the two indigenous genera, *Knightia* has two species in New Caledonia, while *Persoonia* is largely developed in Australia. The meagre representation of the family in New Zealand, compared with its abundance in Australia, is a very curious and almost inexplicable feature of the flora.

Small spreading tree. Leaves entire. Fruit fleshy .. .. 1. Persoonia.
Tall fastigiate tree. Leaves serrate. Fruit a woody follicle .. 2. Knightia.

1. **PERSOONIA** Smith. 1795. Tr. Linn Soc. 4: 215.

Shrubs or small trees. Leaves entire, alternate or sometimes almost whorled. Flowers small, hermaphrodite, yellowish or white, solitary and axillary, or in axillary or terminal racemes. Perianth regular, constricted above the base or cylindrical; segments ultimately separating to the base or nearly so, upper portion revolute. Stamens affixed at or below the middle of the perianth-segments; filaments short; anthers usually all perfect, oblong or linear. Hypogynous scales 4, small. Ovary stipitate; style short and thick, or elongated and filiform; stigma terminal; ovules 2 or rarely 1, orthotropous, pendulous from the top of the cell. Fruit a drupe, either 1-celled and 1-seeded, or obliquely 2-celled and 2-seeded; exocarp more or less succulent; endocarp thick and hard.

Species about 60, all confined to Australia except the present one, which is endemic in the North Island of New Zealand.

1. **P. Toru** *A. Cunn. in Bot. Mag.* sub. t. 3513.—A handsome closely branched tree 15 to 30 or 40 ft. high; trunk 6–18 in. diam.; branchlets woody, terete, glabrous or the younger ones minutely puberulous. Leaves alternate, 4–8 in. long, narrow linear-lanceolate, acute or apiculate or rarely obtuse, gradually narrowed into a short petiole, quite entire, very thick and coriaceous, glabrous, smooth and polished on both surfaces, veins very obscure. Racemes axillary, strict, erect, 6–12-flowered, everywhere clothed with ferruginous pubescence. Perianth yellowish-brown, shortly pedicelled, $\frac{1}{4}$–$\frac{1}{3}$ in. long, pubescent externally. Ovary almost sessile, glabrous; style short, thick, not reaching the anthers; stigma oblique. Drupe oblong, reddish, $\frac{1}{2}$–$\frac{2}{3}$ in. long, 1- or 2-celled, with a single seed in each cell.—*Cheesem. Man. N.Z. Fl.* (1906) 605; *Ill. N.Z. Fl.* ii (1914) t. 170; P. Tora *A. Cunn. Precur.* (1838) n. 349; *Raoul Choix* (1846) 42. P. Toro *Hook. f. Fl. Nov. Zel.* i (1853) 219; *Handb. N.Z. Fl.* (1864) 241; *T. Kirk Forest Fl.* (1889) t. 74.

North Island: Not uncommon in woods from the North Cape to Rotorua and the East Cape. Sea-level to 2800 ft. *Toru*; *Toro*. October–November.

The specific name was given as "Toru" in Cunningham's original description in the "Botanical Magazine," and according to Mr. Colenso this is the proper spelling of the Maori name. It was, however, changed to "Tora" in Cunningham's subsequently published "Precursor," and was again altered to "Toro" by Sir J. D. Hooker. The wood is dark-red and prettily figured, and is occasionally used for inlaying and ornamental cabinetwork.

2. KNIGHTIA R. Br. 1810. nom. cons.

Trees or shrubs. Leaves alternate, coriaceous, coarsely toothed or entire. Flowers hermaphrodite, regular, arranged in axillary or terminal dense-flowered racemes; pedicels in pairs. Perianth cylindrical; the segments at first cohering by their margins, but ultimately separating and revolute to the base. Stamens affixed above the middle of the segments; filaments very short; anthers long, linear, acute. Hypogynous glands 4, distinct. Ovary sessile, 1-celled; style long, straight, linear-clavate; ovules 4. Follicles coriaceous, 1-celled, 4-seeded. Seeds winged at the top.

A small genus of 3 species, the typical one confined to New Zealand. The remaining 2 are natives of New Caledonia, and form the subgenus *Eucarpha*, characterized by the large deciduous bracts.

1. **K. excelsa** *R. Br. in Trans. Linn. Soc.* x (1810) 194, t. 2.—A tall slender tapering tree 60–90 ft. high, with the narrow fastigiate mode of growth of a Lombardy poplar; trunk 2–4 ft. diam.; bark dark-brown or almost black; branches erect, the younger ones angled and clothed with rusty brown pubescence. Leaves of mature trees 4–6 in. long, linear-oblong or narrow obovate-oblong, obtuse, coarsely and bluntly toothed, very coriaceous, hard, rigid, almost woody, pubescent when young, quite glabrous when old; leaves of young trees not so coriaceous, longer and narrower, 4–10 in. long, linear or linear-lanceolate, often acute, more acutely serrate. Racemes lateral, sessile, 2–4 in. long; peduncles and perianth densely clothed with bright red-brown velvety tomentum. Flowers in pairs on short pedicels, densly crowded, 1–1$\frac{1}{2}$ in. long. Perianth cylindric, swollen above; segments separating to the base and coiling up into a twisted mass. Ovary tomentose; style 1–1$\frac{1}{4}$ in. long, stout, erect, clavate

BROWN-- NEW POLYNESIAN PLAN. P.II. Dianella.
Occasional papers IX, 4.1930 2.

Dianella intermedia Endlicher var Norfolkensis new var.
"Leaves 50-100 cms. in length 12-18 ± mm. in width, obscurely spinulose -serrate to smooth along themargin and keel; flowers small; tepals 5mm. long, the outer series 5-veied, greenish-white to purplish in colour, not distinctly punctate; inter tepals somewhat broader, 3-veined with a wide hyaline border, nearly white in colour; anthers 2.5 ± mm. in length, commonly longer than the filaments; seed broadly oral, sub-acute, truncate at the base, 3.5 ± mm. long."
NEW ZEALAND, KAURI GULCH, near AUCKLAND, JANUARY 16th, 1921, F.B.H. BROWN, no. 162, reference type.

"Leaves obscurely serrulate t smooth, 60 ± cm. in length, 18± mm. in width; panicle of nearly the same height as the leaves; flowers small; tepals 5 mm. long, not distinctly punctate; outer tepals 5-veined, greenish in colour; inner tepals slightly wider 3-veined, nearly white, anthers 2.5 mm., nearly twice the length of the filaments; seed broadly ovate-elliptical in outline, obtuse to subacute at the apex, truncate or obtusely rounded at the base, 4 ± mm. in length, 2.5-3 mm. in width." FIJI, Lakemba, Sept.3rd, 1924. Edwin H. Bryan, Jr. no. 534 reference type.

The area of distribution includs Norfolk Is., Fiji at moderate altitudes, and N.Z. from sea-level o about 800 metres (Cheeseman; Manual of N.Z. Flora, p.320, 1925). Ntive names in N.Z. are pepe, piopio and turutu; in Fiji, vara.

Also a reference to Cypenis tenulus var. Australiensis

above. Follicles 1½ in. long, pubescent, tapering into the persistent style, ultimately splitting into 2 boat-shaped valves.—*A. Cunn. Precur.* (1838) n. 350 ; *Raoul Choix* (1846) 42 ; *Hook. f. Fl. Nov. Zel.* i (1853) 219 ; *T. Kirk Forest Fl.* (1889) t. 35 ; *Cheesem. Man. N.Z. Fl.* (1906) 606 ; *Ill. N.Z. Fl.* ii (1914) t. 171.

North Island : Common in woods throughout. South Island : Southern shores of Cook Strait, Croixelles Harbour, *T. Kirk ;* Pelorus Sound, *Buchanan, J. Rutland !* Sea-level to 2800 ft. *Honeysuckle ; Rewarewa.* November–December.

A tall handsome tree, easily distinguished by its fastigiate mode of growth. The wood is beautifully variegated, reddish on a light-brown ground, and is much used for inlaying and cabinetwork, ornamental turnery, &c. For an account of the fertilization of the flowers, see a paper by myself in vol. ii of the Journal of the Australasian Association. Mr. A. Allison sends me a curious sport in which the leaves are dichotomously forked.

Family XXX. **SANTALACEAE.**

Trees or shrubs or herbs, often parasitic on the roots of other plants. Leaves alternate or opposite, simple and entire, sometimes reduced to minute scales or altogether wanting ; stipules absent. Flowers regular, hermaphrodite or unisexual, usually small and greenish, solitary or in axillary or terminal cymes or spikes. Perianth superior or inferior, 3–6-lobed or -partite ; lobes valvate, often hairy behind the anthers. Stamens 3–6, inserted on the perianth-lobes and opposite to them ; anthers 2-celled. Ovary inferior, rarely superior, 1-celled ; style short ; stigma capitate or 3–4-lobed ; ovules 2–3, pendulous from a central column. Fruit an indehiscent nut or drupe. Seed solitary, globose or ovoid ; albumen copious, fleshy ; embryo usually small, terete, radicle superior.

Sprague & Sumerhayes in Kew Bulletin (1927) p. 197.

MIDA (A.Cunn.) Benth.
Tendency to unisexuality. Ovary semi-inferior; shortly cupular perianth-tube; ~~strictly ♀ flowers~~. Flowers sometimes unisexual. Fruits turbinate.
M. salicifolia, A. Cunn.
"As a result of investigations in the field, Cockayne and Allan (Trans. N.Z. Inst. lvii. 57: 1927) accept M. salicifolia and M. myrtifolia as independent species, and suggest that M. eucalyptoides may be a hybrid between them. From Cunningham's descriptions of M. salicifolia and myrtifolia we are unable to draw a line between these two species in the herbarium, and await further descriptions of them by Cockayne and Allan before coming to a definite conclusion."

Family XXX. **SANTALACEAE.**

Trees or shrubs or herbs, often parasitic on the roots of other plants. Leaves alternate or opposite, simple and entire, sometimes reduced to minute scales or altogether wanting ; stipules absent. Flowers regular, hermaphrodite or unisexual, usually small and greenish, solitary or in axillary or terminal cymes or spikes. Perianth superior or inferior, 3–6-lobed or -partite ; lobes valvate, often hairy behind the anthers. Stamens 3–6, inserted on the perianth-lobes and opposite to them ; anthers 2-celled. Ovary inferior, rarely superior, 1-celled ; style short ; stigma capitate or 3–4-lobed ; ovules 2–3, pendulous from a central column. Fruit an indehiscent nut or drupe. Seed solitary, globose or ovoid ; albumen copious, fleshy ; embryo usually small, terete, radicle superior.

A family of moderate size, widely dispersed in both temperate and tropical regions. era 28 ; species not much exceeding 250. The only species of much economic value *antalum album*, which yields the well-known sandalwood. Both the New Zealand era are found in Australia, and *Exocarpus* extends also to the Pacific islands, Malay lipelago, and Madagascar.

fy. Perianth superior. Flowers in axillary cymes .. 1. Fusanus.
fless. Perianth inferior. Flowers in axillary spikes .. 2. Exocarpus.

1. **FUSANUS** R. Br.

Glabrous trees or shrubs. Leaves opposite or alternate. Flowers maphrodite or unisexual by abortion, in axillary or terminal racemes fascicles. Perianth-tube turbinate, adnate to the ovary and produced ve it into a projecting rim ; segments 4–6, each furnished with a tuft nairs at the base. Stamens 4–6, affixed to the base of the perianth-nents and shorter than them ; anthers ovate, dehiscing longitudinally. lining the projecting part of the perianth-tube. Ovary inferior ; style t, conic ; stigma small, 2–4-lobed ; ovules 2–4. Fruit a globose or inate drupe crowned at the summit by the annular scar of the perianth-nents ; exocarp more or less fleshy ; endocarp hard, often rugose. bryo linear, in the centre of the albumen.

A small genus of 5 species, all Australian except the one found in New Zealand.

1. **F. Cunninghamii** *Benth. and Hook. f. ex T. Kirk Forest Fl.* (1889) t. 75, 76.—A small slender tree 10–25 ft. high; trunk seldom more than 9 in. diam.; bark grey. Leaves alternate or more rarely opposite, extremely variable in shape, 2–5 in. long, $\frac{1}{5}$–1 in. broad, linear-lanceolate or lanceolate to ovate-lanceolate or elliptic-oblong or obovate, acute or acuminate, narrowed into short petioles, quite entire, dark-green and glossy, veined, minutely punctate. Inflorescence axillary, of few- or many-flowered racemes or cymes, rarely reduced to few-flowered fascicles. Flowers small, $\frac{1}{6}$–$\frac{1}{4}$ in. diam., brownish-green, hermaphrodite or unisexual by abortion, the females the smallest. Perianth-tube hemispherical; segments 4–6, triangular, deciduous, each with a tuft of yellowish hairs at the base. Stamens the same number as the perianth-segments; filaments short, slender. Disc 4–6-lobed. Stigma 2–4-lobed. Drupe $\frac{1}{3}$–$\frac{1}{2}$ in. long, narrow-turbinate, bright-red, crowned with the annular scar of the perianth-segments.—*Cheesem. Man. N.Z. Fl.* (1906) 624; *Ill. N.Z. Fl.* ii (1914) t. 177. Santalum Cunninghamii *Hook. f. Fl. Nov. Zel.* i (1853) 223; *Handb. N.Z. Fl.* (1864) 247. S. mida *Hook. Ic. Plant.* (1843) tt. 563, 575; *Raoul Choix* (1846) 42. Mida salicifolia, M. eucalyptoides, *and* M. myrtifolia *A. Cunn. Precur.* (1838) n. 340, 341, 342. Ann. Nat. Hist. V1, p. 376

North Island: Lowland forests from the North Cape to Cook Strait, but local to the south of Rotorua. Sea-level to 2000 ft. *Maire; New Zealand Sandalwood.* September–October.

This differs from the Australian species of the genus in the alternate leaves, axillary inflorescence, and turbinate fruit. Cunningham constituted a separate genus for it under the name of *Mida*, and divided it into 3 species based upon the greater or lesser breadth of the leaves. But as leaves of all intermediate shapes can easily be found, and sometimes occur on the same branch, it is impossible to separate his species even as varieties. The wood is hard and dense, very strong and durable, and is occasionally used for ornamental turnery, inlaying, &c.

2. **EXOCARPUS** Labill. 1798. 1:155 t. 14.

Shrubs or small trees. Leaves alternate or rarely opposite, often reduced to minute scales. Flowers minute, hermaphrodite or unisexual by abortion, in small axillary spikes or fascicles, each flower sessile or nearly so in a notch of the rhachis or axillary to a minute scale-like bract. Perianth inferior, divided to the base into 4–6 valvate segments. Stamens the same number as the perianth-segments and inserted near their base; filaments very short and broad; anthers adnate, 2-celled, longitudinally dehiscent. Disc flat, thick, sinuately 4–6-lobed. Ovary superior, fleshy, conic; stigma small, sessile, entire or obscurely lobed. Fruit a nut or drupe seated on the enlarged and often succulent and coloured pedicel. Seed erect; testa thin; albumen copious; embryo minute, cylindric.

Species 16, 9 of which are found in Australia, one of them extending to the Malay Archipelago. The remaining 7 are found in Lord Howe Island, Norfolk Island, New Zealand, the Sandwich Islands, and Madagascar.

1. **E. Bidwillii** *Hook. f. Fl. Nov. Zel.* i (1853) 223, t. 52.—A small much-branched rigid procumbent shrub 6–24 in. high; branches ascending, short, stiff, terete, deeply furrowed. Leaves reduced to minute triangular scales, alternate, persistent. Flowers minute, arranged in short and stout 4–10-flowered spikes springing from the axils of the scale-like leaves; rhachis pubescent, excavated at the insertion of each flower; bract minute.

Perianth-segments usually 5, but sometimes 4 or 6. Stamens the same number; filaments short. Nut oblong, black, about $\frac{1}{5}$ in. long, peduncle much enlarged and thickened, often red and succulent, the perianth-segments persistent under the fruit.—*Handb. N.Z. Fl.* (1864) 246; *Cheesem. Man. N.Z. Fl.* (1906) 625.

long; stigma simple; ovule solitary, erect, adnate to the walls of the ovary. Fruit a 1-seeded berry or drupe, pericarp usually viscid. Seed generally albuminous; embryo straight, axile, radicle superior.

A family comprising 21 genera and about 525 species, chiefly found in the tropical or warm regions of both hemispheres, with comparatively few species in the temperate zones. The order has no important properties or economic value, and the common mistletoe is the only species of any repute. Of the 5 New Zealand genera, *Tupeia* is endemic; the remaining two are widely distributed in both temperate and tropical climates.

* Perianth double.

Ovary more or less distinctly 2- or more celled	1. ELYTRANTHE.
Ovary distinctly 1-celled. Anthers basifixed	2. LORANTHUS.
Ovary distinctly 1-celled. Anthers versatile	3. PHRYGILANTHUS.

** Perianth single.

Leafy. Flowers in axillary or terminal panicles	4. TUPEIA.
Leafless. Flowers at the nodes of the jointed stems or branches	5. KORTHALSELLA.

An important series of memoirs on the structure and classification of this family, by the French botanist Van Tieghem, was printed in the Bulletin of the Botanical Society of France for the years 1894–96 (vols. xli–xliii). One of these memoirs, entitled "Sur les Loranthoidées de la Nouvelle-Zelande," deals specially with the New Zealand species, and contains many original and valuable observations. Van Tieghem's researches have to a large extent supplied the basis of a new classification of the family proposed by Engler in "Die Pflanzenfamilien" (Nachtrage, i, 124), although most of his genera are reduced to the position of subgenera or sections. The following arrangement of the New Zealand species is based largely on Engler's views.

1. ELYTRANTHE Blume.

Parasitic shrubs. Leaves opposite, rarely alternate, usually coriaceous. Flowers hermaphrodite, often brilliantly coloured, red, orange, or yellow, rarely green; sessile in the axils of the leaves, or more generally arranged in short spikes or stalked clusters. Perianth double; outer (calyx) adnate to the ovary, limb obscurely sinuate or truncate; inner (corolla) tubular

1. **F. Cunninghamii** *Benth. and Hook. f. ex T. Kirk Forest Fl.* (1889) t. 75, 76.—A small slender tree 10–25 ft. high; trunk seldom more than 9 in. diam.; bark grey. Leaves alternate or more rarely opposite, extremely variable in shape, 2–5 in. long, $\frac{1}{5}$–1 in. broad, linear-lanceolate or lanceolate [illegible] or obovate, acute or acuminate

(Fusanus cunninghamii, Benth & Hk.)

= 1. Mida salicifolia, (A. Cunn) Ckn. & Allan.

2. Mida myrtifolia (A. Cunn) Ckn. & Allan.

("The species hybridize where they meet and produce 'intermediates'".)

see T.N.Z.I. vol. 57, p. 57. (Ckn. & Allan.)

to the south of Rotorua. Sea-level to 2000 ft. *Maire; New Zealand Sandalwood.* September–October.

This differs from the Australian species of the genus in the alternate leaves, axillary inflorescence, and turbinate fruit. Cunningham constituted a separate genus for it under the name of *Mida*, and divided it into 3 species based upon the greater or lesser breadth of the leaves. But as leaves of all intermediate shapes can easily be found, and sometimes occur on the same branch, it is impossible to separate his species even as varieties. The wood is hard and dense, very strong and durable, and is occasionally used for ornamental turnery, inlaying, &c.

2. **EXOCARPUS** Labill. 1798. 1:155 t. 14.

Shrubs or small trees. Leaves alternate or rarely opposite, often reduced to minute scales. Flowers minute, hermaphrodite or unisexual by abortion, in small axillary spikes or fascicles, each flower sessile or nearly so in a notch of the rhachis or axillary to a minute scale-like bract. Perianth inferior, divided to the base into 4–6 valvate segments. Stamens the same number as the perianth-segments and inserted near their base; filaments very short and broad; anthers adnate, 2-celled, longitudinally dehiscent. Disc flat, thick, sinuately 4–6-lobed. Ovary superior, fleshy, conic; stigma small, sessile, entire or obscurely lobed. Fruit a nut or drupe seated on the enlarged and often succulent and coloured pedicel. Seed erect; testa thin; albumen copious; embryo minute, cylindric.

Species 16, 9 of which are found in Australia, one of them extending to the Malay Archipelago. The remaining 7 are found in Lord Howe Island, Norfolk Island, New Zealand, the Sandwich Islands, and Madagascar.

1. **E. Bidwillii** *Hook. f. Fl. Nov. Zel.* i (1853) 223, t. 52.—A small much-branched rigid procumbent shrub 6–24 in. high; branches ascending, short, stiff, terete, deeply furrowed. Leaves reduced to minute triangular scales, alternate, persistent. Flowers minute, arranged in short and stout 4–10-flowered spikes springing from the axils of the scale-like leaves; rhachis pubescent, excavated at the insertion of each flower; bract minute.

Perianth-segments usually 5, but sometimes 4 or 6. Stamens the same number; filaments short. Nut oblong, black, about $\frac{1}{5}$ in. long, peduncle much enlarged and thickened, often red and succulent, the perianth-segments persistent under the fruit.—*Handb. N.Z. Fl.* (1864) 246; *Cheesem. Man. N.Z. Fl.* (1906) 625.

SOUTH ISLAND: Not uncommon in the mountains of Nelson, Marlborough, Canterbury, and northern Otago. 1000–4000 ft. December–February.

See Pflanzenfam. 166. 1935:98

Family XXXI. LORANTHACEAE.

Parasitic shrubs. Leaves opposite or alternate, simple and entire, coriaceous, sometimes reduced to scales or wanting; stipules absent. Flowers regular, hermaphrodite or unisexual, axillary or terminal, solitary or in racemes or spikes or fascicles, usually with a bract on each pedicel and 2 bracteoles below each flower. Perianth double, outer adnate to the ovary, limb short or barely evident, truncate or 4–6-toothed; inner 3–6-lobed, lobes free or united into a tube, valvate. Stamens as many as the divisions of the perianth, usually inserted on them; filaments short or long; anthers introrse, 2-celled. Ovary inferior, 1-celled; style short or long; stigma simple; ovule solitary, erect, adnate to the walls of the ovary. Fruit a 1-seeded berry or drupe, pericarp usually viscid. Seed generally albuminous; embryo straight, axile, radicle superior.

A family comprising 21 genera and about 525 species, chiefly found in the tropical or warm regions of both hemispheres, with comparatively few species in the temperate zones. The order has no important properties or economic value, and the common mistletoe is the only species of any repute. Of the 5 New Zealand genera, *Tupeia* is endemic; the remaining two are widely distributed in both temperate and tropical climates.

* Perianth double.

Ovary more or less distinctly 2- or more celled	1. ELYTRANTHE.
Ovary distinctly 1-celled. Anthers basifixed	2. LORANTHUS.
Ovary distinctly 1-celled. Anthers versatile	3. PHRYGILANTHUS.

** Perianth single.

Leafy. Flowers in axillary or terminal panicles	4. TUPEIA.
Leafless. Flowers at the nodes of the jointed stems or branches	5. KORTHALSELLA.

An important series of memoirs on the structure and classification of this family, by the French botanist Van Tieghem, was printed in the Bulletin of the Botanical Society of France for the years 1894–96 (vols. xli–xliii). One of these memoirs, entitled "Sur les Loranthoidées de la Nouvelle-Zelande," deals specially with the New Zealand species, and contains many original and valuable observations. Van Tieghem's researches have to a large extent supplied the basis of a new classification of the family proposed by Engler in "Die Pflanzenfamilien" (Nachtrage, i, 124), although most of his genera are reduced to the position of subgenera or sections. The following arrangement of the New Zealand species is based largely on Engler's views.

1. ELYTRANTHE Blume. 1930

Parasitic shrubs. Leaves opposite, rarely alternate, usually coriaceous. Flowers hermaphrodite, often brilliantly coloured, red, orange, or yellow, rarely green; sessile in the axils of the leaves, or more generally arranged in short spikes or stalked clusters. Perianth double; outer (calyx) adnate to the ovary, limb obscurely sinuate or truncate; inner (corolla) tubular

or funnel-shaped, usually ultimately splitting into 5–6 segments with recurved tips. Stamens 5–6, inserted on the perianth-segments; anthers basifixed, not versatile. Style filiform; stigma capitate or clavate. Ovary more or less distinctly 2- or more-celled. Fruit a globose or broadly oblong berry.

A genus of from 70 to 80 species, extending from India to Malaya, eastern Polynesia, Australia, and New Zealand. All the New Zealand species are endemic.

* Petals free to the base.

Flowers 1½–2 in. long, in 3–9-flowered racemes	1. *E. Colensoi.*
Flowers 1 in. long, axillary, solitary or 2–4 together ..	2. *E. tetrapetala.*

** Petals united to the middle or nearly so (sometimes dorsally split to the base in *L. Adamsii*).

Flowers 1½–2 in. long, 2 to 4 at the top of a short axillary peduncle	3. *E. Adamsii.*
Flowers ½–¾ in. long, in 10–15-flowered racemes	4. *E. flavida.*

Peraxilla Van Tiegh.

1. **E. Colensoi** *Engl. Pflanzenf. Nachtr.* i (1897) 126.—A large much-branched perfectly glabrous bush; branchlets terete. Leaves opposite, 1½–3 in. long, broadly oblong or obovate or almost orbicular, obtuse, narrowed into a stout petiole ½–¾ in. long, very thick and coriaceous, veinless or the veins very obscure. Peduncles stout, axillary, ½–1 in. long, 3–9-flowered. Flowers sessile, opposite, large, scarlet, 1½–2 in. long; a small deciduous leaf-like bract at the base of each flower; bracteoles wanting. Calyx-limb prominent, cupular, truncate or obscurely sinuate. Corolla terete or nearly so in bud, swollen at the base and towards the tip, splitting into 4 linear petals free to the base. Anthers very narrow-linear, basifixed. Style straight, equalling the corolla.—Loranthus Colensoi *Hook. f. in Hook. Ic. Plant.* (1844) t. 633; *Handb. N.Z. Fl.* (1864) 107; *Cheesem. Man. N.Z. Fl.* (1906) 619. Peraxilla Colensoi *Van Tiegh. in Bull. Soc. Bot. Fr.* xli (1894) 500.

North Island: Lake Waikaremoana, parasitic on *Metrosideros tomentosa*, *Colenso!* Mount Hikurangi and other places in the East Cape district, *Adams* and *Petrie*, *Bishop Williams!* various localities in Wellington Province, *Buchanan! B. C. Aston!* South Island: Not uncommon in wooded districts throughout. Sea-level to 2000 ft. December–January.

A very handsome species. It is usually parasitic on *Nothofagus*, but has also been noticed on *Pittosporum* and *Metrosideros*.

Mr. Mayo informs me that this is occasionally seen on introduced trees. At Motueka (Nelson) he has observed it growing on Pears, Plums, and on *Robinia pseudacacia*.

Peraxilla (Hook.f.) Van Tiegh.

2. **E. tetrapetala** *Engl. Pflanzenf. Nachtr.* i (1897) 126.—A bushy shrub 3–6 ft. high; stems usually numerous from the base, often adhering to the host for a considerable distance; branches spreading, terete, greyish; branchlets compressed, glabrous or minutely pubescent. Leaves opposite and decussate, ½–1¼ in. long, elliptic-oblong or ovate-oblong, rounded at the tip, narrowed into a short petiole at the base, very thick and coriaceous, pale yellowish-green when fresh, reddish when dry, midrib and veins obscure. Flowers bright-red, either solitary or 2–4 together in the axils of the leaves, erect; peduncles short, stout. Calyx-limb cupular, obscurely 4-toothed. Corolla about 1 in. long, swollen and 4-angled at the base, terete above, ultimately splitting to the base into 4 linear petals, which are erect below, but reflexed at the tip. Anthers narrow-linear,

basifixed. Style equalling the corolla; stigma capitate.—Loranthus tetrapetalus *Forst. f. Prodr.* (1786) n. 156; *A. Rich. Fl. Nouv. Zel.* (1832) 268; *A. Cunn. Precur.* (1838) n. 486; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 99; *Handb. N.Z. Fl.* (1864) 107. Loranthus Fieldii *Buch. in Trans. N.Z. Inst.* xvi (1884) 397; *Cheesem. Man. N.Z. Fl.* (1906) 619. L. decussatus *T. Kirk in Trans. N.Z. Inst.* iii (1871) 162. L. punctatus *Col. in Trans. N.Z. Inst.* xv (1883) 323. Peraxilla tetrapetala *Van Tiegh. Bull. Soc. Bot. Fr.* xli (1894) 500.

North and South Islands: Not uncommon from the Little Barrier Island and Cape Colville to the south-west of Otago. 500–4000 ft. November–January.

In the southern portion of the Dominion this is usually parasitic on *Nothofagus*, in the north on *Quintinia*. Through a curious misconception, Mr. Kirk applied the name of *tetrapetalus* to the plant now known as *L. Adamsii*, and described the true *tetrapetalus* as a distinct species under the name of *L. decussatus*.

Colenso's *Loranthus punctatus* (*Peraxilla punctata* Van Tiegh., *Elytranthe punctata* Engl.) is doubtless identical with this species, judging from an imperfect specimen in his herbarium. Van Tieghem's *Peraxilla uniflora* and *P. Haastii*, both of which are accepted and referred to *Elytranthe* by Engler, are said to be closely allied; but as no descriptions or diagnostic characters are given I cannot express any opinion as to their validity. Van Tieghem also retains Kirk's *Loranthus decussatus* as a distinct species; placing it, under the name of *Peraxilla decussata*, in the immediate neighbourhood of *E. Colensoi*, with which he states it agrees in having the flowers in axillary racemes. No doubt he has been influenced by Kirk's original description, in which the flowers are described as being arranged in "2–4-flowered racemes." But the type specimens in Kirk's herbarium all have the flowers solitary in the axils of the leaves, and this is also the case with specimens collected by myself in the locality where it was first obtained by Kirk. I can entertain no doubt of its identity with *E. tetrapetalus*, and consider that the mistake in Kirk's diagnosis was probably due to some accidental mixture of specimens. As mentioned in the body of this work, the name of *L. tetrapetalus* is applied in Kirk's herbarium to the following species.

Trilepidea (Elytr.) Van Tiegh.

3. **E. Adamsii** *Engl. Pflanzenf. Nachtr.* i (1897) 126.—A perfectly glabrous bush 2–4 ft. high; branchlets terete. Leaves opposite, $1\frac{1}{2}$–$2\frac{1}{4}$ in. long, broadly oblong or oblong-obovate, obtuse, narrowed into a short stout petiole or almost sessile, very thick and coriaceous, veins hardly visible, margins slightly recurved. Peduncles very short, axillary, each bearing 2–4 sessile flowers; a small concave bract and 2 bracteoles at the base of each flower. Flowers rather large, $1\frac{1}{2}$–2 in. long, reddish, more or less tinged with yellowish-green. Calyx-limb short, with 4 minute triangular teeth. Corolla narrow at the base, swollen in the middle, and then contracted just below the limb; lobes 4, separating about $\frac{1}{4}$-way down, reflexed, but the corolla often splits dorsally to the base, the lobes then all turning one way. Anthers narrow-linear, basifixed, tips acute. Style equalling the corolla; stigma capitate. Fruit oblong, bright-red, $\frac{1}{3}$ in. long.—Loranthus Adamsii *Cheesem. in Trans. N.Z. Inst.* xiii (1881) 296; *Man. N.Z. Fl.* (1906) 620; *Ill. N.Z. Fl.* ii (1914) t. 176. Trilepidea Adamsii *Van. Tiegh. in Bull. Soc. Bot. Fr.* xli (1894) 489.

North Island: Auckland—Tryphena Harbour (Great Barrier Island), near the base of Moehau Mountain, Cape Colville, *W. Townson! A. J. Osborne!* Thames goldfields, *Adams! T. F. C., W. Townson!* Hunua, *T. Kirk!*

The foliage of this closely resembles that of *E. Colensoi*, but the flowers are very different. Parasitic on *Coprosma*, *Myrsine*, and *Melicope*. Van Tieghem mentions a *Trilepidea Ralphii* (Bull. Soc. Bot. Fr. xlii (1895) 28) as a closely allied species, but he gives no distinctive characters.

M.S. Hull

4. **E. flavida** *Engl. Pflanzenf. Nachtr.* i (1897) 126.—A sparingly branched glabrous shrub 1–3 ft. high; branches spreading. Leaves opposite, 1–2½ in. long, linear-oblong, usually rounded at the tip, rarely apiculate, narrowed at the base into a short petiole, flat, very coriaceous, veins inconspicuous, or 3–5 diverging from the base; margins thickened and very minutely crenulate when dry, often red when fresh. Racemes axillary, 10–16-flowered, spreading or drooping, ¾–2 in. long; peduncle slender, tetragonous; pedicels opposite and decussate, about ⅙ in. long; bracts obsolete. Flowers ½–¾ in. long, orange-yellow. Calyx-limb minute, cupular, truncate. Corolla slender, swollen above the base; petals united almost to the middle, upper part sharply reflexed, linear-spathulate. Anthers small, linear-oblong. Style rather longer than the corolla; stigma large, capitate.—Loranthus flavidus *Hook. f. Fl. Nov. Zel.* i (1853) 100, t. 27; *Handb. N.Z. Fl.* (1864) 107; *Cheesem. Man. N.Z. Fl.* (1906) 620. L. polychroa *Col. in Trans. N.Z. Inst.* xvii (1885) 241. Alepis flavida *Van Tiegh. Bull. Bot. Soc. Fr.* xli (1894) 489.

North and South Islands: Not uncommon in *Nothofagus* forests from the East Cape, Ruapehu, and Mount Egmont southwards. Sea-level to 3500 ft. December–February.

Van Tieghem accepts Colenso's *Loranthus polychroa*, giving it the name of *Alepis polychroa*. Probably he did not see any specimens, for the examination of one given to me by Mr. Colenso leaves no doubt in my mind that it is absolutely identical with *E. flavida*.

1. **LORANTHUS** Linn.

Parasitic shrubs. Leaves opposite or rarely alternate, entire, coriaceous. Flowers hermaphrodite, often highly coloured, yellow or orange or red, rarely white or greenish, in axillary racemes or cymes, rarely solitary. Perianth double; outer (calyx) adnate to the ovary; limb short, truncate or 4–6-toothed; inner (corolla) tubular, of 4–6 free or more or less connate petals, their tips ultimately spreading or reflexed. Stamens as many as the petals and inserted on them; filaments distinct; anthers adnate. Ovary inferior, 1-celled; style filiform; stigma terminal. Fruit a berry.

A large genus of about 350 species, abundant in the tropics, but rare in temperate regions. The single New Zealand species is endemic.

1. **L. micranthus** *Hook. f. Fl. Nov. Zel.* i (1853) 100.—A perfectly glabrous bushy shrub 2–5 ft. high; branches terete, the younger ones flattened and 2-edged. Leaves opposite, 1½–3 in. long, oblong or elliptic-oblong or oblong-obovate, rounded at the tip, narrowed into a stout petiole about ⅓ in. long, thick and coriaceous, veins very obscure. Panicles small, ½–¾ in. long, axillary, trichotomously branched, many-flowered; branches slender, divaricating. Flowers minute, greenish, ⅛ in. long. Calyx-tube cylindrical; limb very minute, truncate. Corolla of 4 linear-oblong spreading petals, free to the base. Anthers small, oblong, basifixed. Style stout, short, suddenly twisted up and down at the middle; stigma lateral, capitate. Berry bright-yellow, oblong, viscid, ⅓ in. long.—*Handb. N.Z. Fl.* (1864) 107; *Cheesem. Man. N.Z. Fl.* (1906) 618, 1149. Ileostylus micranthus *Van Tiegh. in Bull. Soc. Bot. Fr.* xli (1894) 489. I. Kirkii *Van Tiegh. l.c.* xliii (1895) 25. V. antarcticum *A. Cunn. Precur.* (1838) n. 483 (*not of Forst.*).

North and South Islands, Stewart Island: Abundant in lowland districts throughout. Sea-level to 2000 ft. October–November.

Easily distinguished by its small green flowers. Parasitic on *Coprosma, Melicope, Leptospermum,* &c. At the native settlement of Waihi, at the south end of Lake Taupo, it grows in great abundance on Pear and Plum trees. Van Tieghem's *Ileostylus Kirkii* is based upon specimens collected near Auckland by Kirk, and is said to differ from the type in the shape and structure of the leaves. But no second species exists in Mr. Kirk's herbarium, and the typical form is the only one I have seen near Auckland.

3. **PHRYGILANTHUS** Eichl.

Parasitic shrubs. Leaves opposite, seldom alternate, coriaceous. Flowers conspicuous, red, yellow, or white, usually arranged in few- or many-flowered trichotomous panicles. Perianth double; outer (calyx) adnate to the ovary, limb short, obscurely 4–6-toothed or almost truncate; inner (corolla) of 4–6 free or slightly cohering petals. Stamens 5–6, long and filiform; anthers versatile; pollen 3-lobed. Style long, filiform, ovary 1-celled. Fruit globose or oblong.

A widely diffused tropical genus, containing from 20 to 30 species. The two found in New Zealand are both endemic.

Flowers in axillary trichotomous panicles .. .. .. 1. *P. tenuiflorus.*
Flowers in terminal trichotomous panicles .. .. .. 2. *P. Raoulii.*

1. **P. tenuiflorus** (Hook. f.) *Engl. Pflanzenf. Nachtr.* i (1897) 134. — A small glabrous shrub; branches slender, terete. Leaves opposite, 1–1½ in. long, obovate or obovate-oblong, obtuse, narrowed into short slender petioles, veins few, slender. Flowers about 1 in. long, in axillary trichotomous puberulous panicles; peduncles and pedicels slender, divaricating, about ¼ in. long. Corolla slender, terete, curved; petals very narrow, united ⅔-way up, but perhaps ultimately separating. Anthers oblong, versatile. Style slender; stigma simple.—Loranthus tenuiflorus *Hook. f. Fl. Nov. Zel.* i (1853) 100; *Handb. N.Z. Fl.* (1864) 107; *Cheesem. Man. N.Z. Fl.* (1906) 620. Hookerella tenuiflora *Van. Tiegh. in Bull. Soc. Bot. Fr.* xiii (1895) 25.

North Island: Locality unknown.

Founded upon a single specimen in the Kew Herbarium, the exact locality of which is not known. It is evidently a most distinct species, differing from all others found in New Zealand (except the following) in the many-flowered trichotomous panicles and versatile anthers. The latter are not fully described by Hooker, but in the "Genera Plantarum" the species is referred to *Phrygilanthus,* in which they are versatile.

2. **P. Raoulii** Van Tiegh. *Engl. Pflanzenf. Nachtr.* i (1897) 134.—I have seen no specimens of this, which is quite unknown to New Zealand botanists. According to Van Tieghem, it differs radically from *P. tenuiflorus* in the inflorescence being terminal and not axillary, and in the flowers being pentamerous.—Mullerina Raoulii *Van Tiegh. in Bull. Soc. Bot. Fr.* xlii (1895) 25.

North Island: Bay of Islands, *Raoul* (on *Metrosideros*); Whangaroa, *A. Cunningham* (on *Metrosideros* and *Vitex*).

According to Van Tieghem, this species was confused by both Cunningham and Raoul with Forster's *Loranthus tetrapetalus,* the *Elytranthe tetrapetala* of this work. In his "Precursor," Cunningham certainly speaks of *L. tetrapetalus* as having been gathered by himself and his brother at the Bay of Islands and Whangaroa, districts altogether outside the range of Forster's *L. tetrapetalus.* Raoul includes *L. tetrapetalus* in the list of plants collected by himself, but does not give any locality. It is much to be desired that some resident at the Bay of Islands or Whangaroa would investigate the matter.

4. **TUPEIA** Cham. et Schl.

A parasitic shrub; branches terete, jointed. Leaves opposite or alternate, flat, broad or narrow. Flowers dioecious, in small axillary and terminal panicles. Perianth-tube of the male flowers very small, of the female flowers adnate to the ovary; limb 4-partite, rarely 5-partite. Stamens in the male flowers affixed to the base of the segments; filaments long, filiform; anthers ovate-oblong. Ovary in the female flowers inferior, ovoid; style short and thick; stigma obtuse. Fruit a subglobose 1-seeded berry; mesocarp succulent and viscid. Seed globose; albumen copious, fleshy; embryo almost terete.

The genus is limited to a single species, endemic in New Zealand.

1. **T. antarctica** *Cham. and Schl. in Linnaea*, iii (1828) 203.—A small branching shrub 2–3 ft. high; bark pale; branchlets finely pubescent. Leaves very variable in size and shape, $\frac{1}{2}$–$2\frac{1}{2}$ in. long, from broad ovate-rhomboid to elliptic- or oblong-lanceolate, acute or obtuse, narrowed into short petioles, pale-green, rather thin; veins faint but evident, anastomosing. Panicles shorter than the leaves, 6–12-flowered; peduncles and pedicles slender, pubescent. Flowers small, $\frac{1}{6}$ in. diam., greenish-yellow, often very abundantly produced. Segments of the male perianth linear-oblong or oblong-spathulate, of the female narrower and more acute. Stigma large, globular, obscurely lobed. Berry about $\frac{1}{4}$ in. diam., white or pink spotted with darker pink; pulp extremely viscid.—*Hook. f. Fl. Nov. Zel.* i (1853) 101, t. 26; *Handb. N.Z. Fl.* (1864) 108; *Cheesem. Man. N.Z. Fl.* (1906) 621. T. Cunninghamii *Miq. in Linnaea*, xviii (1844) 85. T. pubigera *Miq. l.c.* 86. T. undulata *Col. in Trans. N.Z. Inst.* xvi (1884) 329. Viscum antarcticum *Forst. f. Prodr.* (1786) n. 370; *A. Rich. Fl. Nouv. Zel.* (1832) 269; *Raoul Choix* (1846) 42. V. pubigerum *A. Cunn. Precur.* (1836) 484.

North and South Islands: Not uncommon in wooded districts throughout. Sea-level to 3000 ft. *Pirita.* October–December.

Van Tieghem draws attention to the fact that this species is not simply dioecious, as described by Hooker, but consists of three sorts of individuals—hermaphrodites, males, and females. This peculiarity was first pointed out by A. Richard, from Foster's manuscripts (Flore Nouv.-Zel. 269).

Tupeia is occasionally doubly parasitic. Many years ago Kirk recorded an instance where it was parasitic on *Elytranthe*, growing on *Nothofagus*. Quite lately Mr. W. A. Thomson has brought under my notice an instance where it was growing on *Loranthus micranthus*, in its turn parasitic on the common hawthorn!

5. **KORTHALSELLA** Van Tiegh.

Parasitic shrubs, often of small size; branches opposite, divaricate and dichotomous, flattened or terete, jointed; leaves wanting or reduced to minute scales. Flowers monoecious, very small, arranged in whorls or spikes at the top of the joints of the stem or branches. Perianth-tube of the male flowers very short and solid; of the females adnate to the ovary, limb 3–4-partite. Stamens 3–4; anthers 2-celled. Ovary inferior; stigma large, sessile. Fruit a 1-seeded berry, usually crowned by the remains of the perianth.

From 15 to 20 species are known, ranging from India and Malaya southwards and eastwards to New Zealand and the Sandwich Islands. *Korthalsella amentacea* Van Tieghem, a New Caledonian species, is erroneously stated in the "Pflanzenfamilien" to be a native of New Zealand.

Joints terete, $\frac{1}{10}$–$\frac{1}{3}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad. Flowers sessile, in whorls between the joints .. .. 1. *K. salicornioides.*
Joints flat, broadly obovate, $\frac{1}{5}$–$\frac{1}{2}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad. Flowers spicate, the spikes in lateral pairs and 1–3 terminal .. 2. *K. Lindsayi.*
Joints flat, linear-spathulate, $\frac{1}{4}$–$\frac{1}{2}$ in. long, $\frac{1}{20}$–$\frac{1}{8}$ in. broad. Flowers spicate, the spikes solitary .. .. .. 3. *K. clavata.*

1. **K. salicornioides** *Van. Tiegh. in Bull. Soc. Bot. Fr.* xliii (1896) 165.—A small tufted perfectly glabrous much-branched leafless species 2–4 in. high; branches opposite, rather succulent, terete, jointed; joints $\frac{1}{10}$–$\frac{1}{3}$ in. long, $\frac{1}{25}$ in. broad, terete or obscurely flattened, expanded at the tip. Flowers very minute, dioecious, 4–8 together at the nodes, forming a ring round the branch, partly concealed by the expanded tip of the joints. Male flowers much the smallest; perianth-segments 3, triangular, each bearing a sessile anther on its inner face. Female flowers more numerous; ovary ovoid, crowned by 3 very minute perianth-lobes. Fruit $\frac{1}{20}$ in. long, ellipsoid, tipped by the persistent perianth-segments.—Viscum salicornioides *A. Cunn. Precur.* (1838) n. 485; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 101; *Handb. N.Z. Fl.* (1864) 108; *Cheesem. Man. N.Z. Fl.* (1906) 623.

North and South Islands: From Mangonui and Kaitaia southwards to Dunedin, but often local. Sea-level to 1500 ft.

Usually parasitic on *Leptospermum*, but also seen on *Gaultheria* and *Dracophyllum*. Although it stretches through almost the whole length of the Dominion, it is exceedingly local and rarely occurs in any great quantity. I have given a list of the chief habitats known to me in Trans. N.Z. Inst. xliii (1910) 182.

2. **K. Lindsayi** *Engl. Pflanzenf. Nachtr.* i (1897) 138.—A small succulent perfectly glabrous sparingly branched leafless little plant 2–6 in. high; branches opposite, divaricate, jointed; joints much flattened, $\frac{1}{5}$–$\frac{1}{2}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad, broadly obovate to obovate-spathulate, coriaceous,

Korthalsella clavata =
K. lindsayi, var. clavata (Kirk) Danser
see Bulletin Jard. Bot. Buitenzorg, Série III
Vol. XIV. June 1937. page 130.

naki—Mangamahu, *H. Bolton!* Wellington—Lake Wairarapa and Wainuiomata, *B. C. Aston!* South Island: Marlborough—Queen Charlotte Sound, *J. H. Macmahon!* Canterbury—Banks Peninsula, *J. B. Armstrong!* Broken River, *J. D. Enys! T. F. C.* Otago—Vicinity of Dunedin, *Lindsay, Buchanan! Petrie!* Winton, *T. Kirk:* Lake Wanaka, *Cockayne.*

Parasitic on *Sophora, Melicope, Myrtus, Metrosideros, Coprosma, Myrsine,* &c. I am indebted to Mr. Bolton for specimens of *Melicope simplex* showing both this species and *K. salicornioides* parasitic on the same branch.

4. **TUPEIA** Cham. et Schl. 1828.

A parasitic shrub; branches terete, jointed. Leaves opposite or alternate, flat, broad or narrow. Flowers dioecious, in small axillary and terminal panicles. Perianth-tube of the male flowers very small, of the female flowers adnate to the ovary; limb 4-partite, rarely 5-partite. Stamens in the male flowers affixed to the base of the segments; filaments long, filiform; anthers ovate-oblong. Ovary in the female flowers inferior, ovoid; style short and thick; stigma obtuse. Fruit a subglobose 1-seeded berry; mesocarp succulent and viscid. Seed globose; albumen copious, fleshy; embryo almost terete.

The genus is limited to a single species, endemic in New Zealand.

1. **T. antarctica** *Cham. and Schl. in Linnaea*, iii (1828) 203.—A small branching shrub 2–3 ft. high; bark pale; branchlets finely pubescent. Leaves very variable in size and shape, $\frac{1}{2}$–$2\frac{1}{2}$ in. long, from broad ovate-rhomboid to elliptic- or oblong-lanceolate, acute or obtuse, narrowed into short petioles, pale-green, rather thin; veins faint but evident, anastomosing. Panicles shorter than the leaves, 6–12-flowered; peduncles and pedicles slender, pubescent. Flowers small, $\frac{1}{6}$ in. diam., greenish-yellow, often very abundantly produced. Segments of the male perianth linear-oblong or oblong-spathulate, of the female narrower and more acute. Stigma large, globular, obscurely lobed. Berry about $\frac{1}{4}$ in. diam., white or pink spotted with darker pink; pulp extremely viscid.—*Hook. f. Fl. Nov. Zel.* i (1853) 101, t. 26; *Handb. N.Z. Fl.* (1864) 108; *Cheesem. Man. N.Z. Fl.* (1906) 621. T. Cunninghamii *Miq. in Linnaea*, xviii (1844) 85. T. pubigera *Miq. l.c.* 86. T. undulata *Col. in Trans. N.Z. Inst.* xvi (1884) 329. Viscum antarcticum *Forst. f. Prodr.* (1786) n. 370; *A. Rich. Fl. Nouv. Zel.* (1832) 269; *Raoul Choix* (1846) 42. V. pubigerum *A. Cunn. Precur.* (1836) 484.

North and South Islands: Not uncommon in wooded districts throughout. Sea-level to 3000 ft. *Pirita.* October–December.

See J. Adams' key for double perianths

as d
male
manu

when
Thon
micr

Parasitic shrubs, often of small size; branches opposite, divaricate and dichotomous, flattened or terete, jointed; leaves wanting or reduced to minute scales. Flowers monoecious, very small, arranged in whorls or spikes at the top of the joints of the stem or branches. Perianth-tube of the male flowers very short and solid; of the females adnate to the ovary, limb 3–4-partite. Stamens 3–4; anthers 2-celled. Ovary inferior; stigma large, sessile. Fruit a 1-seeded berry, usually crowned by the remains of the perianth.

From 15 to 20 species are known, ranging from India and Malaya southwards and eastwards to New Zealand and the Sandwich Islands. *Korthalsella amentacea* Van Tieghem, a New Caledonian species, is erroneously stated in the "Pflanzenfamilien" to be a native of New Zealand.

Joints terete, $\frac{1}{10}$–$\frac{1}{3}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad. Flowers sessile, in whorls between the joints	1. *K. salicornioides.*
Joints flat, broadly obovate, $\frac{1}{5}$–$\frac{1}{2}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad. Flowers spicate, the spikes in lateral pairs and 1–3 terminal ..	2. *K. Lindsayi.*
Joints flat, linear-spathulate, $\frac{1}{4}$–$\frac{1}{2}$ in. long, $\frac{1}{20}$–$\frac{1}{8}$ in. broad. Flowers spicate, the spikes solitary	3. *K. clavata.*

1. **K. salicornioides** *Van. Tiegh. in Bull. Soc. Bot. Fr.* xliii (1896) 165.—A small tufted perfectly glabrous much-branched leafless species 2–4 in. high; branches opposite, rather succulent, terete, jointed; joints $\frac{1}{10}$–$\frac{1}{3}$ in. long, $\frac{1}{25}$ in. broad, terete or obscurely flattened, expanded at the tip. Flowers very minute, dioecious, 4–8 together at the nodes, forming a ring round the branch, partly concealed by the expanded tip of the joints. Male flowers much the smallest; perianth-segments 3, triangular, each bearing a sessile anther on its inner face. Female flowers more numerous; ovary ovoid, crowned by 3 very minute perianth-lobes. Fruit $\frac{1}{20}$ in. long, ellipsoid, tipped by the persistent perianth-segments.—Viscum salicornioides *A. Cunn. Precur.* (1838) n. 485; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 101; *Handb. N.Z. Fl.* (1864) 108; *Cheesem. Man. N.Z. Fl.* (1906) 623.

North and South Islands: From Mangonui and Kaitaia southwards to Dunedin, but often local. Sea-level to 1500 ft.

Usually parasitic on *Leptospermum*, but also seen on *Gaultheria* and *Dracophyllum*. Although it stretches through almost the whole length of the Dominion, it is exceedingly local and rarely occurs in any great quantity. I have given a list of the chief habitats known to me in Trans. N.Z. Inst. xliii (1910) 182.

2. **K. Lindsayi** *Engl. Pflanzenf. Nachtr.* i (1897) 138.—A small succulent perfectly glabrous sparingly branched leafless little plant 2–6 in. high; branches opposite, divaricate, jointed; joints much flattened, $\frac{1}{5}$–$\frac{1}{2}$ in. long, $\frac{1}{8}$–$\frac{1}{3}$ in. broad, broadly obovate to obovate-spathulate, coriaceous, dark-green, often punctate. Spikes usually 2 (rarely 4) to each node and 1 to 3 at the top of the terminal joint, about $\frac{1}{4}$ in. long, jointed, the tip of each successive joint expanded and enclosing a whorl of 6–10 closely packed flowers. Flowers very minute, dioecious; the males pyriform, of 3 fleshy perianth-segments, each bearing a sessile anther on its inner face; the females of an ovoid ovary crowned by 3–4 perianth-lobes. Fruit obovoid, $\frac{1}{15}$ in. long, tipped by the persistent perianth-lobes.—Viscum Lindsayi *D. Oliver ex Hook. f. Handb. N.Z. Fl.* (1864) 108; *Lindsay Contr. N.Z. Bot.* (1868) 52, t. 2; *Cheesem. Man. N.Z. Fl.* (1906) 622. Heterixia Lindsayi *Van Tiegh. in Bull. Soc. Bot. Fr.* xliii (1896) 138.

North Island: Hawke's Bay—Norsewood, *Colenso!* Patangata, *Tryon!* Taranaki—Mangamahu, *H. Bolton!* Wellington—Lake Wairarapa and Wainuiomata, *B. C. Aston!* South Island: Marlborough—Queen Charlotte Sound, *J. H. Macmahon!* Canterbury—Banks Peninsula, *J. B. Armstrong!* Broken River, *J. D. Enys! T. F. C.* Otago—Vicinity of Dunedin, *Lindsay, Buchanan! Petrie!* Winton, *T. Kirk;* Lake Wanaka, *Cockayne.*

Parasitic on *Sophora, Melicope, Myrtus, Metrosideros, Coprosma, Myrsine,* &c. I am indebted to Mr. Bolton for specimens of *Melicope simplex* showing both this species and *K. salicornioides* parasitic on the same branch.

3. **K. clavata** *Cheesem. Man. N.Z. Fl.* (1906) 1151.—Very closely allied so *K. Lindsayi*, and perhaps only a variety, but a smaller plant, seldom more than 2 in. high, with the joints of the stem much narrower, linear-spathulate, ¼–½ in. long, $\frac{1}{20}$–⅛ in. broad. Spikes apparently always solitary, either terminal or from the nodes. Male flowers not seen, but female flowers and fruit quite like those of *K. Lindsayi*.—Viscum clavatum *T. Kirk in Trans. N.Z. Inst.* xxiv (1892) 429, t. 37; *Cheesem. Man. N.Z. Fl.* (1906) 622.

South Island: Canterbury—Castle Hill basin, 2000–3000 ft., *J. D. Enys! T. Kirk! T. F. C.* Parasitic on *Aristotelia fruticosa*, *Discaria*, and *Coprosma*.

Family XXXII. **BALANOPHORACEAE.**

Low-growing fleshy leafless or scaly root-parasites. Stem reduced to a tuberous globular or misshapen often lobed rhizome. Peduncles short or long, thick, naked or clothed with scattered or imbricate scales. Flowers monoecious or dioecious, minute, crowded in spadix-like heads at the top of the peduncles. Male flowers: Perianth wanting or of 3–6 valvate lobes. Stamens 1–3, rarely more; filaments free or connate into a tube or column; anthers 2–many-celled. Female flowers: Perianth wanting or adnate to the ovary; limb absent or minutely toothed. Ovary ovoid or globose, 1–3-celled; styles 1–2, long or short or almost absent; stigmas simple or capitellate, sometimes sessile and discoid; ovules solitary in each cell, pendulous, anatropous. Fruit a minute crustaceous or coriaceous 1-seeded utricle or nut. Seed adherent to the pericarp, albuminous; embryo most minute.

A small but very remarkable family of fleshy root-parasites, chiefly tropical in its distribution, but nowhere plentiful. Genera, 14; species, 35.

DACTYLANTHUS Hook. f.

A root-parasite. Rhizome usually subterranean, perennial, hard and woody, rounded or amorphous, often irregularly lobed, surface rough with small tubercles or warts. Flowering stems or peduncles annual, numerous, crowded, clavate, clothed throughout with imbricate ovate or oblong brownish scales, the upper of which are larger and more closely placed, surrounding the spadices. Spadices numerous at the ends of the peduncles, slender, erect, cylindrical or slightly fusiform. Flowers very minute, densely packed, monoecious. Male flowers: Perianth wanting or of 2 minute subulate processes. Stamens 1 or 2; filaments very short; anthers didymous, 2-celled. Female flowers: Perianth adnate to the ovary; limb of 2 or 3 erect subulate segments. Ovary stipitate, ovoid-oblong, 1-celled; style long, filiform; stigma terminal; ovule solitary, apparently pendulous. Fruit minute, crustaceous.

A very distinct monotypic genus, not closely allied to any other, confined to New Zealand.

1. **D. Taylori** *Hook. f. in Trans. Linn. Soc.* xxii (1859) 425, t. 75.—Rhizome stout, varying in size according to the age of the plant, 1–12 in. diam. or more. Flowering stems 2–6 in. high, ½–1 in. diam., fleshy when

young. Scales from $\frac{1}{4}$ to $\frac{1}{2}$ in. long at the base of the peduncle, larger above, frequently 1 in. Spadices almost concealed by the upper scales, 10–30 together or more, $\frac{3}{4}$–$1\frac{1}{2}$ in. long. Flowers rather loosely placed towards the base of the spadix, very densely packed elsewhere.—*Handb. N.Z. Fl.* (1864) 255; *T. Kirk in Trans. N.Z. Inst.* xxviii (1896) 493; *Cheesem. Man. N.Z. Fl.* (1906) 625; *Ill. N.Z. Fl.* ii (1914) t. 178.

North Island: Auckland—Plateau between Hokianga and the Northern Wairoa, *P. Bedlington!* from Port Charles to Cape Colville, *H. Nairn!* forest plateau behind the Township of Thames, *T. Kirk*, *W. Townson!* East Cape district, *H. Hill!* Hawke's Bay—Runanga and Opepe, near Taupo, *H. Hill*, *T. F. C.*; Tarawera and Nuhaka, *A. Hamilton*; Hawkston and Patoka, *F. Hutchinson!* Taranaki—Mount Egmont, *W. H. Skinner*, *Petrie*, *Cockayne*. Wellington — Upper Wanganui at Pipiriki, *E. Phillips Turner*; Upper Waitotara, *J. R. Annabell!* between the Upper Wangaehu and Taupo, *Rev. R. Taylor*, *H. C. Field!* Upper Rangitikei, *J. P. Marshall*, *E. Phillips Turner*; Kaitoke, near Wellington, *J. S. Tennant* and *B. C. Aston!* Sea-level to 3500 ft. *Pua-reinga.* February–April.

Since the first edition of this work was published much additional information respecting this remarkable plant has been obtained. This I have collated and published in my "Illustrations of the N.Z. Flora" (vol. ii, t. 178), and in the Trans. N.Z. Inst. (vol. lii (1920) 12). Students should refer to these works for much matter which from the exigencies of space cannot be given here. I may mention, however, that through Mr. Townson's investigations it has been definitely proved that spadices of both sexes occur on nearly all full-sized rhizomes.

Family XXXIII. **POLYGONACEAE.**

Herbs or shrubs or woody climbers. Leaves alternate or rarely opposite, simple, entire or serrulate. Stipules thin, scarious or membranous, forming a sheath round the stem. Flowers small, regular, usually hermaphrodite, herbaceous or coloured, often jointed on the pedicel, clustered in the axils of the leaves or in spikes or racemes, often forming terminal panicles. Perianth inferior, persistent; segments 3–6, free or connate at the base, imbricate. Stamens 5–9, rarely more or less, hypogynous or perigynous; filaments capillary or subulate, free or connate at the base; anthers 2-celled. Ovary superior, compressed or 3-gonous; styles 1–3; ovule solitary, basal, orthotropous. Fruit a small hard indehiscent trigonous or compressed nut, usually enclosed in the persistent perianth. Seed erect; testa membranous; albumen copious, farinaceous; embryo variable in position, radicle superior.

A rather large family, spread over the whole world, but most abundant in the North Temperate Zone. Genera 30; species over 700. The roots of many species are nauseous and purgative, the medicinal rhubarb being a well-known instance. On the other hand, the stems and leaves are frequently acid and refreshing, as the garden-rhubarb and the common sorrel. Buckwheat (*Fagopyrum*) is the only edible plant of any consequence. Of the 3 New Zealand genera, *Muehlenbeckia* extends to Australia and South America; the remaining 2 are widely distributed in both hemispheres.

Flowers hermaphrodite. Perianth-segments 5, not succulent in fruit	1. Polygonum.
Flowers hermaphrodite. Perianth-segments 6, the 3 inner enlarging and closing over the fruit, not succulent ..	2. Rumex.
Flowers unisexual. Perianth-segments 5, enlarged and succulent in fruit	3. Muehlenbeckia.

1. **POLYGONUM** Linn.

Herbs, rarely shrubby at the base. Leaves alternate; stipules membranous, usually tubular and closely sheathing the stem. Flowers small, hermaphrodite, clustered; clusters either axillary or in racemes or spikes or panicles; bracts and bracteoles membranous, ochreate; pedicels usually jointed. Perianth 5-partite, green or coloured; segments equal or the 2 or 3 outer ones the largest. Stamens 5–8. Ovary compressed or 3-gonous; styles 2 or 3, free or connate at the base; stigmas usually capitellate. Nuts compressed or 3-gonous, included in the persistent perianth. Seed albuminous; embryo excentric or lateral; radicle long, superior.

A large and almost cosmopolitan genus, including over 175 species. The three found in New Zealand are all widely distributed.

* Stems prostrate. Flowers in axillary clusters.

Stems long, wiry, sparingly branched. Perianth $\frac{1}{8}$ in. long. Nut minutely striate or punctate .. .. 1. *P. aviculare.*
Stems short, compactly branched. Perianth $\frac{1}{12}$ in. long. Nut smooth and polished .. .. 2. P. *plebeium.*

** Stems erect or ascending above. Flowers in slender terminal spikes.

Leaves 2–5 in., lanceolate. Stipules ciliate and pilose. Spikes very slender, 1–2 in. long .. .. 3. *P. serrulatum.*

For references to several introduced species of *Polygonum*, see the list of naturalized plants appended to this work.

1. **P. aviculare** *Linn. Sp. Plant.* (1753) 362.—A glabrous rigid and wiry prostrate annual, much branched from the base; branches $\frac{1}{2}$–2 ft. long, straggling, grooved, leafy throughout. Leaves scattered, sessile or shortly petioled, $\frac{1}{3}$–1 in. long or more, linear-oblong to lanceolate or linear-lanceolate, rather broader and elliptic-oblong, acute or obtuse, veins indistinct beneath, margins flat or recurved; stipules brown or reddish near the base, silvery-white above, scarious, lacerate to below the middle. Flowers small, $\frac{1}{10}$–$\frac{1}{8}$ in. long, solitary or in clusters of 2–4 in the axils of nearly all the leaves, very shortly pedicelled. Perianth-segments oblong, obtuse, with a green centre and broad white margins. Nut ovoid, obtusely 3-gonous, very minutely striate or punctate.—*Hook. f. Fl. Nov. Zel.* i (1853) 210; *Handb. N.Z. Fl.* (1864) 235; *Benth. Fl. Austral.* v (1870) 267; *Cheesem. Man. N.Z. Fl.* (1906) 589.

North and South Islands: Roadsides and waste places from the North Cape to Foveaux Strait. Most probably an immigrant. Sea-level to 2500 ft. *Knot-grass; Makakaka.* November–March.

It is highly doubtful if this is indigenous anywhere outside Europe and northern Asia, although its present distribution is almost cosmopolitan. So far as its occurrence in New Zealand is concerned, I should certainly have relegated it to the list of naturalized plants had it not been for the positive opinion expressed in favour of its nativity by the late Mr. Kirk. Those interested in the subject should read the papers by Kirk and Travers printed in vols. iv and v of the Trans. N.Z. Inst.

2. **P. plebeium** *R. Br. Prodr.* (1810) 420.—Habit of *P. aviculare*, but smaller and more compactly branched. Stems prostrate, glabrous or minutely scaberulous, 4–12 in. long, rarely more; branches slender, grooved. Leaves more closely placed than in *P. aviculare*, $\frac{1}{6}$–$\frac{1}{2}$ in. long, linear to linear-oblong, rarely linear-spathulate, obtuse or subacute, midrib evident, margins flat or recurved; stipules short, hyaline, lacerate to the middle. Flowers small, $\frac{1}{12}$–$\frac{1}{10}$ in. long, solitary or in clusters of 2–5 in the axils of most of the leaves; pedicels short. Nut smaller than in *P. aviculare*,

See Fl. Nov. Zel. p. 430 re P. prostratum R. Br.

rhomboid, obtusely 3-gonous, smooth and shining.—*Benth. Fl. Austral.* v (1870) 267 ; *Cheesem. Man. N.Z. Fl.* (1906) 589. P. Dryandri *Spreng. Syst.* ii (1825) 255 ; *Hook. f. Fl. Nov. Zel.* i (1853) 210. P. aviculare *var.* Dryandri *Hook. f. Handb. N.Z. Fl.* (1864) 236.

North and South Islands : From the Great Barrier Island and the East Cape southwards to the Bluff, but local in the North Island, most abundant in Canterbury and Otago. Sea-level to 3000 ft. November–March.

Very closely allied to *P. aviculare*, but apparently sufficiently distinct in the smaller size and more compact habit, smaller flowers, and smaller shining and polished nut. A common plant in Australia, tropical Asia, and some parts of Africa.

3. **P. serrulatum** *Lag. Gen. et Sp. Nov.* (1816) 14. — Stems slender, herbaceous, sparingly branched, prostrate and rooting below, ascending or erect above, glabrous, 9–24 in. long or more. Leaves shortly petiolate, 2–5 in. long, lanceolate or linear-lanceolate, acuminate, narrowed to a rounded or subcordate base, membranous, glabrous or strigose on the midrib beneath, margins serrulate ; stipules long, closely sheathing, ciliate and pilose with long erect hairs. Spikes terminal, very slender, simple or sparingly branched, 1–2 in. long ; bracts narrow-turbinate, truncate, margins ciliate. Flowers 2–3 to each bract, small, reddish, $\frac{1}{12}$ in. long. Perianth-segments oblong, obtuse, glabrous and eglandular. Stamens 5 or 6. Style-branches 2, rarely 3. Nut plano-convex with obtuse margins, rarely trigonous, smooth and shining. — *Cheesem. Man. N.Z. Fl.* (1906) 589. P. minus *var.* decipiens *Hook. f. Handb. N.Z. Fl.* (1864) 235. P. prostratum *A. Rich. Fl. Nouv. Zel.* (1832) 177 (*not of R. Br.*). *A. Cunn. Leaves all radical or
... cordate or hastate at the base, entire or toothed or almost pinnatifid. Flowers hermaphrodite or less commonly unisexual, small, green, in axillary clusters or whorls, often forming simple or panicled racemes. Perianth-segments 6, the 3 inner enlarging and closing over the fruit, margins entire or toothed, midrib often tubercled. Stamens 6. Ovary 3-gonous ; styles short, filiform ; stigmas fimbriate. Nut 3-gonous, included in the enlarged inner perianth-segments, angles acute. Embryo lateral.

A large genus of over 100 species, found in all temperate and many tropical countries, and including several common weeds of cultivation. Both the New Zealand species are endemic.

Flowering stems much divaricately branched, 6–18 in. high. Inner perianth-segments without tubercles, reticulate, margins usually with long curved spines .. .. 1. *R. flexuosus.*

Flowering stems short, stout, depressed, 2–6 in. high. Inner perianth-segments tubercled ; margins entire or with 1 or 2 short teeth .. 2. *R. neglectus.*

Several species of *Rumex* from the Northern Hemisphere have been introduced into the Dominion, and are now widely diffused, the most abundant being the English "docks" *R. obtusifolius, R. crispus,* and *R. viridis ;* and the "sheeps' sorrel" *R. acetosella.* Descriptions of these will be found in any English Flora.

1. **POLYGONUM** Linn.

Herbs, rarely shrubby at the base. Leaves alternate; stipules membranous, usually tubular and closely sheathing the stem. Flowers small, hermaphrodite, clustered; clusters either axillary or in racemes or spikes or panicles; bracts and bracteoles membranous, ochreate; pedicels usually jointed. Perianth 5-partite, green or coloured; segments equal or the 2 or 3 outer ones the largest. Stamens 5–8. Ovary compressed or 3-gonous; styles 2 or 3, free or connate at the base; stigmas usually capitellate. Nuts compressed or 3-gonous, included in the persistent perianth. Seed albuminous; embryo excentric or lateral; radicle long, superior.

rhomboid, obtusely 3-gonous, smooth and shining.—*Benth. Fl. Austral.* v (1870) 267 ; *Cheesem. Man. N.Z. Fl.* (1906) 589. P. Dryandri *Spreng. Syst.* ii (1825) 255 ; *Hook. f. Fl. Nov. Zel.* i (1853) 210. P. aviculare *var.* Dryandri *Hook. f. Handb. N.Z. Fl.* (1864) 236.

North and South Islands : From the Great Barrier Island and the East Cape southwards to the Bluff, but local in the North Island, most abundant in Canterbury and Otago. Sea-level to 3000 ft. November–March.

Very closely allied to *P. aviculare*, but apparently sufficiently distinct in the smaller size and more compact habit, smaller flowers, and smaller shining and polished nut. A common plant in Australia, tropical Asia, and some parts of Africa.

3. **P. serrulatum** *Lag. Gen. et Sp. Nov.* (1816) 14. — Stems slender, herbaceous, sparingly branched, prostrate and rooting below, ascending or erect above, glabrous, 9–24 in. long or more. Leaves shortly petiolate, 2–5 in. long, lanceolate or linear-lanceolate, acuminate, narrowed to a rounded or subcordate base, membranous, glabrous or strigose on the midrib beneath, margins serrulate ; stipules long, closely sheathing, ciliate and pilose with long erect hairs. Spikes terminal, very slender, simple or sparingly branched, 1–2 in. long ; bracts narrow-turbinate, truncate, margins ciliate. Flowers 2–3 to each bract, small, reddish, $\frac{1}{12}$ in. long. Perianth-segments oblong, obtuse, glabrous and eglandular. Stamens 5 or 6. Style-branches 2, rarely 3. Nut plano-convex with obtuse margins, rarely trigonous, smooth and shining. — *Cheesem. Man. N.Z. Fl.* (1906) 589. P. minus *var.* decipiens *Hook. f. Handb. N.Z. Fl.* (1864) 235. P. prostratum *A. Rich. Fl. Nouv. Zel.* (1832) 177 (*not of R. Br.*). *A. Cunn. Precur.* (1838) n. 358 ; *Raoul Choix* (1846) 42 ; *Hook. f. Fl. Nov. Zel.* i (1853) 209.

North and South Islands, Chatham Islands : Abundant along the sides of rivers or in lowland swamps from the North Cape to Canterbury. *Tutunawai.* November–March.

A widely distributed plant, ranging through south Europe, western Asia, Africa, and Australia. It differs from *P. minus* in the larger size, the more slender and much more erect habit, and in the longer and more ciliate stipules.

2. **RUMEX** Linn. 1735.

Perennial or annual herbs, very rarely shrubby. Leaves all radical or radical and cauline, often cordate or hastate at the base, entire or toothed or almost pinnatifid. Flowers hermaphrodite or less commonly unisexual, small, green, in axillary clusters or whorls, often forming simple or panicled racemes. Perianth-segments 6, the 3 inner enlarging and closing over the fruit, margins entire or toothed, midrib often tubercled. Stamens 6. Ovary 3-gonous ; styles short, filiform ; stigmas fimbriate. Nut 3-gonous, included in the enlarged inner perianth-segments, angles acute. Embryo lateral.

A large genus of over 100 species, found in all temperate and many tropical countries, and including several common weeds of cultivation. Both the New Zealand species are endemic.

Flowering stems much divaricately branched, 6–18 in. high. Inner perianth-segments without tubercles, reticulate, margins usually with long curved spines .. .. 1. *R. flexuosus.*

Flowering stems short, stout, depressed, 2–6 in. high. Inner perianth-segments tubercled ; margins entire or with 1 or 2 short teeth .. 2. *R. neglectus.*

Several species of *Rumex* from the Northern Hemisphere have been introduced into the Dominion, and are now widely diffused, the most abundant being the English "docks" *R. obtusifolius*, *R. crispus*, and *R. viridis ;* and the "sheeps' sorrel" *R. acetosella.* Descriptions of these will be found in any English Flora.

1. **R. flexuosus** *Sol. ex Forst. f. Prodr.* (1786) n. 515.—A glabrous perennial herb with a diffusely branched stem 6–18 in. high; branches slender, grooved, flexuous, divaricate. Leaves chiefly radical, variable in size, 3–12 in. long, linear or linear-oblong, acute or obtuse, cuneate or truncate or cordate at the base, rarely expanded or subhastate; margins flat or waved. Panicle at first open, but in an advanced fruiting stage the branches are often numerous, spreading and intricate; whorls remote, 4–12-flowered, the lower ones leafy; peduncles jointed near the base, curved, deflexed. Inner segments of the fruiting-perianth about $\frac{1}{10}$ in. long, rhomboid, narrowed into a long acuminate tip, reticulated, without tubercles; margins entire or more usually furnished with 1–4 hooked spines on each side.—*Hook. f. Fl. Nov. Zel.* i (1853) 211; *Handb. N.Z. Fl.* (1864) 237; *Cheesem. Man. N.Z. Fl.* (1906) 590. R. Cunninghamii *Meissn. in DC. Prodr.* xiv (1856) 62. R. Brownianus *A. Cunn. Precur.* (1838) n. 360 (*not of Camp.*); *Raoul Choix* (1846) 42.

Kermadec Islands, North and South Islands: Abundant throughout. Sea-level to 4,000 ft. December–March.

Very closely allied to the Australian *R. Brownii*, to which it was referred by Allan Cunningham, and from which it differs mainly in the more diffusely branched habit.

2. **R. neglectus** *T. Kirk in Trans. N.Z. Inst.* ix (1877) 493.—A glabrous perennial herb 2–6 in. high; rootstock long, stout, often branched above. Leaves rosulate, 1–3 in. long, linear-oblong, obtuse, truncate or cuneate at the base, margins crenate-undulate; petiole almost as long as the blade. Flowering stem short, stout, depressed, simple or with 1–2 branches from the base; dense-flowered or rarely elongated with the whorls interrupted; peduncles usually deflexed. Flowers hermaphrodite. Fruiting perianth subcampanulate, about $\frac{1}{8}$ in. long, thickened at the base; outer segments oblong, obtuse, equalling the tube; inner rather longer, lanceolate, acute, with a tubercle on the midrib and 1 or 2 short teeth on each side.—*D. Oliver in Hook. Ic. Plant.* t. 1245; *Cheesem. Man. N.Z. Fl.* (1906) 591. R. cuneifolius *var.* alismaefolius *Hook f. Fl. Antarct.* i (1844) 67. Wall. Rec. Cant. Mus. 1935. 4:111.

North Island: Pebbly beaches near Wellington, *T. Kirk! B. C. Aston!* South Island: Canterbury—*J. B. Armstrong;* Port Molyneux, Catlin's River, Bluff, *Petrie!* Martin's Bay, *Poppelwell*: Dusky Bay, *Buchanan!* islands in Foveaux Strait, *Cockayne.* Stewart Island: Not uncommon on pebbly and sandy beaches, *Cockayne.* Auckland Island: *Hook. f., T. Kirk! Cockayne! J. S. Tennant!* November–March.

3. MUEHLENBECKIA Meissn. 1840. Nom. Cons.

Large or small shrubs or undershrubs, often climbing, sometimes prostrate or diffusely spreading. Leaves alternate, petiolate, large or small, sometimes wanting; stipules short, loosely sheathing. Flowers polygamous or dioecious, small, whitish, fascicled within small sheathing bracts; fascicles axillary or arranged in axillary or terminal spikes, racemes, or panicles. Perianth deeply 5-partite; segments equal or the outer ones rather larger, often becoming white and succulent in fruit. Stamens 8, rarely fewer, affixed to the base of the perianth; filaments filiform; anthers ovate, in the female flowers reduced to short and thick staminodia or altogether wanting. Ovary 3-gonous, in the male flowers small and rudimentary; styles 3, short; stigmas usually fimbriate. Nut obtusely or acutely 3-gonous, enclosed in the usually more or less succulent perianth.

See Mastride, Bull. Field mus. Nat. Hist. 4 (5) 1927.

In Cheeseman's Manual, page 400, is mentioned Rumex flexuosus Soland ex Forst f. Prodr. (1786) n. 515. Instead of No. n. 515 probably this should say page 90. On that page Forster attributes the name to Solander but gives no description. This is first described in Sprengel, Syst. Veg. 2: 162. 1825. The name is there attributed to Forster. Rechinger in Oesters. Bot. Zeitschr 84: 45. 1935, attributed the name to Solander, but it should have been Forster ex Sprengel, though possibly Soland ex Spreng. If this citation is to be shortened, it should then be Spreng., not Soland (see Internat. Rules, Art. 48, paragraph 2). Type collected by Banks & Solander. Rechinger has annotated U. S. Nat. Herb. specimen as "type" but probably should be "type collection" or "isotype". This specimen came from the British Museum. Presumably the type is still at the British Museum.

Leaves wanting, or, if present, linear. Male flowers in lax spikes; females in few-flowered fascicles .. .. 5. *M. ephedrioides.*

1. **M. australis** *Meissn. Gen. Comm.* (1843) 227.—A much-branched climber, covering shrubs or small trees, or trailing over cliffs or rocks; trunk stout, woody, sometimes 3 in. diam.; bark greyish; branches numerous, flexuous and interlaced, the younger ones grooved and angled, glabrous or faintly scaberulous. Leaves petiolate, 1–3 in. long, ovate or orbicular-oblong, apiculate or acuminate, rarely obtuse, cordate or truncate at the base, thin and membranous, quite glabrous, usually entire, but sometimes panduriform or 3-lobed, margins undulate-crisped; petioles $\frac{1}{3}$–1 in. long; stipules deciduous. Panicles large, axillary and terminal, much branched, $1\frac{1}{2}$–3 in. long or more. Flowers about $\frac{1}{6}$ in. diam., greenish, dioecious; males with 8 stamens and the rudiment of an ovary; females with 8 blunt staminodia and a short triquetrous ovary; stigmas broad, fimbriate. Fruiting perianth closed over the fruit, slightly succulent or almost herbaceous. Nut black, shining, 3-angled and 3-grooved, angles often twisted.—*Cheesem. Man. N.Z. Fl.* (1906) 592. M. adpressa *Hook. f. Handb. N.Z. Fl.* (1864) 236 (*not of Meissn.*). Polygonum australe *A. Rich. Fl. Nouv. Zel.* (1832) 178; *A. Cunn. Precur.* (1838) n. 355; *Hook f. Fl. Nov. Zel.* i (1853) 210; *Raoul Choix* (1846) 42. P. adpressum *A. Cunn. l.c.* (1838) n. 356 (*not of Labill.*). Coccoloba australis *Forst. f. Prodr.* (1786) n. 176.

North and South Islands, Stewart Island, Chatham Islands: Common from the Three Kings Islands and the North Cape southwards. Sea-level to 2000 ft. November–April.

Also found in Norfolk Island, and very closely allied to the Australian *M. adpressa* Meissn.

2. **M. Astoni** *Petrie in Trans. N.Z. Inst.* xliii (1911) 257, t. 2.—A much-branched shrub, forming erect masses 4–6 ft. high and almost as much in diameter; composed of numerous flexuous and interlacing zigzag branches mixed with cane-like woody shoots $\frac{1}{4}$–$\frac{1}{3}$ in. diam. Branches dark-brown or reddish-brown, glabrous; bark furrowed or wrinkled. Leaves in fascicles of 2–3 on short lateral branchlets, small, $\frac{1}{4}$–$\frac{1}{3}$ in. long, rarely more; petiole about $\frac{1}{2}$ the length; blade broadly obcordate, thin and membranous, quite entire; veins indistinct. Flowers minute, in fascicles of 2–4 at the tips of the branchlets. Peduncles very short, sometimes almost wanting. Ripe fruit not seen.

North Island: Coast near Cape Turakirae, Cook Strait, Palliser Bay, *B. C. Aston! Petrie! T. F. C.* South Island: River-flats by the Awatere River, near Seddon, *B. C. Aston!*

A very distinct and peculiar species, quite unlike any other.

3. MUEHLENBECKIA Meissn. 1840. Mon. Cons

Large or small shrubs or undershrubs, often climbing, sometimes prostrate or diffusely spreading. Leaves alternate, petiolate, large or small, sometimes wanting; stipules short, loosely sheathing. Flowers polygamous or dioecious, small, whitish, fascicled within small sheathing bracts; fascicles axillary or arranged in axillary or terminal spikes, racemes, or panicles. Perianth deeply 5-partite; segments equal or the outer ones rather larger, often becoming white and succulent in fruit. Stamens 8, rarely fewer, affixed to the base of the perianth; filaments filiform; anthers ovate, in the female flowers reduced to short and thick staminodia or altogether wanting. Ovary 3-gonous, in the male flowers small and rudimentary; styles 3, short; stigmas usually fimbriate. Nut obtusely or acutely 3-gonous, enclosed in the usually more or less succulent perianth.

See Maskvide, Bull. Field mus. Nat. Hist. 4 (5) 1927.

A small genus of about 15 species, found in Australia, New Zealand, the Pacific islands, and extra-tropical and Andine South America. Of the four species described below, one is found in Australia and another in Norfolk Island, the remaining two are endemic.

Leaves 1–3 in., broad-ovate, acuminate, membranous. Flowers in much-branched panicles	1. *M. australis.*
An erect densely branched shrub. Leaves small, $\frac{1}{4}$–$\frac{1}{3}$ in. Flowers minute, in fascicles of 2–4	2. *M. Astoni.*
Leaves $\frac{1}{5}$–$\frac{3}{4}$ in., broadly oblong or orbicular. Flowers in spikes, rarely panicled	3. *M. complexa.*
A small prostrate shrub. Leaves $\frac{1}{10}$–$\frac{1}{8}$ in., ovate-oblong or orbicular. Flowers solitary or 2 together	4. *M. axillaris.*
Leaves wanting, or, if present, linear. Male flowers in lax spikes; females in few-flowered fascicles	5. *M. ephedrioides.*

1. **M. australis** (Forst. f.) *Meissn. Gen. Comm.* (1843) 227.—A much-branched climber, covering shrubs or small trees, or trailing over cliffs or rocks; trunk stout, woody, sometimes 3 in. diam.; bark greyish; branches numerous, flexuous and interlaced, the younger ones grooved and angled, glabrous or faintly scaberulous. Leaves petiolate, 1–3 in. long, ovate or orbicular-oblong, apiculate or acuminate, rarely obtuse, cordate or truncate at the base, thin and membranous, quite glabrous, usually entire, but sometimes panduriform or 3-lobed, margins undulate-crisped; petioles $\frac{1}{3}$–1 in. long; stipules deciduous. Panicles large, axillary and terminal, much branched, $1\frac{1}{2}$–3 in. long or more. Flowers about $\frac{1}{6}$ in. diam., greenish, dioecious; males with 8 stamens and the rudiment of an ovary; females with 8 blunt staminodia and a short triquetrous ovary; stigmas broad, fimbriate. Fruiting perianth closed over the fruit, slightly succulent or almost herbaceous. Nut black, shining, 3-angled and 3-grooved, angles often twisted.—*Cheesem. Man. N.Z. Fl.* (1906) 592. M. adpressa *Hook. f. Handb. N.Z. Fl.* (1864) 236 (*not of Meissn.*). Polygonum australe *A. Rich. Fl. Nouv. Zel.* (1832) 178; *A. Cunn. Precur.* (1838) n. 355; *Hook f. Fl. Nov. Zel.* i (1853) 210; *Raoul Choix* (1846) 42. P. adpressum *A. Cunn. l.c.* (1838) n. 356 (*not of Labill.*). Coccoloba australis *Forst. f. Prodr.* (1786) n. 176.

M. delicis Petrie 1926. Chiefs

North and South Islands, Stewart Island, Chatham Islands: Common from the Three Kings Islands and the North Cape southwards. Sea-level to 2000 ft. November–April.

Also found in Norfolk Island, and very closely allied to the Australian *M. adpressa* Meissn.

2. **M. Astoni** *Petrie in Trans. N.Z. Inst.* xliii (1911) 257, t. 2.—A much-branched shrub, forming erect masses 4–6 ft. high and almost as much in diameter; composed of numerous flexuous and interlacing zigzag branches mixed with cane-like woody shoots $\frac{1}{4}$–$\frac{1}{3}$ in. diam. Branches dark-brown or reddish-brown, glabrous; bark furrowed or wrinkled. Leaves in fascicles of 2–3 on short lateral branchlets, small, $\frac{1}{4}$–$\frac{1}{3}$ in. long, rarely more; petiole about $\frac{1}{2}$ the length; blade broadly obcordate, thin and membranous, quite entire; veins indistinct. Flowers minute, in fascicles of 2–4 at the tips of the branchlets. Peduncles very short, sometimes almost wanting. Ripe fruit not seen.

North Island: Coast near Cape Turakirae, Cook Strait, Palliser Bay, *B. C. Aston! Petrie! T. F. C.* South Island: River-flats by the Awatere River, near Seddon, *B. C. Aston!*

A very distinct and peculiar species, quite unlike any other.

Calacinum complexa (A. Cunn.) Meisn.

3. **M. complexa** *Meissn. Gen. Comm.* (1843) 227. — Forming dense thick and elastic prostrate masses many feet in diam., or climbing over bushes or rocks. Stems slender, tough and woody, much interlaced; branches very numerous, flexuous, terete, the ultimate ones pubescent with short stiff hairs; bark dark red-brown. Leaves petiolate, exceedingly variable in size and shape, even on the same plant, $\frac{1}{5}$–$\frac{3}{4}$ in. long or more, broadly oblong or obovate or orbicular, rounded or retuse at the tip, rarely subacute, cordate or truncate or rounded at the base, often contracted in the middle, quite smooth, glabrous or the petiole puberulous, coriaceous or almost membranous, margins even, entire; stipules deciduous. Spikes axillary and terminal, long or short, simple or compound, glabrous or puberulous, sometimes reduced to 2 or 3 flowers, at other times forming a panicle 1–1½ in. long or more. Flowers small, dioecious. Stamens 8. Stigmas very broad, fimbriate. Fruiting-perianth much enlarged, often $\frac{1}{4}$–$\frac{1}{3}$ in. diam., succulent, waxy-white, forming a fleshy cup surrounding the fruit, in some varieties unaltered and herbaceous. Nut black, shining, deeply triquetrous.—*Hook. f. Handb. N.Z. Fl.* (1864) 236; *Cheesem. Man. N.Z. Fl.* (1906) 592. M. paucifolia *Col. in Trans. N.Z. Inst.* xxi (1889) 99. M. truncata *Col. l.c.* xxi (1889) 101. Polygonum complexum *A. Cunn. Precur.* (1838) n. 357; *Raoul Choix* (1846) 42; *Hook. f. Fl. Nov. Zel.* i (1853) 210.

Var. **grandifolia** *H. Carse in Trans. N.Z. Inst.* xlviii (1916) 239.—Size and habit of *M. australe*, but ultimate branches terete and densely pubescent. Leaves almost as large as those of *M. australe*, but texture nearer that of *M. complexa*.

(C. E.)

Var. **microphylla** *Cockayne* in *Trans. N.Z. Inst.* xlviii (1916) 208.—Forming round-topped elastic bushes with the habit of *M. complexa*, but leaves very much smaller, $\frac{1}{20}$–$\frac{1}{10}$ in. long, variable in shape. — M. microphylla *Col. in Trans. N.Z. Inst* xx (1888) 204.

Var. **trilobata** *Cheesem. n. var.* — Leaves regularly and distinctly trilobate or panduriform. M. trilobata *Col. in Trans. N.Z. Inst.* xxi (1889) 100.

North and South Islands, Stewart Island: Abundant throughout, ascending to 2000 ft. *Pohuehue.* November–April.

Varying much in the size and shape of the leaves, the degree of development of the spikes, and the extent to which the perianth enlarges and becomes fleshy in fruit. Mr. Colenso made no less than 4 species, based mainly on variations in the above characters, but his own specimens show how inconstant these distinctions are, and how little they can be relied upon. The four varieties characterized above appear to have the range of the species, except Mr. Carse's var. *grandifolia*, which I only know from Mongonui County.

(Hook. f.)

4. **M. axillaris** *Walp. Ann.* i (1853) 552.—A small much-branched prostrate or diffuse shrubby plant, usually forming densely matted patches 3–12 in. diam., but sometimes open and straggling; stems and branches woody; branchlets puberulous. Leaves on rather long petioles, small, $\frac{1}{10}$–$\frac{1}{3}$ in. long, broadly oblong or ovate-oblong or almost orbicular, obtuse or retuse, rounded at the base, flat, quite glabrous, dotted beneath. Flowers small, solitary or 2 together in the axils of the leaves, or the males rarely forming short few-flowered spikes at the ends of the branchlets; pedicels slender. Stigmas fimbriate. Perianth succulent in fruit or almost unaltered. Nut triquetrous with obtuse angles, black, smooth and shining, rather longer than the perianth.—*Hook. f. Handb. N.Z. Fl.* (1864) 236; *Benth. Fl. Austral.* v (1870) 275; *Cheesem. Man. N.Z. Fl.* (1906) 593; *Ill. N.Z. Fl.* ii (1914) t. 165. M. hypogea *Col. in Trans. N.Z. Inst.* xxi (1889) 98. Polygonum axillare *Hook. f. Fl. Nov. Zel.* i (1853) 211.

M. complexa x ephedroides } T.N.Z.I. 57:70
M. axillaris x "

North Island: Mountain districts in the interior, from Taupo and the East Cape southwards. South Island: Common in mountain districts throughout. Sea-level to 4500 ft. December–March.

Also found in Tasmania and Australia, and reported from Lord Howe Island.

5. **M. ephedrioides** *Hook. f. Fl. Nov. Zel.* i (1853) 211. — A much-branched prostrate shrub; stems 9–36 in. long or more, rigid and wiry, deeply grooved, leafless and rush-like or sparingly leafy; branchlets often scaberulous. Leaves when present few and scattered, petiolate or almost sessile, $\frac{1}{6}$–1 in. long, linear or linear-lanceolate, often dilated or almost hastate at the base, acute or obtuse, glabrous, sometimes scaberulous on the midrib beneath; stipules short, obliquely truncate. Flowers small, polygamous; those on the male plant in lax axillary simple or branched glabrous spikes, often with a few female flowers intermixed; on the female plant in few-flowered fascicles or short dense spikes, usually with 1 or 2 male flowers mixed with the females. Stigmas fimbriate. Perianth succulent or remaining unaltered in fruit. Nut exceeding the perianth, black, smooth and shining, triquetrous with the angles obtuse.—*Handb. N.Z. Fl.* (1864) 237; *Cheesem. Man. N.Z. Fl.* (1906) 593.

Var. **muricatula.** — Smaller and much more slender, branchlets often almost filiform. Leaves usually present, $\frac{1}{6}$–$\frac{1}{2}$ in. long, linear. Perianth-segments membranous in fruit.—M. muricatula *Col. in Trans. N.Z. Inst.* xxii (1890) 482 (perhaps a distinct species). = X. muricata Cheesem. & Allan.

North Island: Hawke's Bay—Near the sea, *Colenso! A. Hamilton!* Cook Strait, *B. C. Aston! T. F. C.;* Upper Rangitikei, *Bishop Williams, Petrie!* South Island: Marlborough—Near Blenheim, *Buchanan! T. Kirk!* Canterbury—Waipara, *Haast!* near the mouth of the Rakaia River, *Cockayne.* Otago—Lower Waitaki, *Hector* and *Buchanan;* Kurow, Awamoko, Roxburgh, *Petrie!* Var. *muricatula:* North Island—Lake Taupo, *Tryon! T. F. C.;* Ruapehu, *H. Hill!* Waipawa, *A. Hamilton!* Sea-level to 3000 ft. December–March.

Easily recognized by the prostrate rush-like stems, which are often entirely leafless.

Family XXXIV. **CHENOPODIACEAE.**

Annual or perennial herbs or shrubs, usually succulent and fleshy, sometimes covered with a mealy scurf. Leaves alternate or very rarely opposite, simple, sometimes wanting, exstipulate. Flowers small, regular, hermaphrodite or unisexual, often dimorphic, variously disposed but usually sessile and clustered, clusters often aggregated into dense or interrupted spikes or panicles. Bracts often wanting, when present herbaceous, not scarious. Perianth inferior, 3–5-lobed or -cleft, herbaceous, persistent, imbricate. Stamens 4–5, rarely fewer, hypogynous or perigynous; filaments subulate or filiform; anthers 2-celled. Ovary superior, 1-celled; style-branches 2–3, either free or united at the base; ovule solitary, basal or lateral, amphitropous. Fruit usually a utricle, rarely a berry, enclosed in the persistent perianth, which is often enlarged or fleshy. Seed horizontal or vertical; testa crustaceous; albumen present and farinaceous or wanting embryo curved or annular or spiral.

A widely spread family, found in all climates, but most plentiful in maritime or saline localities. Genera 80; species between 500 and 600, often difficult of discrimination. The order includes the sugar-beet and mangold, two plants of great commercial importance; also the garden-beet, the spinach, and orache. Many of the species are

see Allan 1939 (VIII) 5-11. J. Bot. Lon.

common weeds of cultivation, and several of these have become naturalized in New Zealand. Of the 6 indigenous genera, 5 are widely spread in temperate and tropical climates, the remaining one (*Rhagodia*) is confined to Australia and New Zealand.

A. Stems leafy, not jointed. Stamens 3–5.

Flowers hermaphrodite or unisexual. Perianth hardly enlarged in fruit. Fruit a berry. Embryo annular	1. RHAGODIA.
Flowers usually hermaphrodite. Perianth hardly enlarged in fruit. Fruit a dry utricle. Embryo annular	2. CHENOPODIUM.
Flowers unisexual; females enclosed within 2 bracts which are much enlarged in fruit. Embryo annular	3. ATRIPLEX.
Leaves fleshy, semiterete. Perianth simply enlarged and fleshy in fruit. Embryo spiral	5. SUAEDA.
Leaves fleshy, pungent-pointed. Perianth enlarged and winged in fruit. Embryo spiral	6. SALSOLA.

B. Stems jointed apparently, leafless. Stamens 1 or 2.

Flowers sunk in cavities between the joints	4. SALICORNIA.

1. **RHAGODIA** R. Br. (& 10

Shrubs or more rarely herbs. Leaves alternate or subopposite, sessile or petiolate. Flowers small, hermaphrodite or monoecious, rarely dioecious, sessile or very shortly pedicelled, in axillary clusters or in terminal spikes or panicles; bracts wanting. Perianth 5-lobed or -partite; segments obtuse, concave, hardly enlarged in fruit. Stamens 5 or fewer, inserted at the base of the perianth; filaments subulate, flattened. Ovary subglobose; styles 2 or very rarely 3, linear or subulate. Fruit a small globose or depressed-globose berry, free from the perianth. Seed horizontal, flattened; testa crustaceous; embryo annular, surrounding the copious mealy albumen.

A small genus of 11 species, all Australian, but one of them found in New Zealand as well.

R. triandra (Forst. f.) Allan 1938. err. det.

1. **R. nutans** *R. Br. Prodr.* (1810) 408.—A much-branched prostrate or procumbent herb, green or the young leaves and branches more or less clothed with white mealy tomentum; stems 9–24 in. long, usually hard and woody at the base. Leaves opposite and alternate, petiolate, ¼–1 in. long, lanceolate or oblong-lanceolate or hastate, acute, cuneate or truncate or cordate at the base, entire, rather thin. Flowers minute, polygamous or dioecious, arranged in short loose-flowered spikes or panicles in the upper axils or terminating the branches. Perianth-segments ovate, obtuse, mealy-tomentose. Male flowers usually with 3 stamens; female flowers with 1 or 2 abortive stamens. Ovary depressed-globose; styles 2. Fruit globose, fleshy, bright-red, ⅛ in. diam.—*Benth. Fl. Austral.* v (1875) 156; *Cheesem. in Trans. N.Z. Inst.* xvi (1884) 408; *Man. N.Z. Fl.* (1906) 578.

KERMADEC ISLANDS, NORTH ISLAND: Rocky places near the sea, not uncommon. SOUTH ISLAND: Sea-cliffs near Cape Foulwind, *W. Townson!* Queen Charlotte Sound, *J. H. Macmahon!* Kaikoura Peninsula, *Spencer!* Banks Peninsula, *R. M. Laing, A. Wall;* near the mouth of the Ashburton River, *H. H. Allan!* Probably abundant on rocky coasts. Inland on island in the Waiau River, near Marble Point, *C. E. Christensen.*

Closely resembles *Chenopodium triandrum* in habit and foliage, and is easily mistaken for it in the absence of fruit. Plentiful along the coast of eastern Australia, from Queensland southwards.

2. **CHENOPODIUM** Linn. 1735.

Annual or perennial erect or prostrate herbs, rarely woody at the base, mealy or glandular-pubescent, seldom glabrous. Leaves alternate, entire or lobed or toothed. Flowers minute, greenish, usually hermaphrodite, sessile in clusters; clusters axillary or in terminal spikes or panicles. Perianth 5-partite, rarely 3–4-partite; segments obtuse, incurved and concave, not at all or very slightly altered in fruit. Stamens 5 or fewer; filaments filiform or flattened, sometimes connate at the base. Ovary depressed or ovoid, styles 2–3, free or united at the base. Fruit an ovoid or depressed membranous utricle, wholly or partially included in the persistent perianth. Seed horizontal or vertical; testa crustaceous; embryo annular, enclosing the copious mealy albumen.

A widely distributed genus of from 60 to 80 species, most abundant in temperate climates. Of those described below, three are common in many parts of the world as weeds of cultivation or wayside plants, and may not be true natives of New Zealand.

* Seed horizontal (rarely vertical in *C. glaucum*).

Intensely foetid, prostrate or decumbent, mealy-pulverulent. Leaves $\frac{1}{6}$–$\frac{1}{2}$ in., triangular-hastate, entire. Flowers in small dense axillary clusters .. .. 1. *C. detestans.*

Prostrate or trailing, often glaucous, mealy-pulverulent. Leaves $\frac{1}{4}$–1 in., triangular-oblong or hastate, entire. Flowers in lax axillary or terminal spikes or panicles .. .. .. 2. *C. triandrum.*

Prostrate, fleshy. Leaves $\frac{1}{2}$–$1\frac{1}{2}$ in., oblong or deltoid, sinuate-lobed, mealy beneath. Flowers in axillary or terminal spikes .. 3. *C. glaucum.*

Erect or spreading, green or slightly mealy. Leaves $\frac{3}{4}$–$1\frac{1}{2}$ in., triangular or rhomboid, toothed or lobed. Flowers in axillary or terminal spikes or panicles .. .. 4. *C. urbicum.*

Erect; aromatic, glandular-pubescent, not mealy. Leaves 1–4 in., ovate-lanceolate, sinuate-toothed. Flowers very numerous, in slender axillary spikes .. .. 5. *C. ambrosioides.*

** Seed vertical.

Glandular-pubescent. Stems 6–18 in., decumbent below, erect above. Leaves $\frac{1}{4}$-$\frac{3}{4}$ in., oblong, sinuate-lobed or pinnatifid. Flowers in dense axillary fascicles .. .. 6. *C. carinatum.*

Small, glandular-pubescent, much branched, prostrate, 2–6 in. long. Leaves $\frac{1}{10}$-$\frac{1}{3}$ in., broadly oblong or orbicular, obscurely sinuate. Flowers in axillary glomerules .. .. 7. *C. pusillum.*

1. **C. detestans** *T. Kirk in Trans. N.Z. Inst.* ix (1877) 550.—A much-branched prostrate or decumbent herb, more or less clothed with a whitish granular meal, and with a strong and offensive odour of stale fish; branches numerous from the root, slender, spreading, 6–18 in. long. Leaves on slender petioles; blade $\frac{1}{6}$–$\frac{1}{2}$ in. long, rarely more, triangular-hastate or rhomboid-ovate, acute, cuneate at the base, entire or with a single tooth on each side. Flowers small, abundantly produced, in dense oblong or globose axillary fascicles, often becoming leafy spikes at the tips of the branches. Perianth-segments 4 or 5, oblong, obtuse, membranous, not completely concealing the fruit. Stamens usually 4. Utricle small, horizontal, depressed, brownish-black, minutely punctulate.—*Cheesem. Man. N.Z. Fl.* (1906) 579.

South Island: Canterbury—Broken River basin, *J. D. Enys! T. Kirk! T. F. C.*; Lake Coleridge, *J. D. Enys!* Otago—Lakes Wanaka and Hawea, *T. Kirk! Petrie!* Maniototo Plain, Cromwell, and other localities in the north and central portions of the province, *Petrie!* 1000–3000 ft. January–March.

Closely allied to the northern *C. vulvaria* Linn., but a smaller plant with smaller often hastate leaves, and with the flowers in dense globose fascicles. It has been recorded from Australia by Dr. J. Murray.

? See Skottsb. Suaveae Weddel. gal. Bot. Tiedy 1134.

See Trans. 72: 324.

2. **C. triandrum** *Forst. f. Prodr.* (1786) n. 129. — A much-branched prostrate or trailing herb, pale-green, glabrous or more or less mealy-tomentose; stems slender, 6–18 in. long, sometimes almost woody at the base. Leaves opposite or alternate, petiolate, ¼–1 in. long, very variable in shape, broadly oblong or orbicular to broadly triangular-hastate, obtuse or rounded at the tip, cuneate or rounded or truncate at the base, thin and membranous, green and glabrous or slightly mealy; petioles slender. Flowers very minute, farinose, in axillary or terminal lax-flowered spikes or panicles. Perianth-segments 4, oblong, obtuse. Stamens 2–4. Styles 2–3. Utricle depressed, more or less covered by the persistent perianth. Seed horizontal, minutely punctate, adherent to the utricle.—*A. Rich. Fl. Nouv. Zel.* (1832) 212; *A. Cunn. Precur.* (1838) n. 361; *Raoul Choix* (1846) 43; *Hook. f. Fl. Nov. Zel.* i (1853) 212; *Handb. N.Z. Fl.* (1864) 230; *Cheesem. Man. N.Z. Fl.* (1906) 580; *Ill. N.Z. Fl.* ii (1914) t. 164.

North and South Islands: From the North Cape southwards to Foveaux Strait, not uncommon near the sea, rare and local inland. November-March.

3. **C. glaucum** *Linn. Sp. Plant.* (1753) 220. — A much-branched prostrate fleshy and succulent annual herb; branches widely spreading, flaccid, glabrous, striate, 4–18 in. long, rarely ascending at the tips. Leaves petiolate, the lower ones ½–1½ in. long, oblong-lanceolate to ovate-oblong or rhomboid, usually obtuse at the tip, cuneate at the base, coarsely and angularly sinuate-toothed or -lobed, fleshy when fresh, thin when dry, green and glabrous above, white with mealy down beneath; upper ones smaller and narrower and more entire. Flowers small, in little clusters arranged in simple or compound axillary or terminal spikes, which are usually more or less farinose. Fruiting-perianth 3–5-partite; segments short, obtuse, appressed to the fruit but not altogether concealing it. Seed horizontal or occasionally vertical, smooth, margins obtuse.—*A. Cunn. Precur.* (1838) n. 363; *Raoul Choix* (1846) 43; *Hook. f. Fl. Nov. Zel.* i (1853) 213; *Handb. N.Z. Fl.* (1864) 230; *Benth. Fl. Austral.* v (1870) 161; *Cheesem. Man. N.Z. Fl.* (1906) 580. C. ambiguum *R. Br. Prodr.* (1810) 407.

North and South Islands, Stewart Island: Common throughout in muddy or sandy places near the sea, also occasionally found in saline localities inland. November–March.

Also occurs in Australia and Tasmania, and common in many parts of Europe and temperate Asia, &c. The New Zealand and Australian plant is sometimes kept as a separate variety or species (*C. ambiguum* R. Br.), but the differences appear to be slight and inconstant.

4. **C. urbicum** *Linn. Sp. Plant.* (1753) 218.—A coarse erect or spreading branching herb 1–2 ft. high or more, green and glabrous or rarely slightly mealy; stem angled, grooved. Lower leaves on slender petioles ½–1 in. long; blade ¾–1½ in., triangular or rhombic-ovate, coarsely and irregularly toothed and lobed, rather thin, green on both surfaces, veined; upper smaller, narrower, more acute. Flowers small, in little clusters arranged in dense leafless axillary spikes, or in terminal panicles which are leafy below. Stamens 5, exserted. Styles short. Fruiting-perianth $\frac{1}{15}$ in. diam.; segments obtuse, not completely covering the utricle. Seed horizontal, much depressed, minutely punctulate, margins obtuse.—*Hook. f. Fl. Nov. Zel.* i (1853) 213; *Handb. N.Z. Fl.* (1864) 230; *Cheesem. Man. N.Z. Fl.* (1906) 581.

North Island: East Coast, *Colenso!* Has also appeared as a naturalized plant near Wellington. South Island: Not uncommon, especially in South Canterbury and Otago. Sea-level to 1000 ft. December–March.

A common European weed, which has become naturalized in North America and some other countries. It is probably not a true native of New Zealand.

5. **C. ambrosioides** *Linn. Sp. Plant.* (1753) 219.—An erect much-branched strong-smelling glandular annual herb 1–3 ft. high; branches slender, strict, leafy. Leaves shortly petiolate, 1–4 in. long, ovate- or

erect, ovate, compressed, the pericarp not adhering to the seed.—*Cheesem. Man. N.Z. Fl.* (1906) 582. C. pumilio *Hook. f. Fl. Nov. Zel.* i (1853) 214 (*not of R. Br.*).

North Island: Sandy shores of the east coast and Lake Taupo, *Colenso!* South Island: Near Nelson, *Captain F. W. Hutton!* Lake Lyndon (Canterbury), *J. D. Enys! T. Kirk! T. F. C.* Sea-level to 2500 ft.

I have had no opportunity of comparing this with the closely allied *C. pumilio* R. Br. from Australia. According to Hooker, it is mainly distinguished by the membranous perianth-segments.

3. **ATRIPLEX** Linn.

Herbs or shrubs, usually more or less mealy or scurfy-tomentose. Leaves alternate or rarely opposite. Flowers unisexual, usually in clusters arranged in simple or panicled spikes, the sexes distinct or mixed in the clusters. Male flowers ebracteate. Perianth 3–5-partite; segments oblong or obovate, obtuse. Stamens 3–5. Female flowers 2-bracteate; bracts small at first, erect and appressed, distinct or more or less connate, enlarged in fruit and forming a variously shaped 2-valved covering to the utricle. Perianth wanting or very rarely of 2–5 hyaline segments. Ovary small; styles 2, filiform. Utricle entirely concealed within the base of the greatly enlarged and thickened bracts; pericarp thin, membranous. Seed compressed, vertical or very rarely horizontal; testa thin, crustaceous or coriaceous; embryo annular, surrounding the copious mealy albumen.

A large genus of about 120 species, widely spread through most parts of the globe, but chiefly along sea-coasts or in saline localities. One of the New Zealand species is a weed of probably northern origin, two others are found in Australia, the fourth is endemic.

Erect branching shrub 1–4 ft. high, white with scurfy tomentum. Leaves 1–2 in., oblong, entire. Fruiting-bracts ¼ in., ovate-rhomboid	1. *A. cinerea.*
Erect or diffuse annual 1–2 ft. high, green or sparingly mealy. Leaves 1–3 in., lanceolate to deltoid, entire or toothed. Fruiting-bracts $\frac{1}{10}$–⅛ in., ovate-rhomboid	2. *A. patula.*
Prostrate, much branched, 3–9 in. diam., white with scurfy tomentum. Leaves ⅛–⅓ in., oblong to orbicular, entire or sinuate. Fruiting-bracts ovoid, very minute	3. *A. Buchanani.*
Prostrate, glabrous, fleshy, clothed with watery papillae, 6–18 in. long. Leaves ¼–¾ in., oblong, entire or toothed. Fruiting-bracts urceolate. Utricle transverse to the bracts, not parallel ..	4. *A. Billardieri.*

Nephrosia ulbrichiana Pflanzenfam. 520.

1. **A. cinerea** (*Poir.*) *Encycl. Suppl.* i (1810) 471.—A small branching shrub 1–4 ft. high, clothed in all its parts with densely appressed white or grey scurfy tomentum; stem woody; branches stout, angled, leafy. Leaves 1–2 in. long, linear-oblong or lanceolate, obtuse, narrowed into a short petiole, quite entire, midrib prominent beneath. Flowers dioecious or almost so; males in dense many-flowered simple or branched oblong spikes, which are often panicled at the ends of the branches. Females in small axillary clusters on the female plant, with occasionally 1 or 2 solitary in the axils of the upper leaves of the male plant. Fruiting-bracts greatly enlarged, about ¼ in. long, broadly ovate-rhomboid, subacute; disc thick and corky, swollen over the utricle, smooth or rarely tuberculate; margins thin. Utricle compressed, at the base of the bracts.—*Hook. f. Fl. Nov. Zel.* i (1853) 214; *Handb. N.Z. Fl.* (1864) 232; *Benth. Fl. Austral.* v (1870) 171; *Cheesem. Man. N.Z. Fl.* (1906) 583.

NORTH ISLAND: Wellington—Sandy shores of Palliser Bay, *Colenso!* SOUTH ISLAND: Vicinity of Nelson, *P. Lawson!* Also recorded from Canterbury, but I have seen no specimens from thence.

A common plant in many parts of Australia and Tasmania, and very closely allied to the European and African *A. Halimus* Linn.

2. **A. patula** *Linn. Sp. Plant.* (1753) 1053.—A very variable erect or decumbent or prostrate annual herb 1–2 ft. high, green and smooth, ...eolate to ... sinuate- ...ometimes ...er slender ...d female ...e axillary ...omboid or ... entire.— ...2; *Benth.*

greatly enlarged, about $\frac{1}{4}$ in. long,
disc thick and corky, swollen over the utricle, smooth
margins thin. Utricle compressed, at the base of the bracts.—*Hook. f. Fl. Nov. Zel.* i (1853) 214; *Handb. N.Z. Fl.* (1864) 232; *Benth. Fl. Austral.* v (1870) 171; *Cheesem. Man. N.Z. Fl.* (1906) 583.

North Island: Wellington—Sandy shores of Palliser Bay, *Colenso!* South Island: Vicinity of Nelson, *P. Lawson!* Also recorded from Canterbury, but I have seen no specimens from thence.

A common plant in many parts of Australia and Tasmania, and very closely allied to the European and African *A. Halimus* Linn.

2. **A. patula** *Linn. Sp. Plant.* (1753) 1053.—A very variable erect or decumbent or prostrate annual herb 1–2 ft. high, green and smooth, or sparingly mealy-white. Leaves petiolate, 1–3 in. long, lanceolate to broadly triangular-hastate, acute or obtuse, entire or coarsely sinuate-toothed; the uppermost often smaller and linear, the lowest sometimes opposite. Flowers small, monoecious, in clusters arranged in rather slender spikes, often forming narrow terminal panicles; the male and female flowers mixed or occasionally some of the females form separate axillary clusters. Male perianth small, 5-partite. Fruiting-bracts ovate-rhomboid or deltoid, acute, the disc smooth or tubercled; margins toothed or entire.—*Hook. f. Fl. Nov. Zel.* i (1853) 215; *Handb. N.Z. Fl.* (1864) 232; *Benth. Fl. Austral.* v (1870) 173; *Cheesem. Man. N.Z. Fl.* (1906) 584.

North and South Islands: Not uncommon in brackish-water swamps and other places near the sea from the Thames River southwards. December–March.

Now plentiful in almost all temperate parts of the world, either native or naturalized. How far it is indigenous in Australia and New Zealand is now very difficult to determine. The broad-leaved form known as var. *hastata* is the one most generally seen, but the more slender var. *littoralis* is also met with.

3. **A. Buchanani** *T. Kirk ex Cheesem. Man. N.Z. Fl.* (1906) 584.—An excessively branched prostrate herb, forming broad depressed greyish-white patches 3–9 in. across; stem woody at the base; branchlets slender, wiry, terete. Leaves shortly petiolate or almost sessile, $\frac{1}{8}$–$\frac{1}{3}$ in. long, oblong or oblong-ovate to suborbicular, rounded at the tip, quite entire, both surfaces densely clothed with white scurfy tomentum. Flowers minute, monoecious. Males in few-flowered clusters in the axils of the upper leaves or terminal, sometimes solitary. Perianth densely farinose, 5-partite; segments oblong, obtuse, incurved at the tip. Stamens 5, exserted; filaments filiform. Females solitary or in clusters of 2–5 in the lower axils, occasionally a few females at the base of the male clusters. Fruiting-bracts connate into an ovoid or almost urceolate 2-lipped cup. Utricle suborbicular, compressed, sunk within the base of the bracts.—Chenopodium Buchanani *T. Kirk in Trans. N.Z. Inst.* xxii (1898) 447, t. 32, f. 1.

Var. **tenuicaulis** *Petrie in Trans. N.Z. Inst.* xlvii (1915) 54.—Stems slender, erect or ascending, sparingly branched, 5–8 in. high, farinose above. Leaves few, distant, longer and narrower than in the type.

North Island: Sea-cliffs near Wellington, *Buchanan! T. Kirk!* South Island: Marlborough—The Brothers Rocks, *Robson!* Canterbury—Near the mouth of the Rangitata, *J. D. Enys!* Otago—Green Island and cliffs on the east coast, *Petrie!* saline places in the interior, Maniototo Plains, Ida Valley, Cromwell, *Petrie!* Sea-level to 1800 ft. December–March. Var. ***tenuicaulis:*** Centre Island (Foveaux Strait), *T. Kirk!* mouth of the Oreti River, *J. Crosby Smith!*

4. **A. crystallina** *Hook. f. in Lond. Journ. Bot.* vi (1847) 279.—A much-branched glabrous and succulent prostrate herb, everywhere covered with shining watery papillae; branches 6–18 in. long, spreading on all sides. Leaves shortly petiolate, $\frac{1}{4}$–$\frac{3}{4}$ in. long, oblong or obovate, obtuse, entire or sinuate-toothed, very thick and fleshy. Flowers small, monoecious.

Males fascicled at the tips of the branches, ebracteate. Perianth 5-partite; segments oblong, obtuse. Stamens 5, exserted; filaments filiform, connate at the very base. Females solitary or 2 together in the axils of the cauline leaves, minute, sessile. Fruiting-bracts combined into a shortly 2-lipped fleshy urceolate cup. Perianth wanting. Styles 2, filiform. Utricle included within the bracts, orbicular, compressed, its edges opposite to the bracts, not parallel, as is usual in the genus; pericarp very thin. Seed red-brown.—A. Billardieri *Hook. f. Fl. Nov. Zel.* i (1853) 215; *Fl. Tasm.* i (1860) 315, t. 95; *Handb. N.Z. Fl.* (1864) 232; *Benth. Fl. Austral.* v (1870) 180; *Cheesem Man. N.Z. Fl.* (1906) 584. Theleophyton Billardieri *Moq. in DC Prodr.* xiii, ii (1849) 115.

North Island: On sandy beaches, rare and local. Auckland—North Cape, *Buchanan!* Rangaunu Harbour, *H. Carse!* Takou Bay, *T. F. C.;* Whangaruru, *Colenso;* Great Barrier Island, Omaha, *T. Kirk!* between Tauranga and Maketu, *Spencer!* Matakana Island, *T. F. C.;* Anaura Bay (East Cape), *Bishop Williams!* Stewart Island: Paterson's Inlet, *Petrie! T. Kirk!* Chatham Islands: *Buchanan.* December–April.

A very remarkable species, differing from all others in the fruit being placed transversely to the bracts, not parallel. It is also found in Victoria and Tasmania.

4. **SALICORNIA** Linn. 1737.

Annual or perennial herbs, often woody at the base. Stems cylindric, jointed, erect or procumbent, usually much branched; branches opposite. Leaves succulent, opposite and decussate, the opposite pairs connate by their margins, thus forming joints or segments, each joint concave at the top and expanded into a kind of rim, the joint above sitting in the concavity thus formed. Inflorescence of terminal spikes. Flowers usually 3–5 together in the axils of the leaves or bracts, but the number varies from 3–12 or more in the New Zealand species. Perianth thin and membranous, 2–5-partite. Stamens 1–2. Styles 2. Utricle with a thick or thin testa, often covered with fine curved hairs.

A genus of about 25 species, abundant on salt marshes in most parts of the world. The single New Zealand species belongs to the subgenus *Arthrocnemum* Moquin, which is separated from *Salicornia* proper mainly by somewhat obscure embryological characters.

Until quite recently, *Salicornia* has been described as "leafless," and the green or reddish "joints" or "segments" were regarded as part of the succulent cortex. Thanks, however, to the researches of Douval-Jouve, it is now recognized that the "segments" are in reality fleshy internodes or leaf-bases, which carry on the assimilatory work of the plant. For information on this interesting point, reference should be made to Miss Ethel De Fraine's memoir on "The Anatomy of the Genus *Salicornia*" (Journ. Linn. Soc. Bot. xli (1913) 317); to Dr. Moss's paper "On Some Species of *Salicornia*" (Journ. Bot. xlix (1911) 177); and the Cambridge British Flora, vol. ii, p. 187 *et seq.*

1. **S. australis** *Soland. ex Forst. f. Prodr.* (1786) 88. 489.—Stems procumbent or almost prostrate below, sometimes woody at the base, usually 6–12 in. long, more rarely reaching 12–20 in.; branches numerous, jointed, ascending or erect. Joints $\frac{1}{4}$–$\frac{3}{4}$ in. long, $\frac{1}{8}$–$\frac{1}{4}$ in. diam., terete below, usually faintly compressed above, shortly 2-lobed at the tip, with a narrow thin and membranous margin. Flowering branches or spikes shorter and thicker than the ordinary branches, the joints much shorter, often broader than long. Flowers hermaphrodite or polygamous, sunk in the axils of the shortened leaf-bases (joints), usually from 5–10 in each axil, rarely as

many as 15, forming a more or less complete ring round the branch. Perianth very thick and fleshy, broad and flat and almost quadrangular at the top, narrower at the immersed base; mouth almost closed. Stamens 1 or 2. Utricle obliquely ovoid. Testa brown, coriaceous, covered with hooked hairs.—*Benth. Fl. Austral.* v (1870) 205; *Cheesem. Man. N.Z. Fl.* (1906) 585. S. indica *R. Br. Prodr.* (1810) 411 (*not of Willd.*); *A. Rich. Fl. Nouv. Zel.* (1832) 182; *A. Cunn. Precur.* (1838) n. 366; *Raoul Choix* (1846) 43; *Hook. f. Fl. Nov. Zel.* i (1853) 216; *Handb. N.Z. Fl.* (1864) 233.

North and South Islands, Chatham Islands: Abundant along the coast in salt marshes and saline places generally. Flowers through the summer and autumn.

5. **SUAEDA** Forsk. 1775.

Glabrous herbs or undershrubs. Leaves alternate, fleshy, thick or terete, entire. Flowers minute, sessile or nearly so, axillary, solitary or clustered, usually hermaphrodite; bracts and bracteoles minute, scarious. Perianth short, fleshy, 5-lobed or -partite; lobes or segments equal or unequal, without appendages or more or less carinate or crested or slightly winged, enclosing the fruit. Stamens 5, short. Styles 2–5, short, subulate, recurved. Utricle included in the perianth, membranous or spongy; pericarp thin, usually free from the seed. Seed horizontal, vertical or oblique; testa crustaceous or coriaceous; albumen wanting or scanty; embryo flat, spirally rolled.

A widely distributed genus of about 40 species, usually found on seashores or in saline places. The single species found in New Zealand has a wide range in most temperate and tropical countries.

1. **S. maritima** *Dum. Fl. Belg.* (1827) 22.—A much-branched glabrous erect or diffuse herb, varying in height from a few inches to nearly 2 ft.; stem often hard and almost woody at the base. Leaves sessile, $\frac{1}{4}$–$\frac{1}{2}$ in. long or more, linear, semi-terete or almost cylindric, acute or obtuse, thick and succulent. Flowers small, greenish, solitary or 2–4 together in the axils of the leaves, each flower usually with 1 bract and 2 bracteoles. Fruiting-perianth depressed, about $\frac{1}{12}$ in. diam., 5-lobed; lobes ovate-rounded, appressed to the utricle. Utricle membranous. Seed horizontal or very rarely vertical, dark red-brown, shining.—*Raoul Choix* (1846) 43; *Hook. f. Fl. Nov. Zel.* i (1853) 214; *Handb. N.Z. Fl.* (1864) 231; *Benth. Fl. Austral.* v (1870) 206; *Cheesem. Man. N.Z. Fl.* (1906) 586. Chenopodium maritimum *Linn. Sp. Plant.* (1753) 221; *A. Rich. Fl. Nouv. Zel.* (1832) 181; *A. Cunn. Precur.* (1838) n. 364. Salsola fruticosa *Forst. f. Prodr.* (1786) n. 131 (*not of Linn.*).

North and South Islands: Not uncommon in salt marshes from the North Cape to Foveaux Strait. December–March.

The Australian and New Zealand plant is sometimes separated from the northern form under the name of *S. australis* Moq., on account of its more suffrutescent habit, but it is very variable in this respect. Chen. Eng. 1846–72.

6. **SALSOLA** Linn. 1735.

Herbs or shrubs; branches not jointed. Leaves alternate, sessile, narrow-linear or terete, often pungent. Flowers small, solitary or fascicled, axillary, hermaphrodite, 2-bracteolate. Perianth 4–5-partite; segments

concave, thickened down the back, enlarged in fruit and furnished with a horizontal wing or protuberance, completely enclosing the utricle. Stamens 5, rarely fewer. Styles 2–3, subulate, erect or recurved. Utricle ovoid or orbicular; pericarp fleshy or membranous, not adherent to the seed. Seed usually horizontal, orbicular; testa membranous; albumen wanting; embryo spirally coiled.

Species estimated at about 40, widely spread in saline localities, but mainly in temperate regions.

1. **S. Kali** *Linn. Sp. Plant.* (1753) 222.—A rigid procumbent or diffusely branched herb 6–18 in. high; stem stout, grooved and angled, scabrid-pubescent or almost glabrous; branches spreading, often striped. Leaves spreading and recurved, variable in size, ¼–1 in. long or more, ovate-subulate with a rigid pungent point, sheathing at the base, thick and fleshy, semi-terete; the uppermost shorter and broader, almost triangular. Flowers solitary and sessile in the axils of the leaves, sometimes appearing clustered from the reduction of axillary flowering branches, each flower with 2 opposite bracteoles; floral leaves and bracteoles all pungent. Fruiting-perianth about ¼ in. diam., shorter than the bracteoles, 5-partite; segments rigid and cartilaginous at the base, furnished above with 5 broad spreading scarious wings.—*Benth. Fl. Austral.* v (1870) 207; *Cheesem. Man. N.Z. Fl.* (1906) 587. S. australis *R. Br. Prodr.* (1810) 411; *Hook. f. Fl. Nov. Zel.* i (1853) 216; *Handb. N.Z. Fl.* (1864) 232.

North and South Islands: Not uncommon on sandy shores from the North Cape southwards, but probably introduced. December–March.

A widely dispersed plant in most temperate and tropical regions, but of very doubtful nativity in New Zealand. It is a true native of Australia, however, having been gathered by Banks and Solander during Cook's first voyage.

Family XXXV. AMARANTACEAE.

Herbs, rarely shrubs. Leaves opposite or alternate, simple and entire, exstipulate. Flowers hermaphrodite or unisexual, usually regular, generally arranged in spikes or cymes or clusters, each flower seated within 2 scarious bracteoles and subtended by a larger scarious bract. Perianth inferior, persistent, rigid and scarious, often coloured, of 4–5 free or slightly connate segments, imbricate in bud. Stamens hypogynous, 4–5, seldom fewer, opposite to the sepals; filaments free or connate, or united with intervening staminodia into a cup-shaped ring; anthers 1- or 2-celled. Ovary superior, 1-celled; style long or short, simple or divided into 2–3 branches or separate styles; ovules 1 or more, attached to a slender basal funicle. Fruit usually a membranous utricle, rarely a capsule or berry, enclosed or resting upon the persistent perianth. Seeds 1 or more, usually compressed, vertical; albumen farinaceous; embryo annular or curved.

A moderate family, comprising 48 genera and nearly 500 species, most plentiful in tropical or warm countries, absent in cold climates or on the tops of high mountains. Some species of *Amarantus* and *Celosia* (cockscomb) are often cultivated in gardens, but as a whole the order is composed of weedy unattractive plants possessing no useful properties. The only New Zealand genus is found in all warm countries.

ALTERNANTHERA Forsk. 1775.

Annual or perennial herbs, usually prostrate or decumbent, rarely erect, glabrous or more or less pubescent or tomentose. Leaves opposite. Flowers small, whitish, capitate; heads sessile in the axils of the leaves, often clustered. Perianth 5-partite; segments unequal, the anterior and 2 posterior flattened, the 2 lateral innermost, concave. Stamens 2–5; filaments short, connate at the base into a membranous cup, with or without intervening staminodia; anthers 1-celled. Ovary orbicular or obovoid; style short or almost wanting; stigma capitellate or rarely 2-fid; ovule solitary, pendulous from an elongated basal funicle. Utricle compressed, ovoid or orbicular or obcordate; margins often thickened or winged. Seed vertical,

, most abundant
ntries.

ate or decum-
ng and rooting,
with 2 opposite
r-lanceolate to
d to the base,
axils. Flowers

aggregated in dense axillary clusters $\frac{1}{4}$–$\frac{1}{3}$ in. diam., minute, whitish, about $\frac{1}{12}$ in. long. Perianth-segments glabrous, rigid, acute. Stamens 2–3. Utricle broadly obcordate, with broad corky wings.—*A. Cunn. Precur.* (1838) n. 367; *Raoul Choix* (1846) 43; *Benth. Fl. Austral.* v (1870) 249; *Moq. DC. Prodr.* xiii, ii (1849) 356. A. sessilis *R. Br. Prodr.* (1810) 417; *Hook. f. Fl. Nov. Zel.* i (1853) 212; *Handb. N.Z. Fl.* (1864) 234; *Cheesem. Man. N.Z. Fl.* (1906) 577.

North Island: Marshy places from the North Cape southwards to Rotorua and Hawke's Bay, rare and local to the south of Auckland. Sea-level to 1000 ft.

This was referred by Hooker to the widely distributed *A. sessilis* R. Br.; but later writers usually place it under *A. denticulata*, which is an abundant Australian plant.

Family XXXVI. **NYCTAGINACEAE.**

Herbs or shrubs or trees. Leaves opposite or less frequently alternate, simple, entire, exstipulate. Flowers hermaphrodite or unisexual, often involucrate, usually arranged in cymose panicles. Perianth inferior, petaloid, monophyllous; tube persistent and enveloping the fruit; limb with 3–5-plicate lobes. Stamens variable in number (1–30), usually 6–10, hypogynous; filaments often unequal, inflexed in bud; anthers didymous. Ovary superior, 1-celled; style simple, terminal; stigma small, entire or multifid; ovule solitary, basilar, erect. Fruit a utricle with a membranous pericarp, firmly enclosed in the thickened or hardened base of the perianth-tube, which falls off with it. Seed erect, with a thin adherent testa; albumen farinaceous or fleshy; embryo with foliaceous cotyledons usually wrapped round the albumen, radicle inferior.

A small family, of no economical importance, with the exception of 2 or 3 wide-ranging genera almost wholly confined to tropical America. Genera 23; species about 200. The single New Zealand genus is distributed over the shores of most tropical countries.

concave, thickened down the back, enlarged in fruit and furnished with a horizontal wing or protuberance, completely enclosing the utricle. Stamens 5, rarely fewer. Styles 2–3, subulate, erect or recurved. Utricle ovoid or orbicular; pericarp fleshy or membranous, not adherent to the seed. Seed usually horizontal, orbicular; testa membranous; albumen wanting; embryo spirally coiled.

Species estimated at about 40, widely spread in saline localities, but mainly in temperate regions.

A moderate family, comprising 48 genera and nearly 500 species, most plentiful in tropical or warm countries, absent in cold climates or on the tops of high mountains. Some species of *Amarantus* and *Celosia* (cockscomb) are often cultivated in gardens, but as a whole the order is composed of weedy unattractive plants possessing no useful properties. The only New Zealand genus is found in all warm countries.

ALTERNANTHERA Forsk. 1775.

Annual or perennial herbs, usually prostrate or decumbent, rarely erect, glabrous or more or less pubescent or tomentose. Leaves opposite. Flowers small, whitish, capitate; heads sessile in the axils of the leaves, often clustered. Perianth 5-partite; segments unequal, the anterior and 2 posterior flattened, the 2 lateral innermost, concave. Stamens 2–5; filaments short, connate at the base into a membranous cup, with or without intervening staminodia; anthers 1-celled. Ovary orbicular or obovoid; style short or almost wanting; stigma capitellate or rarely 2-fid; ovule solitary, pendulous from an elongated basal funicle. Utricle compressed, ovoid or orbicular or obcordate; margins often thickened or winged. Seed vertical, lenticular; testa coriaceous.

A small genus of 16 or 18 species, mainly tropical or subtropical, most abundant in America. The New Zealand species is a common weed in warm countries.

1. **A. denticulata** *R. Br. Prodr.* (1810) 417.—A prostrate or decumbent herb. Stems numerous from the root, branched, creeping and rooting, sometimes ascending at the tips, 4–18 in. long., glabrous or with 2 opposite pubescent lines. Leaves variable in size, $\frac{1}{2}$–3 in. long, linear-lanceolate to linear-oblong or oblong-obovate, obtuse or acute, narrowed to the base, entire or obscurely denticulate, glabrous or pubescent in the axils. Flowers aggregated in dense axillary clusters $\frac{1}{4}$–$\frac{1}{3}$ in. diam., minute, whitish, about $\frac{1}{12}$ in. long. Perianth-segments glabrous, rigid, acute. Stamens 2–3. Utricle broadly obcordate, with broad corky wings.—*A. Cunn. Precur.* (1838) n. 367; *Raoul Choix* (1846) 43; *Benth. Fl. Austral.* v (1870) 249; *Moq. DC. Prodr.* xiii, ii (1849) 356. A. sessilis *R. Br. Prodr.* (1810) 417; *Hook. f. Fl. Nov. Zel.* i (1853) 212; *Handb. N.Z. Fl.* (1864) 234; *Cheesem. Man. N.Z. Fl.* (1906) 577.

North Island: Marshy places from the North Cape southwards to Rotorua and Hawke's Bay, rare and local to the south of Auckland. Sea-level to 1000 ft.

This was referred by Hooker to the widely distributed *A. sessilis* R. Br.; but later writers usually place it under *A. denticulata*, which is an abundant Australian plant.

Family XXXVI. NYCTAGINACEAE.

Herbs or shrubs or trees. Leaves opposite or less frequently alternate, simple, entire, exstipulate. Flowers hermaphrodite or unisexual, often involucrate, usually arranged in cymose panicles. Perianth inferior, petaloid, monophyllous; tube persistent and enveloping the fruit; limb with 3–5-plicate lobes. Stamens variable in number (1–30), usually 6–10, hypogynous; filaments often unequal, inflexed in bud; anthers didymous. Ovary superior, 1-celled; style simple, terminal; stigma small, entire or multifid; ovule solitary, basilar, erect. Fruit a utricle with a membranous pericarp, firmly enclosed in the thickened or hardened base of the perianth-tube, which falls off with it. Seed erect, with a thin adherent testa; albumen farinaceous or fleshy; embryo with foliaceous cotyledons usually wrapped round the albumen, radicle inferior.

A small family, of no economical importance, with the exception of 2 or 3 wide-ranging genera almost wholly confined to tropical America. Genera 23; species about 200. The single New Zealand genus is distributed over the shores of most tropical countries.

PISONIA Linn.

Trees or shrubs, usually unarmed, rarely spinous. Leaves opposite or scattered. Flowers unisexual or hermaphrodite, small, 2–3-bracteolate at the base, usually arranged in lax or dense cymose panicles. Perianth of the male flowers funnel-shaped or almost campanulate, of the females tubular, sometimes swollen at the base; limb 5-toothed; teeth short, induplicate-valvate, erect or patent. Stamens 6–10; filaments unequal, connate at the base into a tube or ring; anthers oblong or didymous, exserted or included. Ovary elongated, narrowed into a slender included or exserted style; stigma obliquely capitate or dilated, often fimbriate. Fruiting-perianth elongated or oblong, 5-ribbed or cylindrical, smooth or glandular-muricate, usually viscid, firmly enclosing the membranous utricle. Seed solitary, oblong, longitudinally grooved; embryo straight, the cotyledons convolute, enclosing the scanty albumen.

A large genus in tropical and subtropical America, with a few species in southern Asia, Australia, Polynesia, and the Mascarene Islands. The New Zealand species occurs in Norfolk Island and Australia, and may possibly have a wider range.

1. **P. Brunoniana** *Endl. Prodr. Fl. Norfl.* (1833) 43.—A glabrous shrub or small tree, usually 12–20 ft. high, but sometimes attaining 35 ft. with a trunk 2 ft. in diam.; wood soft, brittle. Leaves usually opposite, but often irregularly alternate or sometimes approximate in threes, petiolate, 4–15 in. long, oblong to ovate-oblong or elliptic-oblong, obtuse or subacute, quite entire, membranous and flaccid when young, but becoming firm in age. Cymes much branched, terminal, many-flowered. Flowers usually hermaphrodite, but sometimes the stamens are abortive. Perianth $\frac{1}{5}$ in. long, greenish, glabrous or puberulous, funnel-shaped with a campanulate mouth. Stamens 6–8; anthers equalling the perianth or slightly exserted. Fruit 1–$1\frac{1}{4}$ in. long, linear, narrowed above, 5-ribbed; ribs minutely papillose, extremely viscid.—*Hook. f. Handb. N.Z. Fl.* (1864) 229; *Benth. Fl. Austral.* v (1870) 280; *T. Kirk Forest Fl.* (1889) t. 140; *Cheesem. Man. N.Z. Fl.* (1906) 574. P. Sinclairii *Hook. f. Fl. Nov. Zel.* i (1853) 209, t. 50. P. Mooreiana *F. Muell. Fragm.* i (1858) 20.

Kermadec Islands: Not uncommon, *T. F. C., W. R. B. Oliver!* North Island: Three Kings Islands, *T. F. C.;* Whangape Harbour, *Berggren, McLennan!* between Whangarei and Ngunguru, *Colenso!* Hen and Chickens Islands, *T. Kirk! T. F. C.;* Cape Bream Tail, *R. Hastie;* Great Barrier Island, Arid Island, *T. Kirk!* Little Barrier Island, Cuvier Island, *T. F. C.;* Cabbage Bay, *Adams!* East Cape, *Bishop Williams!* Sea-level to 500 ft. *Parapara.* Flowers most of the year.

Also found in Norfolk Island, Lord Howe Island, New South Wales, and Queensland. The fruits are so excessively viscid that small birds, such as the white-eye (*Zosterops*) and fantail (*Rhipidura*), are often caught and glued down by the feathers, and fail to free themselves.

Family XXXVII. AIZOACEAE.

Annual or perennial herbs, rarely undershrubs, of very various habit. Leaves opposite or alternate or whorled, simple, often fleshy, stipules wanting or scarious. Flowers regular, usually hermaphrodite, solitary or fascicled or cymose. Calyx free or adnate to the ovary, 4–5 celled or -partite, imbricate. Petals either narrow and numerous, or 4–5 and small, or altogether wanting. Stamens perigynous or rarely hypogynous, few or many; filaments free or connate at the base. Ovary superior or

Heimerliodendron nov. nom.

In 1936 I established the new genus Heimerlia, based on Ceodes Brunoniana (Endl.) Skottsb. (Calpidia Brunoniana (Endl.) Heimerl: Sv. bot. tidskr. 30, p.738). The genus was named in honour of Dr. Anton Heimerl, well-known authority on the Nyctaginiaceae, with his kind permission. Unfortunately Dr. Heimerl, when he gave his consent, had forgotten that there already was a plant genus Heimerlia [illegible] o the Mycetozoa an[illegible] i professoris [illegible].s" (Heimerlia hyalina v. Höhn. Mycologici 1, 1903, p.391). Consequently, I had no reason to search the literature for a name Heimerlia. Some time ago I accidentally came across the name in A. & G. Lister's Monograph of the Mycetozoa (2nd ed., 1911, p.170), where H. hyalina is supposed not to belong to the Mycetozoa at all and suspected to be identical with another doubtful fungus, Endodromia vitrea Berk. 1841. In any case Heimerlia Skottsb. is a later homonym and has to be renamed. I call it Heimerliodendron, with the new combination H. Brunonianum (Endl.) Skottsb.

I shall use this occasion to correct a misprint in my paper referred to above: on p.738, last line, the signs o and ♀ have to change place.

PISONIA Linn.

Trees or shrubs, usually unarmed, rarely spinous. Leaves opposite or scattered. Flowers unisexual or hermaphrodite, small, 2–3-bracteolate at the base, usually arranged in lax or dense cymose panicles. Perianth of the male flowers funnel-shaped or almost campanulate, of the females tubular, sometimes swollen at the base; limb 5-toothed; teeth short, induplicate-valvate, erect or patent. Stamens 6–10; filaments unequal, connate at the base into a tube or ring; anthers oblong or didymous, exserted or included. Ovary elongated, narrowed into a slender included or exserted style; stigma obliquely capitate or dilated, often fimbriate. Fruiting-perianth elongated or oblong, 5-ribbed or cylindrical, smooth or glandular-muricate, usually viscid, firmly enclosing the membranous utricle. Seed solitary, oblong, longitudinally grooved; embryo straight, the cotyledons convolute, enclosing the scanty albumen.

Asia, Australia, Polynesia, and the Masc
in Norfolk Island and Australia, and ma

Pisonia Brunoniana = Heimerlia Brunoniana

1. **P. Brunoniana** *Endl. Prodr.* [illegible] 10.—A glabrous shrub or small tree, usually 12–20 ft. high, but sometimes attaining 35 ft. with a trunk 2 ft. in diam.; wood soft, brittle. Leaves usually opposite, but often irregularly alternate or sometimes approximate in threes, petiolate, 4–15 in. long, oblong to ovate-oblong or elliptic-oblong, obtuse or subacute, quite entire, membranous and flaccid when young, but becoming firm in age. Cymes much branched, terminal, many-flowered. Flowers usually hermaphrodite, but sometimes the stamens are abortive. Perianth $\frac{1}{5}$ in. long, greenish, glabrous or puberulous, funnel-shaped with a campanulate mouth. Stamens 6–8; anthers equalling the perianth or slightly exserted. Fruit 1–$1\frac{1}{4}$ in. long, linear, narrowed above, 5-ribbed; ribs minutely papillose, extremely viscid.—*Hook. f. Handb. N.Z. Fl.* (1864) 229; *Benth. Fl. Austral.* v (1870) 280; *T. inferior, 2–5-celled; styles as many as the cells, free or united at the base; ovules either solitary in the cells and basal, or numerous and axile. Fruit generally a capsule with loculicidal or transverse dehiscence, more rarely drupaceous or separating into 1-seeded cocci. Seeds solitary or many, usually compressed; albumen scanty or copious; embryo slender, curved round the albumen, terete.

A large family, comprising 22 genera and nearly 500 species, mostly tropical or subtropical, and especially plentiful in South Africa; rare or absent in cold climates. The properties of the family are unimportant. Many species of *Mesembryanthemum* have showy flowers, and are cultivated in gardens; and *Tetragonia* is occasionally used as a pot herb. The remaining genera are mostly insignificant weeds. Both the New Zealand genera are widely distributed, although much more numerously represented in South Africa than elsewhere.

1. **MESEMBRYANTHEMUM** Linn.

More or less succulent herbs or undershrubs. Leaves usually opposite, thick and fleshy, trigonous or terete or flat. Flowers conspicuous, terminating the branches or axillary. Calyx-tube adnate with the ovary; lobes 5. Petals numerous, linear, in one or several rows. Stamens numerous, in many rows. Ovary inferior, with 5 or more cells, rarely 4-celled; styles as many as the cells, free or connate at the base, stigmatic on the inner side; ovules very numerous. Capsule enclosed in the persistent calyx, depressed at the apex and loculicidally dehiscent, the valves opening in a star-like manner. Seeds numerous, minute; testa crustaceous.

An enormous South African genus, containing fully 350 species; rare elsewhere, although a few species are widely scattered along the shores of many parts of the world.

Leaves less than 1 in. long. Flowers ¾–1 in. diam.; peduncles usually short .. .. 1. *M. australe.*
Leaves more than 1 in. long. Flowers 1½ in. diam., on long peduncles .. .. 2. *M. aequilaterale.*

Disphyma australe (G. Forst.) N.E.

1. **M. australe** *Sol. ex Forst. f. Prodr.* (1786) n. 523.—Stems 1–4 ft. long, prostrate and rooting at the nodes, woody, terete. Leaves opposite or in opposite fascicles, connate at the base, ½–1¼ in. long, linear or linear-oblong, triquetrous, flat above, convex and keeled beneath, acute or obtuse, thick and fleshy, often glaucous. Flowers ¾–1 in. diam., white or pink; peduncles usually shorter than the leaves, but sometimes nearly twice their length. Calyx-tube fleshy, obconic; lobes 5, 2 of them much longer than the others. Petals very numerous, spreading. Styles 5–8. Capsule 5–8-celled. — *A. Cunn. Precur.* (1839) n. 522; *Raoul Choix* (1846) 48; *Hook. f. Fl. Nov. Zel.* i (1853) 76; *Handb. N.Z. Fl.* (1864) 83; *Benth. Fl. Austral.* iii (1866) 324; *T. Kirk Students' Fl.* (1899) 184; *Cheesem. Man. N.Z. Fl.* (1906) 191.

Kermadec Islands, North and South Islands, Chatham Islands, Stewart Island: Common everywhere on rocky coasts. *Horokaka; New Zealand Ice-plant.* October–March. Also abundant in Australia and Tasmania, Norfolk Island, and Lord Howe Island.

1794?

2. **M. aequilaterale** *Haw. Misc. Nat.* (1803) 77.—Stems robust, woody at the base, prostrate or ascending, sometimes several feet in length; flowering branches short, suberect. Leaves opposite, stem-clasping, 1–3 in.

= Carpobrotus aequilaterum (Haw.) N.E. Br. J. Bot. 66: 324 (1928).
= " aequilateralis (Haw.) Black. Trans. R. Soc. Austr. 56 (1932) 39.

long, very fleshy, linear, acutely triquetrous, smooth, equal-sided or laterally compressed. Flowers 1½ in. diam.; peduncles 1–3 in. long, thickened upwards, winged. Calyx-tube turbinate, ½ in. long or more; lobes unequal, the 2 larger ones often as long as the tube. Petals spreading. Styles 6–10. Capsule 6–10-celled.—*DC. Prodr.* iii (1828) 429; *Benth. Fl. Austral.* iii (1866) 324; *T. Kirk Students' Fl.* (1899) 184; *Cheesem. Man. N.Z. Fl.* (1906) 191.

North Island: Coast near Napier; Castle Point, *T. Kirk!* December–February. A common plant in Australia and Tasmania, also found in California and Chile. I have seen no indigenous specimens.

2. **TETRAGONIA** Linn.

Herbs or undershrubs. Stems trailing or erect. Leaves alternate, petiolate, flat but more or less succulent. Flowers axillary, solitary or few together. Calyx-tube adnate to the ovary and often produced above it, terete or angled; lobes 3–5. Petals wanting. Stamens inserted on the calyx-tube, variable in number, solitary or few or many. Ovary inferior, 2–8-celled; styles as many as the cells; ovules solitary in each cell, pendulous. Fruit indehiscent, globose or obconic, often horned or tuberculate; endocarp hard or almost bony; epicarp coriaceous or fleshy.

A small genus of about 25 species, most of which are natives of South Africa, a few only being scattered over the coasts of America, Australasia, and parts of Asia.

Leaves 1–4 in. Fruit turbinate, hard, angular, horned above .. 1. *T. expansa.*

Leaves ¾–2 in. Fruit globose, succulent, not horned .. .. 2. *T. trigyna.*

1. **T. expansa** *Murr. in Comm. Gotting.* vi (1783) 13.—A more or less succulent minutely papillose herb. Stems 1–2 ft. high, decumbent or suberect, glabrous or sparingly puberulous. Leaves 1–4 in. long, ovate-rhomboid or triangular, obtuse or subacute, suddenly narrowed into the petiole, quite entire or very obscurely sinuate. Flowers small, yellowish, solitary or rarely 2 together, sessile or on very short peduncles. Calyx-tube broadly turbinate; lobes about as long as the tube, broad, obtuse. Stamens 12–20, irregularly inserted. Ovary 3–8-celled; styles the same number. Fruit about ⅓ in. long, hard and dry, almost turbinate, angular, usually furnished at the summit with 2–4 prominent teeth or horns.—*A. Rich. Fl. Nouv. Zel.* (1832) 320; *A. Cunn. Precur.* (1839) n. 523; *Raoul Choix* (1846) 48; *Hook. f. Fl. Nov. Zel.* i (1853) 77; *Handb. N.Z. Fl.* (1864) 84; *Benth. Fl. Austral.* iii (1866) 325; *T. Kirk Students' Fl.* (1899) 185; *Cheesem. Man. N.Z. Fl.* (1906) 192. T. halimifolia *Forst. f. Prodr.* (1786) n. 223.

Kermadec Islands, North and South Islands, Stewart Island: Not uncommon along the coasts; seldom found inland. *Kokihi.* November–February.

This has long been cultivated in Europe as an edible plant, under the name of "New Zealand spinach." It is also a native of Australia and Tasmania, Norfolk Island and Lord Howe Island, Japan, and extra-tropical South America.

2. **T. trigyna** *Banks and Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 77.—Stems 1–8 ft. long, branched, trailing or frequently climbing, terete, woody at the base. Leaves ¾–2 in. long, broadly ovate-rhomboid or rounded-ovate, obtuse, abruptly narrowed into the petiole, fleshy, usually covered with transparent papillae. Flowers small, yellowish, solitary or rarely

2 together; peduncles about as long as the flower. Ovary 2- rarely 3-celled; styles the same number as the cells. Fruit ¼ in. diam., subglobose, succulent, bright-red, obscurely lobed or quite even, not horned. Seeds 1–3.—*Hook. f. Handb. N.Z. Fl.* (1864) 84; *T. Kirk Students' Fl.* (1899) 185; *Cheesem. Man. N.Z. Fl.* (1906) 192. T. implexicoma *Hook. f. var.* chathamica *F. Muell. Veg. Chath. Is.* (1864) 12.

Kermadec Islands, North and South Islands, Stewart Island, Chatham Islands: In many places on the shores, but often local. November–February.

Easily distinguished from *T. expansa* by the trailing and often climbing habit, smaller broader leaves, and bright-red fleshy fruit. The flowers of both this species and *T. expansa* are frequently unisexual. It is very closely allied to the Australian and Tasmanian *T. implexicoma* Hook. f., but is said to differ in the broader leaves, broader and more unequal calyx-lobes, styles 3–4, and the fruit 3–4-celled.

Family XXXVIII. **PORTULACACEAE.**

Herbs, usually fleshy and glabrous, occasionally clothed with long hairs. Leaves opposite or rarely alternate, entire, generally exstipulate. Flowers regular, hermaphrodite. Sepals 2, rarely more, imbricate. Petals 4–5, hypogynous or rarely perigynous, free or united below. Stamens either equal in number to the petals and opposite to them or indefinite, often adnate to the base of the petals. Ovary free or rarely half-inferior, 1-celled; style 3–8-fid; ovules few or many, affixed to a free central or basal placenta. Fruit a capsule, either dehiscing with as many valves as style-branches, or opening by a transverse lid. Seeds 1 to many; embryo curved round a farinaceous albumen.

A small family, having its headquarters in America; found more sparingly in South Africa and Australia; decidedly rare in Asia, north Africa, and Europe. Genera 16; species about 225. Some of the American genera are shrubby; and the widely distributed *Portulaca* (naturalized in New Zealand) differs from the rest of the **family** in having perigynous petals and stamens, and a half-inferior ovary. Of the New Zealand genera, *Claytonia* is mainly American, and *Montia* occurs in the temperate regions of both hemispheres. I have followed Professor Ewart in transferring *Hectorella* to the *Caryophyllaceae*.

Stems slender. Stamens 5, opposite the petals. Capsule 3–many-seeded, seeds shining .. .. 1. Claytonia.
Stems slender. Stamens usually 3, opposite the petals. Capsule 1–3-seeded, seeds dull and opaque .. .. 2. Montia.

1. **CLAYTONIA** Linn.

Annual or perennial low-growing glabrous and succulent herbs. Radical leaves petiolate, cauline opposite or alternate. Flowers solitary or in terminal or axillary racemes or cymes. Sepals 2, persistent. Petals 5, hypogynous. Stamens 5, adhering to the petals at the base. Ovary free; ovules few; style 3-cleft. Capsule globose or ovoid, membranous, 3-valved. Seeds reniform or orbicular, flattened.

Species about 20, all from North America or north-eastern Asia with the exception of the following one, which is confined to Australia and New Zealand.

1. **C. australasica** *Hook. f.* in *Hook. Ic. Plant.* (1840) t. 293.—A perfectly glabrous tender and succulent usually matted plant, with slender creeping stems 1–6 in. long. Leaves very variable in size, ¼–1½ in. long, alternate

or in distant pairs, narrow-linear or linear-spathulate, obtuse, dilated into broad membranous sheaths at the base. Flowers large, $\frac{1}{4}$–$\frac{1}{2}$ in. diam., white or rose, terminal or leaf-opposed, solitary or in few-flowered lax racemes; pedicels long, slender. Sepals small, broadly orbicular. Petals much longer, broad-obovate. Capsule globose, mucronate, usually slightly exceeding the sepals. Seeds generally 3, black, smooth and shining.—*Fl. Nov. Zel.* i (1853) 73; *Handb. N.Z. Fl.* (1864) 26; *Benth. Fl. Austral.* i (1863) 177; *T. Kirk Students' Fl.* (1899) 65; *Cheesem. Man. N.Z. Fl.* (1906) 71.

North Island: Common on the high mountains of the interior; from Mount Egmont and Ruapehu southwards, ascending to over 6500 ft., *T. F. C.* and many others. South Island, Stewart Island: Common in mountain districts throughout, descending to sea-level in Otago and Stewart Island. An abundant plant in the mountains of south-eastern Australia and Tasmania.

A variable plant. When growing in dry or exposed places it is often very small and densely tufted; but in watery situations the stems lengthen out considerably and the leaves become longer. Mr. Buchanan (Trans. N.Z. Inst. iii (1871) 210) has described two varieties characterized by the peduncles in one being 2-flowered, and in the other racemose; but I find the number of flowers to be very inconstant.

2. **MONTIA** Linn.

A small glabrous herb. Leaves opposite, slightly fleshy. Flowers small, axillary or shortly racemose. Sepals 2, ovate, persistent. Petals 5, united at the base into a 5-lobed corolla, split open on one side. Stamens 3, rarely 5, inserted on the petals. Ovary free; ovules 3. Capsule globose, 3-valved, 3-seeded. Seeds nearly orbicular.

A monotypic genus, widely distributed in the North and South Temperate Zones.

1. **M. fontana** *Linn. Sp. Plant.* (1753) 87.—A slender perfectly glabrous branching herb, forming dense tufts 1–5 in. high, sometimes longer and weaker when growing in water. Leaves opposite, $\frac{1}{4}$–1 in. long, linear-lanceolate or spathulate, acute or subacute, quite entire. Flowers minute, solitary or in 2–3-flowered racemes, drooping. Petals slightly longer than the sepals. Capsules small.—*Hook. f. Fl. Antarct.* i (1844) 13; *Fl. Nov. Zel.* i (1853) 74; *Handb. N.Z. Fl.* (1864) 27; *T. Kirk Students' Fl.* (1899) 65; *Cheesem. Man. N.Z. Fl.* (1906) 72.

North and South Islands, Stewart Island, Auckland, Campbell, Antipodes, and Macquarie Islands: Abundant in watery places, from Rotorua and Taranaki southwards. Altitudinal range from sea-level to 5000 ft.

Family XXXIX. **CARYOPHYLLACEAE.**

Herbs, very rarely woody at the base; branches usually swollen at the nodes. Leaves opposite, quite entire or minutely serrulate, often united at the base; stipules scarious or wanting. Flowers regular, hermaphrodite. Sepals 4–5, free or cohering into a tubular calyx, imbricate. Petals 4–5 or occasionally absent, hypogynous or rarely perigynous, entire or lobed. Stamens 8–10, rarely fewer, inserted with the petals. Ovary free, 1-celled or imperfectly 3–5-celled at the base; styles 2–5, free or more or less connate into a single style; ovules 2 to many, attached to a free central or basal placenta. Fruit usually capsular, splitting into as

Parakeleba. Pflanzenf. 16c. 1934: 327 accept Arenaria truncata Col. as indigenous to N.Z.

many or twice as many valves as styles, very rarely indehiscent. Seeds few or many; albumen farinaceous, usually more or less surrounded by the narrow curved embryo.

A large and very natural family, found in every part of the world, but most abundant in temperate regions, particularly of the Northern Hemisphere; rare in the tropics, unless on high mountains. Genera about 55; species 1200 or more. The family contains some handsome garden-plants, as the various kinds of carnations and pinks, but as a whole the species are insignificant, possessing no important properties or uses. Of the 6 genera indigenous in New Zealand, *Hectorella* is endemic, *Colobanthus* is confined to the South Temperate Zone; the remaining 4 occur in both hemispheres. More than 20 naturalized species have become well established, all of them of northern origin.

Sepals united into a tubular calyx (Sileneae).

Calyx broadly 5-nerved. Styles 2. Capsule deeply 4-valved ..	1. GYPSOPHILA.

Sepals free (Alsineae).

Petals 2-fid. Styles 3–5. Capsule globular or ovoid, opening with as many valves as styles. No stipules	2. STELLARIA.
Petals wanting. Styles 4–5. Stamens equal in number to the sepals. No stipules	3. COLOBANTHUS.
Petals entire. Styles 3. Capsule 3-valved. Stipules scarious..	4. SPERGULARIA.
Alpine herbs with densely tufted stems. Stamens 5, alternate with the petals	5. HECTORELLA.
Densely tufted herbs. Petals wanting. Stamen usually 1 ..	6. SCLERANTHUS.

1. **GYPSOPHILA** Linn.

Annual or perennial herbs, often glaucous, sometimes glandular-pubescent or hispid. Flowers usually small, paniculate or solitary in the forks of the stem. Calyx campanulate or turbinate, 5-toothed or 5-lobed, with 5 broad green nerves separated by membranous interspaces. Petals 5, with a narrow claw; limb entire or notched. Stamens 10. Ovary 1-celled; styles 2; ovules many. Capsule globose or ovoid, 4-valved to or below the middle. Seeds subreniform, laterally attached, embryo curved round the albumen.

A genus of about 50 species, with the exception of the following one all limited to the Mediterranean region and extra-tropical Asia.

1. **G. tubulosa** *Boiss. Diagn. Fl. Or.* i (1842) 11.—A dichotomously branched erect or spreading annual 2–6 in. high, glandular-pubescent in all its parts, often viscid; stems and branches slender, terete. Leaves linear-

Nelson—Tarndale, *W. T. L. Travers.* Marlborough—*Buchanan.* Canterbury—Lake Forsyth, Lake Lyndon, *T. Kirk!* Rangitata Valley, *Sinclair* and *Haast;* Mackenzie Plains and Lake Tekapo, *T. F. C.;* Lake Ohau, *Haast.* Otago—Common in the interior, *Hector* and *Buchanan, Petrie!* Altitudinal range from sea-level to 3000 ft. November–January.

Also widely diffused in Australia, but found elsewhere only in south Europe and Asia Minor, from whence it was originally described. Several botanists have suggested

or in distant pairs, narrow-linear or linear-spathulate, obtuse, dilated into broad membranous sheaths at the base. Flowers large, $\frac{1}{4}$–$\frac{1}{2}$ in. diam., white or rose, terminal or leaf-opposed, solitary or in few-flowered lax racemes; pedicels long, slender. Sepals small, broadly orbicular. Petals much longer, broad-obovate. Capsule globose, mucronate, usually slightly exceeding the sepals. Seeds generally 3, black, smooth and shining.—*Fl. Nov. Zel.* i (1853) 73; *Handb. N.Z. Fl.* (1864) 26; *Benth. Fl. Austral.* i (1863) 177; *T. Kirk Students' Fl.* (1899) 65; *Cheesem. Man. N.Z. Fl.* (1906) 71.

North Island: Common on the high mountains of the interior; from Mount Egmont and Ruapehu southwards, ascending to over 6500 ft., *T. F. C.* and many others. South Island, Stewart Island: Common in mountain districts throughout, descending to sea-level in Otago and Stewart Island. An abundant plant in the mountains of south-eastern Australia and Tasmania.

A variable plant. When growing in dry or exposed places it is often very small and densely tufted; but in watery situations the stems lengthen out considerably and the leaves become longer. Mr. Buchanan (Trans. N.Z. Inst. iii (1871) 210) has described two varieties characterized by the peduncles in one being 2-flowered, and in the other racemose; but I find the number of flowers to be very inconstant.

2. **MONTIA** Linn.

A small glabrous herb. Leaves opposite, slightly fleshy. Flowers small, axillary or shortly racemose. Sepals 2, ovate, persistent. Petals 5, united at the base into a 5-lobed corolla, split open on one side. Stamens 3, rarely 5, inserted on the petals. Ovary free; ovules 3. Capsule globose, 3-valved, 3-seeded. Seeds nearly orbicular.

A monotypic genus, widely distributed in the North and South Temperate Zones.

1. **M. fontana** *Linn. Sp. Plant.* (1753) 87.—A slender perfectly glabrous branching herb, forming dense tufts 1–5 in. high, sometimes longer and weaker when growing in water. Leaves opposite, $\frac{1}{4}$–1 in. long, linear-lanceolate or spathulate, acute or subacute, quite entire. Flowers minute, solitary or in 2–3-flowered racemes, drooping. Petals slightly longer than the sepals. Capsules small.—*Hook. f. Fl. Antarct.* i (1844) 13; *Fl. Nov. Zel.* i (1853) 74; *Handb. N.Z. Fl.* (1864) 27; *T. Kirk Students' Fl.* (1899) 65; *Cheesem. Man. N.Z. Fl.* (1906) 72.

North and South Islands, Stewart Island, Auckland, Campbell, Antipodes, and Macquarie Islands: Abundant in watery places, from Rotorua and Taranaki southwards. A[illegible]

Herbs, the nodes united at hermaphrc

Petals 4–5 [illegible] hypogynous or rarely perigynous, entire or lobed. Stamens 8–10, rarely fewer, inserted with the petals. Ovary free, 1-celled or imperfectly 3–5-celled at the base; styles 2–5, free or more or less connate into a single style; ovules 2 to many, attached to a free central or basal placenta. Fruit usually capsular, splitting into as

Parakeleya. Bjamsey. Ilc. 1934: 327 accept Aegina truncata Col. as indigenous to N.Z.

many or twice as many valves as styles, very rarely indehiscent. Seeds few or many; albumen farinaceous, usually more or less surrounded by the narrow curved embryo.

A large and very natural family, found in every part of the world, but most abundant in temperate regions, particularly of the Northern Hemisphere; rare in the tropics, unless on high mountains. Genera about 55; species 1200 or more. The family contains some handsome garden-plants, as the various kinds of carnations and pinks, but as a whole the species are insignificant, possessing no important properties or uses. Of the 6 genera indigenous in New Zealand, *Hectorella* is endemic, *Colobanthus* is confined to the South Temperate Zone; the remaining 4 occur in both hemispheres. More than 20 naturalized species have become well established, all of them of northern origin.

Sepals united into a tubular calyx (Sileneae).

Calyx broadly 5-nerved. Styles 2. Capsule deeply 4-valved ..	1. Gypsophila.

Sepals free (Alsineae).

Petals 2-fid. Styles 3–5. Capsule globular or ovoid, opening with as many valves as styles. No stipules	2. Stellaria.
Petals wanting. Styles 4–5. Stamens equal in number to the sepals. No stipules	3. Colobanthus.
Petals entire. Styles 3. Capsule 3-valved. Stipules scarious..	4. Spergularia.
Alpine herbs with densely tufted stems. Stamens 5, alternate with the petals	5. Hectorella.
Densely tufted herbs. Petals wanting. Stamen usually 1 ..	6. Scleranthus.

1. **GYPSOPHILA** Linn.

Annual or perennial herbs, often glaucous, sometimes glandular-pubescent or hispid. Flowers usually small, paniculate or solitary in the forks of the stem. Calyx campanulate or turbinate, 5-toothed or 5-lobed, with 5 broad green nerves separated by membranous interspaces. Petals 5, with a narrow claw; limb entire or notched. Stamens 10. Ovary 1-celled; styles 2; ovules many. Capsule globose or ovoid, 4-valved to or below the middle. Seeds subreniform, laterally attached, embryo curved round the albumen.

A genus of about 50 species, with the exception of the following one all limited to the Mediterranean region and extra-tropical Asia.

1. **G. tubulosa** *Boiss. Diagn. Fl. Or.* i (1842) 11.—A dichotomously branched erect or spreading annual 2–6 in. high, glandular-pubescent in all its parts, often viscid; stems and branches slender, terete. Leaves linear-subulate, $\frac{1}{6}$–$\frac{1}{2}$ in., rarely longer. Flowers solitary in the forks of the branches, sometimes appearing axillary from one branch only being developed; peduncles slender, $\frac{1}{4}$–$\frac{1}{2}$ in. long. Calyx tubular, with 5 short teeth. Petals red or whitish-red, linear-oblong, slightly exceeding the calyx. Capsule ovoid-oblong, longer than the calyx, 5-valved at the apex. Seeds black, transversely rugose and pitted.—*Hook f. Fl. Nov. Zel.* ii (1855) 325; *Handb. N.Z. Fl.* (1864) 22; *Benth. Fl. Austral.* i (1863) 155; *T. Kirk Students' Fl.* (1899) 54; *Cheesem. Man. N.Z. Fl.* (1906) 62.

See also T. 43 (1913) 233.

North Island: East coast, from Ahuriri to Cape Palliser, *Colenso!* South Island: Nelson—Tarndale, *W. T. L. Travers.* Marlborough—*Buchanan.* Canterbury—Lake Forsyth, Lake Lyndon, *T. Kirk!* Rangitata Valley, *Sinclair* and *Haast;* Mackenzie Plains and Lake Tekapo, *T. F. C.;* Lake Ohau, *Haast.* Otago—Common in the interior, *Hector* and *Buchanan, Petrie!* Altitudinal range from sea-level to 3000 ft. November–January.

Also widely diffused in Australia, but found elsewhere only in south Europe and Asia Minor, from whence it was originally described. Several botanists have suggested

that it has been introduced both into Australia and New Zealand, but so far as the latter country is concerned no evidence has ever been obtained in support of such a view. It seems highly improbable that a plant found only in south Europe and Asia Minor should arrive in Australia at a sufficiently early date to be detected by Robert Brown before 1805, and also travel to New Zealand, and become well established, before it was gathered by Mr. Colenso shortly after his arrival in 1834. On the assumption that it is a naturalized plant, it is also difficult to account for the fact that is has not further increased its range during the last fifty years.

2. STELLARIA Linn. 1753.

Annual or perennial herbs of very various habit, usually low-growing and diffuse, glabrous or pubescent. Flowers white, solitary or cymose, terminal or lateral. Sepals 5, rarely 4. Petals the same number, 2-cleft, rarely wanting. Stamens 10 or fewer by abortion, hypogynous. Ovary 1-celled; styles 3, or rarely 2, 4, or 5; ovules few or many. Capsule globose to oblong, few or many-seeded, dehiscing to below the middle into twice as many valves as styles. Seeds granulate, tuberculate, or pitted.

A genus of nearly 100 species, dispersed over the whole world, but most abundant in cold and temperate regions. The 6 indigenous species are all endemic, but 3 others from the Northern Hemisphere have become naturalized. One of these, *S. media* Linn., the common chickweed, is now so well established and has penetrated into such remote localities (it has been gathered in Macquarie Island) that a beginner will be certain to consider it indigenous. It has flaccid procumbent much-branched stems 6 in. to 2 ft. long, marked by an alternate pubescent line; ovate-acuminate leaves, the lower on long ciliate petioles; and flowers both axillary and in terminal cymes.

Creeping and matted. Leaves orbicular. Sepals subulate-lanceolate, acute	1. *S. parviflora.*
Creeping and matted. Leaves orbicular, ovate, obovate, or lanceolate. Sepals oblong-ovate, obtuse	2. *S. decipiens.*
Small. Leaves soft, ovate. Sepals oblong, obtuse	3. *S. minuta.*
Creeping or suberect. Leaves linear-oblong. Flowers almost sessile. Sepals ovate-lanceolate, acuminate	4. *S. elatinoides.*
Glaucous, erect, dichotomously branched. Leaves linear. Flowers large, green, ¾ in.	5. *S. Roughii.*
Tufted, suberect, rigid and wiry. Leaves acerose, linear-subulate	6. *S. gracilenta.*

1. **S. parviflora** *Banks and Sol. ex Hook. f. Fl. Nov. Zel.* i (1853) 25.—A slender pale-green flaccid herb with creeping stems rooting at the nodes, often much branched and forming broad matted patches 6–12 in. diam. or more, glabrous or with a few weak hairs on the petioles. Leaves membranous, $\frac{1}{4}$–$\frac{1}{2}$ in. long, orbicular or broadly ovate, acute or mucronate, rarely cordate at the base; blade usually longer than the petiole. Peduncles solitary, axillary, usually much longer than the leaves, 1–3-flowered; a pair of bracteoles at the fork of the peduncle, and another pair on one and sometimes on all the pedicels. Flowers minute, $\frac{1}{12}$ in. diam. Sepals subulate-lanceolate or oblong-lanceolate, acute, with white scarious margins. Petals wanting or 5, 2-cleft to nearly the base, shorter than the sepals. Styles 3. Capsule longer than the sepals, deeply 6-valved. Seeds 4–12, red-brown, deeply pitted.—*Hook. f. Handb. N.Z. Fl.* (1864) 23; *T. Kirk Students' Fl.* (1899) 57; *Cheesem. Man. N.Z. Fl.* (1906) 63. S. oligosperma *Col. in Trans. N.Z. Inst.* xviii (1886) 257. S. pellucida *Col. l.c.* xxvii (1895) 383. see Kew. Bc. 1934. 322.

North and South Islands, Stewart Island, Chatham Islands: Abundant throughout in both lowland and mountain districts, ascending to over 4000 ft.

Mr. Colenso's herbarium contains numerous examples of his *S. oligosperma* and *S. pellucida*, but I can find no characters to distinguish them from the ordinary form of the species, even as varieties.

2. **S. decipiens** *Hook. f. Fl. Antarct.* i (1844) 7.—A pale-green much and loosely branched decumbent herb, forming matted patches. Leaves $\frac{1}{4}$–$\frac{2}{3}$ in. long, orbicular or orbicular-ovate or broadly obovate, rather fleshy, acute or apiculate, with a callous tip, narrowed into a broad and slightly ciliate petiole. Peduncles axillary, usually 2-flowered, generally longer than the leaves; a pair of bracts at the fork of the peduncle and another on one of the pedicels. Flowers small, rather larger than those of *S. parviflora*. Sepals 5, oblong-ovate, obtuse or subacute. Petals 5, 2-cleft to the base, shorter than the sepals, often wanting. Capsules $\frac{1}{3}$ longer than the sepals, oblong-ovoid, deeply 6-valved. Seeds dark red-brown, tuberculate.—*Ic. Plant.* (1844) t. 680; *Handb. N.Z. Fl.* (1864) 23; *T. Kirk Students' Fl.* (1899) 57; *Cheesem. Man. N.Z. Fl.* (1906) 63; *Subantarctic Is. N.Z.* ii (1909) 401.

Var. **angustata** *T. Kirk l.c.*—Leaves narrower than in the type, linear-lanceolate, acute or acuminate.

Auckland and Campbell Islands: Woods near the sea, not uncommon, *Hooker, T. Kirk! Chapman!* Macquarie Island, *A. Hamilton.* Var. *angustata:* Antipodes Island, *T. Kirk!*

A larger plant than the preceding, with more fleshy stems and leaves, larger flowers, and larger and more coarsely tuberculate seeds. It much resembles the European *S. media*, but can always be distinguished by the less-developed inflorescence and by the absence of the pubescent line on the branches.

3. **S. minuta** *T. Kirk Students' Fl.* (1899) 57.—"Annual. Stems $\frac{1}{2}$–1 in. high, narrowly winged, branched, glabrous, ciliate. Leaves ovate, acuminate or acute, narrowed into a short broad petiole; apex callous. Peduncles axillary, 1–2-flowered, with a pair of bracts at the base of the naked pedicels, not diverging. Sepals broadly oblong, obtuse. Petals 5, shorter than the sepals, 2-fid nearly to the base. Stamens 8, rarely 10. Capsule not seen."—*Cheesem. Man. N.Z. Fl.* (1906) 64.

South Island: Mount Stokes, 3000 ft., *J. H. Macmahon!* Westport, on the sea-beach, *Dr. Gaze* (a scrap only).

The specimens of this in Mr. Kirk's herbarium are few and imperfect, and I have consequently reproduced his description. He remarks that it is "distinguished from all forms of *S. parviflora, S. decipiens*, and *S. elatinoides* by the broadly obtuse sepals, and from *S. media* by its solitary or geminate flowers and the absence of the hairy line on the stems and branches." It looks to me much like a reduced form of *S. parviflora*.

4. **S. elatinoides** *Hook. f. Fl. Nov. Zel.* i (1853) 25.—A small glabrous pale-green herb; stems 1–3 in. long, branched, decumbent at the base, ascending or suberect at the tips. Leaves $\frac{1}{10}$–$\frac{1}{5}$ in. long, linear or linear-oblong, acute or subacute, narrowed into a short flat petiole. Flowers small, $\frac{1}{10}$ in. diam., axillary and solitary, sessile or on short peduncles. Sepals ovate-lanceolate or subulate-lanceolate, acuminate, with white scarious margins. Petals absent in all the flowers examined. Stamens 5 or 10. Capsule ovoid, as long as the sepals, 6-valved to the middle. Seeds 6–12, red-brown, covered with large rounded tubercles.—*Handb. N.Z. Fl.* (1864) 23; *T. Kirk Students' Fl.* (1899) 58; *Cheesem. Man. N.Z. Fl.* (1906) 64.

North Island: Hawke's Bay—Lake Rotoatara and Cape Kidnappers, *Colenso.* South Island: Canterbury—Tussock-flats near Ashburton, *H. H. Allan!* Otago—Duntroon, Sowburn, Tuapeka Mouth, Speargrass Flat, *Petrie!* November.

Easily recognized by the small size, narrow leaves, acuminate sepals, almost sessile flowers, and coarsely tubercled seeds. The above description is drawn up from Mr. Petrie's Otago specimens, the plant not having been seen in the North Island since Mr. Colenso's original discovery of it more than sixty years ago. It is very closely allied to the Tasmanian *S. multiflora*, if, indeed, not a form of that species.

5. **S. Roughii** *Hook. f. Handb. N.Z. Fl.* (1864) 23.—An erect or straggling much-branched glabrous and succulent glaucous-green herb 2–6 in. high. Leaves $\frac{1}{2}$–1 in. long, linear, acuminate, fleshy, 1-nerved. Flowers large, green, $\frac{1}{2}$–$\frac{3}{4}$ in. long, $\frac{1}{2}$ in. diam., on short stout terminal peduncles. Sepals very large, almost foliaceous, lanceolate, acuminate, with 3 stout nerves. Petals much shorter than the sepals, cleft almost to the base. Stamens 10. Styles 3. Capsule about $\frac{1}{2}$ as long as the sepals, 6-valved to the base. Seeds 12–20, red-brown, covered with large projecting papillae.—*T. Kirk Students'* Fl. (1899) 58; *Cheesem. Man. N.Z. Fl.* (1906) 64; *Ill. N.Z. Fl.* i (1914) t. 18.

South Island: Nelson—Dun Mountain, *Rough! T. F. C.*; Wairau Gorge, *W. T. L. Travers*; Mount Captain, *T. Kirk!* Clarence Valley and Lake Tennyson, *T. F. C.* Canterbury—Mount Torlesse, *Haast, Petrie, T. F. C.*; Broken River and Upper Waimakariri, *J. D. Enys! T. Kirk! T. F. C.* Southland—Takitimo Mountains, *Crosby Smith.* Altitudinal range 3000–6000 ft. December–February.

A most distinct species. It has a very peculiar fleshy glaucous habit, and is remarkable for its large green flowers, the sepals being unusually long and consequently concealing the short white petals. It appears to be confined to bare shingle-slopes on the higher mountains.

6. **S. gracilenta** *Hook. f. Fl. Nov. Zel.* ii (1853) 326.—A loosely tufted rigid and wiry yellow-green herb 1–5 in. high; stems suberect, slightly scabrid, often matted and interlaced. Leaves opposite, glabrous, $\frac{1}{6}$–$\frac{1}{4}$ in. long, linear-subulate, curved, concave above, smooth and convex below when moist, when dry grooved on each side of the stout midrib; tip rigid, terete, acute; margins thickened, slightly ciliate at the base, not revolute; each stem-leaf with a small fascicle of leaves in its axil. Peduncles springing from the axils of the uppermost leaves, 1–3 in. long, solitary, strict, erect, 1-flowered, 2-bracteolate about the middle. Flowers $\frac{1}{3}$ in. diam., greenish-white. Sepals oblong, acute, with broad membranous margins. Petals 5, rather longer than the sepals, 2-cleft almost to the base. Stamens 5–10. Styles 3. Capsule ovate-oblong, 6-valved; seeds pale-brown, papillose.—*Handb. N.Z. Fl.* (1864) 24; *T. Kirk Students' Fl.* (1899) 58; *Cheesem. Man. N.Z. Fl.* (1906) 65; *Ill. N.Z. Fl.* i (1914) t. 19.

South Island: Not uncommon in mountain districts ascending to 5000 ft. Descends to sea-level at the mouth of the Waitaki River. November–February.

Easily recognized by the strict wiry habit, subulate leaves, and very long erect peduncles.

3. **COLOBANTHUS** Bartling. 1830.

Small densely tufted usually rigid glabrous herbs. Leaves opposite, narrow-linear or subulate, usually imbricate, rigid, cartilaginous, rarely fleshy. Flowers green, solitary, on short or long peduncles. Sepals 4–5, coriaceous, erect. Petals wanting. Stamens 4–5, alternating with the sepals, slightly perigynous. Capsule ovoid or oblong, opening by as many valves as sepals.

A genus of about 20 species, most numerous in New Zealand, but found also on the mountains of South America, in Australia and Tasmania, and in the Antarctic islands. Of the 11 species found in New Zealand, 2 are also found in South America, 1 is said to occur in Australia and Tasmania, and the remaining 8 are endemic.

Colobanthus repens Col. in Trans. N.Z. Inst. xix (1887) 261 and *C. caespitotus* Col. *l.c.* xxvii (1895) 384 are respectively *Sagina procumbens* Linn. and *S. apetala* Linn., as proved by the type specimens in Mr. Colenso's herbarium. It is curious that such an

acute observer as Mr. Colenso should have overlooked that the stamens are opposite to the sepals in both these plants, and not alternate, as in the case in all true *Colobanthi*. Both the above species of *Sagina* are now copiously naturalized throughout the Dominion.

* Flowers tetramerous.

Soft, bright-green. Leaves $\frac{1}{10}$–$\frac{1}{4}$ in., linear, obtuse, almost fleshy. Sepals ovate-lanceolate, obtuse	1. *C. muscoides.*
Branched, leafy. Leaves flaccid, $\frac{1}{4}$–$\frac{2}{3}$ in., acute or mucronate, not acicular. Sepals ovate, obtuse	2. *C. quitensis.*
Leaves spreading, margins thickened. Sepals linear-subulate. Flowers lateral, axillary	3. *C. monticola.*

** Flowers pentamerous.

Leaves loosely imbricate, spreading or recurved, chaffy, acute or shortly acicular. Sepals ovate, acute, about equal to the capsule	4. *C. canaliculatus.*
Leaves grassy, often flaccid, acicular. Sepals ovate, acute or acuminate, but slightly exceeding the capsule	5. *C. crassifolius.*
Leaves rigid, spreading, acicular, much longer than the capsule ..	6. *C. Muelleri.*
Leaves densely imbricated, small, $\frac{1}{10}$–$\frac{1}{5}$ in., obtuse at the tip, with a short acicular point. Sepals about equal to the capsule ..	7. *C. brevisepalus.*
Leaves densely imbricate, $\frac{1}{6}$–$\frac{1}{4}$ in., strict, narrowed into short acicular points. Sepals about equal to the capsule	8. *C. Hookeri.*
Leaves short, strict, erect; calyx broad, the sepals narrowed into long acicular points	9. *C. strictus.*
Leaves densely imbricate, $\frac{1}{4}$–$\frac{3}{4}$ in., curved, narrowed into very long acicular points. Sepals much longer than the capsule ..	10. *C. acicularis.*
Leaves barely imbricate, laxly spreading, membranous, $\frac{1}{4}$–$\frac{1}{2}$ in. long. Peduncles axillary. Sepals linear-subulate, much longer than the capsule	11. *C. Buchanani.*

1. **C. muscoides** *Hook. f. Fl. Antarct.* i (1844) 14.—A soft almost flaccid perfectly glabrous densely tufted bright-green plant, forming large irregular patches. Stems numerous, branched, densely matted and compacted. Leaves closely imbricated, connate at the base, spreading or ascending, $\frac{1}{10}$–$\frac{1}{4}$ in. long, linear from a broad base, obtuse at the tip. Flowers minute, on short peduncles which are sunk amongst the uppermost leaves or shortly exserted in fruit. Sepals 4, ovate-lanceolate, obtuse, concave, obscurely keeled at the back. Capsule shorter than the sepals.—*Handb. N.Z. Fl.* (1864) 25; *T. Kirk Students' Fl.* (1899) 62; *Homb. and Jacq. Voy. au Pôle Sud Bot.* (1852) t. 17; *Cheesem. Man. N.Z. Fl.* (1906) 66.

The Snares, Auckland, Campbell, Antipodes, and Macquarie Islands: Common on rocks near the sea.

Forms rounded patches sometimes 18 in. across, although usually much smaller, the inner part composed of the decaying foliage and stems of old plants, the outside thickly covered with the compacted stems and branches, clothed with bright-green leaves.

C. mollis Oliv. TNZI 56 (1926) 5.

2. **C. quitensis** *Bartl. in Presl Reliq. Haenk.* ii (1830–36) 13, t. 49, f. 2.—A small densely tufted much-branched plant 1–2 in. high, forming rather soft rounded patches. Leaves variable in size, lower sometimes over $\frac{1}{2}$ in. long, upper often very small, $\frac{1}{8}$–$\frac{1}{4}$ in., narrow-linear or linear-subulate, acute or mucronate but not acicular at the tip, connate at the base, flat or concave above, convex beneath; texture soft. Peduncles short, stout, terminal. Flowers $\frac{1}{8}$–$\frac{1}{6}$ in. long. Sepals 4, ovate, broad at the base, obtuse at the tip, rather thick. Capsule $\frac{1}{3}$ shorter than the sepals.—*Hook. f. Handb. N.Z. Fl.* (1864) 24; *T. Kirk Students' Fl.* (1899) 60; *Cheesem. Man. N.Z. Fl.* (1906) 66.

South Island: Nelson—Dun Mountain Range, Mount Arthur, Ragian Mountains, *T. F. C.*; Wairau Mountains, *W. T. L. Travers.* Canterbury—Kowai River, *Haast.* Otago—*Buchanan!* Altitudinal range 1500 ft. to 4500 ft. Also in South America, from Mexico to Cape Horn.

A well-marked species, at once recognized by the soft leaves, which never have acicular points, by the tetramerous flowers, and by the broad obtuse sepals.

3. **C. monticola** *Petrie in Trans. N.Z. Inst.* xliv (1912) 179.—A small densely tufted much-branched plant, forming rounded cushions 1–2 in. diam., perfectly glabrous in all its parts. Leaves closely imbricate all round the branches, spreading, the opposite pairs connate at the base, $\frac{1}{6}$–$\frac{1}{3}$ in. long, linear-subulate, thin and membranous at the base, gradually narrowed upwards into a short acicular point, margins conspicuously thickened, channelled above, convex beneath, veinless. Flowers on short axillary peduncles near the tips of the branchlets, the peduncles elongating in fruit. Sepals 4, linear-subulate, acicular. Stamens 4, barely $\frac{1}{2}$ the length of the sepals. Styles 4. Capsule 4-celled, equalling the calyx when mature.

South Island: Rocky faces of the Sealey Range, Mount Cook district, alt 5500 ft., *Petrie*; Hooker Valley, 3000 ft., *T. F. C.*

Closely related to *C. canaliculatus*, but easily separated by the smaller size, tetramerous flowers, much narrower sepals, and shorter stamens and styles.

4. **C. canaliculatus** *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 357.—A small densely tufted much-branched plant, forming rounded cushions 3–4 in. diam. and 2 in. high, occasionally more laxly branched and open. Leaves in opposite pairs with broad connate sheathing bases, $\frac{1}{8}$–$\frac{1}{5}$ in. long, rigid or chaffy, spreading, subulate, gradually narrowed into an acute or shortly acicular tip, deeply channelled above, convex below, margins thickened. Flowers $\frac{1}{6}$ in., terminating short lateral branchlets in the axils of the uppermost leaves. Sepals 5, broadly ovate, acute or subacute, margins thin and almost translucent. Stamens 5, longer than the sepals. Hypogynous disc reduced to a thickened line. Capsules equal to or rather shorter than the sepals.—*Students' Fl.* (1899) 61; *Cheesem. Man. N.Z. Fl.* (1906) 69. C. squarrosus *Cheesem. in Trans. N.Z. Inst.* xxviii (1896) 534.

South Island: Nelson—Mount Owen, on limestone rocks, alt. 4000 ft., *T. F. C.*, *W. Townson!* Otago—*Buchanan.*

A well-marked plant, the chief characters of which are the short spreading chaffy leaves, either acute or very shortly acicular, the short stout lateral peduncles, and the broadly ovate sepals.

5. **C. crassifolius** *Hook. f. Fl. Antarct.* ii (1847) 248.—A small densely tufted perennial $\frac{1}{2}$–$1\frac{1}{2}$ in. high, rarely more. Leaves in crowded tufts, usually grassy, often flaccid, very variable in length, sometimes 1 in. long, very narrow-linear or filiform, at other times shorter, $\frac{1}{4}$ in., linear-subulate; broad and membranous at the base and sheathing the stem, gradually narrowed upwards, acute or acicular at the tip. Peduncles springing from the centre of the leaf-tufts, longer or shorter than the leaves, usually elongating in the fruiting stage. Sepals 5, ovate, acute or acuminate, as long as or rather longer than the capsule. Capsule broadly ovoid, obtuse.—C. Billardieri *Fenzl. in Ann. Wien Mus.* i (1836) 49 (*in part*); *Hook. f. Fl. Antarct.* i (1844) 14; *Fl. Nov. Zel.* i (1853) 27; *Fl. Tasm.* i (1860) 45; *Handb. N.Z. Fl.* (1864) 25; *Benth. Fl. Austral.* i (1863) 161; *T. Kirk Students' Fl.* (1899) 60; *Cheesem. Man. N.Z. Fl.* (1906) 67.

Var. **alpinus** *T. Kirk l.c.* — Larger, forming tufts sometimes 4 in. diam. Leaves 1–2 in., with acicular tips. Peduncles 2–4 in. long in fruit. Sepals ovate, acuminate, rather longer than the capsule.

North Island: From Mount Egmont, Tongariro and Ruapehu, and Mount Hikurangi, southwards along the Kaimanawa Mountains, the Ruahine Range, and the Tararua Mountains. South Island, Stewart Island, Chatham Islands, Auckland and Campbell Islands, Antipodes Island, Macquarie Island: Altitudinal range from sea-level to 5000 ft.

C. crassifolius is usually considered to be the same as a Victorian and Tasmanian plant. But Dr. Skottsberg, who is well acquainted with the genus, has lately reaffirmed its distinctness. He unites the New Zealand plant with the Fuegian and Antarctic *C. crassifolius*, and I am following his views in this place.

C. crassifolius is separated from *C. quitensis* by the different habit, acicular tips to the leaves, pentamerous flowers, and pointed sepals. From *C. Muelleri* it can be distinguished by the grassy and often flaccid leaves and shorter sepals, which last are not acicular; but some forms are very difficult to place.

6. **C. Muelleri** *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 356.—A small densely tufted perfectly glabrous plant, $\frac{1}{4}$–$1\frac{1}{2}$ in. high. Leaves rigid, cartilaginous, spreading, often recurved, $\frac{1}{4}$–$\frac{3}{4}$ in. long, linear-subulate, broadly channelled above, convex below, narrowed into short acicular tips. Peduncles terminal or lateral, $\frac{1}{4}$–$\frac{3}{4}$ in. long, stout, often hidden among the leaves. Sepals 5, ovate or ovate-lanceolate, suddenly narrowed into cartilaginous points with acicular tips, about $\frac{1}{3}$ longer than the capsule.—*Students' Fl.* (1899) 60; *Cheesem. Man. N.Z. Fl.* (1906) 67. C. Billardieri *var.* brachypoda *F. Muell. Veg. Chath. Is.* (1864) 11.

? Var. **multicaulis** *T. Kirk Students' Fl.* (1899) 61. — Rigid, much branched, branches naked below. Leaves rather lax, spreading, linear-subulate, $\frac{1}{4}$ in. long. Peduncles about as long as the leaves. Sepals narrow-ovate, acute or mucronate, equalling the capsule.

North and South Islands, Stewart Island, Chatham Islands: The typical form not uncommon from Manaia (Taranaki), *Mrs. F. Mason!* and the East Cape southwards, usually on cliffs and shingly beaches. Var. *multicaulis:* Interior of Otago, *Buchanan!*

A puzzling plant. As characterized above, it is distinguished from *C. Billardieri* by the rigid habit, harsh often cartilaginous leaves, and especially by the rigid acicular sepals, which are much longer than the capsule. The var. *multicaulis* is only known from a mere scrap collected somewhere in Central Otago by Mr. Buchanan, and probably does not belong to this species.

7. **C. brevisepalus** *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 357, t. 27E.—A small densely tufted much-branched plant, forming compact rounded cushions 1–2 in. diam. Leaves densely imbricated, straight or curved, smooth and shining, $\frac{1}{8}$–$\frac{1}{5}$ in. long, base broad and membranous, sheathing the stem, suddenly narrowed into the upper part, which is subulate, concave above, convex below, obtuse and almost tumid at the tip, abruptly produced into a short acicular point. Flowers terminal, sunk amongst the leaves. Sepals 5, ovate-subulate, convex or almost keeled, equalling or slightly longer than the oblong capsule.—*Students' Fl.* (1899) 61; *Cheesem. Man. N.Z. Fl.* (1906) 68.

South Island: Marlborough—Mount Blairich, *J. H. Macmahon!* Mount Mowatt, *T. Kirk!* Canterbury—Lake Heron and Mount Arrowsmith, *Cockayne;* Mount Dobson and other mountains near Lake Tekapo, *T. F. C.* Otago—Kurow, Speargrass Flat, Cromwell, Queenstown, *Petrie!* Eyre Mountains, *Poppelwell.* Ascends to 6000 ft.

This appears to be a well-marked form, recognized without any difficulty by the short densely imbricated leaves with obtuse tips furnished with a fine hair-point.

8. **C. Hookeri** *Cheesem. in Trans. N.Z. Inst.* liii (1921) 425.—A small densely tufted moss-like plant, forming small rounded patches 1–1½ in. high, smooth and glabrous in all its parts. Leaves closely imbricate, ⅙–¼ in. long, strict and rigid, subulate, tapering from the base to a shortly acicular apex, channelled above, convex below, sometimes with a groove between the midrib and the margin. Flowers terminal, solitary; peduncles short, the flowers slightly exceeding the uppermost leaves. Sepals 5, ovate-subulate, thickened at the base, acute or very shortly mucronate, equalling or very slightly exceeding the capsule. Stamens always 5.—Colobanthus subulatus *Hook. f. Fl. Antarct.* i (1844) 13 (*but not* Sagina subulata *D'Urv. Fl. Ins. Mal.* (1826) 617); *Handb. N.Z. Fl.* (1864) 25; *nor* C. Benthamianus *Fenzl. in Ann. Wien Mus.* i (1838) 49.

Auckland and Campbell Islands: *Hooker, T. Kirk! B. C. Aston!*

In the "Subantarctic Islands of New Zealand" (ii, p. 402) I pointed out that the plate of *C. subulatus* given in the "Flora Antarctica" (ii, t. 47) represents a plant with a much more lax habit than the Auckland Islands or Campbell Island species, and that the sepals were only four in number, instead of five. I have therefore separated the New Zealand plant as a distinct species.

I have not seen any South Island specimens that I can refer to this species, although three are quoted by Hooker. Possibly they represent small states of *C. acicularis.*

9. **C. strictus** *Cheesem. in Trans. N.Z. Inst.* liii (1921) 424.—A perfectly glabrous and densely tufted rigid plant, forming hemispherical cushions 1–3 in. diam. Leaves numerous, densely imbricated all round the branches, straight or slightly curved, strict, erect, broad and membranous and sheathing the branch at the base, above rigid and coriaceous and gradually narrowed into a straight acicular apex, channelled above, convex beneath. Peduncles terminating the branchlets, stout, shorter than the leaves, stiffly erect. Sepals 5, broadly ovate at the base, suddenly narrowed into long acicular points ½ as long again as the capsule.—C. Muelleri *var.* strictus *Cheesem. Man. N.Z. Fl.*(1906) 68.

South Island: Upper Clarence Valley, *T. F. C.*; shingly flats in the Tasman and Hooker Valleys, *T. F. C*; Dunstan Mountains, *Petrie!* Altitudinal range 2500–3500 ft.

In the first edition of this work I treated this as a variety of *C. Muelleri.* But since then I have had opportunities of studying it in the Mount Cook district, where it is not uncommon, and have now no hesitation in constituting it a distinct species. It is mainly distinguished by the short strict erect leaves, and broad calyx-lobes, which are suddenly narrowed into long acicular points, much exceeding the capsule.

10. **C. acicularis** *Hook. f. Handb. N.Z. Fl.* (1864) 25.—A perfectly glabrous densely tufted rigid and shining plant, forming green or brownish rounded tufts 3–6 in. diam. and 1–3 in. high. Leaves very numerous, densely imbricated all round the branches, ¼–¾ in. long, linear-subulate, often curved, broad and sheathing at the base, gradually narrowed into very long acicular points, channelled above, convex and smooth below. Flowers almost sessile amongst the uppermost leaves, than which they are shorter. Sepals 5, narrow linear-subulate, narrowed into long acicular tips, at least ⅓ longer than the capsule.—*T. Kirk Students' Fl.* (1899) 62; *Cheesem. Man. N.Z. Fl.* (1906) 66; *Ill. N.Z. Fl.* i (1914) t. 20A.

South Island: Dry rocky places in the mountains, abundant throughout. Altitudinal range from 1500 to 6000 ft.

Well characterized by the robust stems and branches, long leaves with remarkably long acicular points, almost sessile flowers, and long sepals, which much exceed the capsule.

11. **C. Buchanani** *T. Kirk in Trans. N.Z. Inst.* xxvii (1895) 358, t. 27D.—Apparently a laxly tufted plant 2–3 in. high, with slender erect stems. Leaves not imbricating, loosely spreading, $\frac{1}{4}$–$\frac{1}{2}$ in. long, linear-subulate, sheathing at the base, membranous, concave above, convex below, gradually narrowed into short acicular points. Peduncles axillary, slender, usually rather longer than the leaves. Flowers $\frac{1}{5}$–$\frac{1}{4}$ in. long. Sepals 5, linear-subulate, acuminate, $\frac{1}{2}$ as long again as the short capsule.—*Students' Fl.* (1899) 62; *Cheesem. Man. N.Z. Fl.* (1906) 69.

South Island: Otago—Manuherikia Valley, *Buchanan!*

A most distinct plant, of which I have only seen three imperfect specimens. The slender stems, loosely spreading membranous leaves, and axillary peduncles give it a very different aspect from that of any other New Zealand species.

4. SPERGULARIA Pers. 1819.

Spreading or prostrate herbs. Leaves linear or setaceous, often with smaller ones fascicled in the axils so as to appear verticillate. Stipules small, scarious. Flowers white or pink, pedicelled, in subracemose cymes. Sepals 5. Petals 5, entire, rarely wanting. Stamens 10 or fewer by abortion. Ovary 1-celled, many-ovuled; styles 3. Capsules 3-valved; seeds compressed, often winged.

A genus of 5 or 6 species, widely spread in temperate or subtropical regions, chiefly near the sea-coast or in saline localities. The single New Zealand species has a very extensive range.

1. **S. media** (L.) *Presl Fl. Sic.* (1826) 17.—A rather succulent much-branched prostrate or suberect herb, more or less viscid-pubescent; stems 2–6 in. long. Leaves narrow-linnear, semi-terete, $\frac{1}{3}$–1 in. long, fleshy, quite entire, acute; stipules broadly ovate, acuminate, conspicuous. Flowers many, axillary and terminal, on slender glandular peduncles $\frac{1}{3}$–1 in. long. Sepals lanceolate, with a broad white membranous border. Petals usually shorter than the sepals. Capsule exceeding the sepals. Seeds more or less flattened, often surrounded by a broad membranous wing.—*T. Kirk Students' Fl.* (1899) 63; *Cheesem. Man. N.Z. Fl.* (1906) 70. S. rubra *var.* marina *Hook. f. Handb. N.Z. Fl.* (1864) 25. Arenaria media *Linn. Sp. Plant.* (1753) 606; *A. Cunn. Precur.* (1839) n. 609; *Hook. f. Fl. Nov. Zel.* i (1853) 26.

North and South Islands, Stewart Island: Common on the coast, from the Three Kings Islands and the North Cape southwards. October–February. An abundant plant near the sea in many parts of the world.

The allied species *S. rubra* Presl, which has more slender and flatter leaves, smaller flowers, and seeds not so conspicuously margined, is naturalized in several places in both the North and South Islands, but is usually found in inland localities.

5. HECTORELLA Hook. f. 1864

A small densely tufted glabrous perennial. Leaves small, densely imbricated, coriaceous, entire. Flowers almost sessile amongst the uppermost leaves. Sepals 2, short, truncate. Petals 5, connate at the base, thickened below the tip. Stamens 5, inserted on the tube of the corolla, and alternate with the petals; anthers linear-oblong. Ovary free; ovules 4–5, erect from the base of the cell; funicles slender; style erect; stigmas 1–3, linear, papillose. Capsule membranous, equalling the sepals; seeds 2–4.

A monotypic genus confined to New Zealand; not closely allied to any other.

1. **H. caespitosa** *Hook. f. Handb. N.Z. Fl.* (1864) 27.—Stems short, stout, densely tufted, with the leaves on almost as thick as the little finger, forming compact rounded cushions 2–8 in. diam. and 1–3 in. high. Leaves very numerous, closely imbricated in many series, $\frac{1}{6}$–$\frac{1}{3}$ in. long, broadly triangular-ovate to linear-oblong with a broad base, thin and membranous below the middle, coriaceous and keeled above; margins and tip thickened; veins reticulated. Flowers small, white, very shortly peduncled, forming a ring round the top of the branches among the uppermost leaves, often unisexual, the staminate ones being the smallest. Sepals concave, keeled. Petals much longer than the sepals. Capsule globose, membranous, as long as the sepals. Seeds 2–4, broadly ovoid, smooth and shining.—*Hook. f. in Ic. Plant.* (1867–71) t. 1046; *T. Kirk Students' Fl.* (1899) 65; *Cheesem. Man. N.Z. Fl.* (1906) 72. H. elongata *Buch. in Trans. N.Z. Inst.* xvi (1884) 395, t. 35.

South Island: Canterbury—Mountains above Arthur's Pass, *T. F. C.*; Upper Waimakariri, *Cockayne*; Mount Arrowsmith, *Cockayne* and ***R. M. Laing***; Mount Cook district, *F. G. Gibbs, T. F. C.* Westland—Haast Pass and Makaroro, *Poppelwell.* Otago—Mount Alta and Mount Aspiring, *Hector* and *Buchanan!* Hector Mountains, Dunstan Mountains, and all high mountains west of the Clutha River, *Petrie*; Eyre Mountains, *Poppelwell*; Garvie Mountains, *Crosby Smith.* Altitudinal range from 4000 to 7000 ft.

A very curious and interesting little plant, which was placed by Hooker in the *Portulacaceae*, although he admitted that it is not allied to any genus in the family. A few years ago its systematic position was investigated by Dr. J. Ewart, of Melbourne, who pointed out that it was undoubtedly related to the genus *Lyallia*, of Kerguelen Island. He therefore suggested that it should be removed from *Portulacaceae* and placed in the *Caryophyllaceae*, in the vicinity of *Lyallia* and *Pycnophyllum*. I am following his suggestion in this work.

Illecebraceae Hutch.

6. SCLERANTHUS Linn.

Small rigid usually densely tufted annual or perennial herbs. Leaves opposite, connate at the base, subulate, often serrulate; stipules wanting. Flowers small, green, axillary, solitary or 2 together, or in little cymes or fascicles. Perianth funnel-shaped or urceolate or turbinate, 4–5-toothed or -lobed. Stamens 1, 2, 5, or 10, inserted on the throat of the perianth; filaments subulate; anthers didymous. Ovary ovoid; styles 2, distinct; stigmas capitellate. Fruit a membranous utricle enclosed in the persistent and hardened perianth. Seed lenticular; testa smooth; embryo annular.

Species about 12, scattered through Europe, temperate and subtropical Asia, Africa, and Australasia. The single New Zealand species is also found in Australia.

The systematic position of *Scleranthus* has long been a matter for discussion. Bentham and Hooker placed it in the *Illecebraceae*, but long ago F. Mueller suggested its removal to the *Caryophyllaceae*, to which it is certainly very closely allied. This view has been accepted by Pax, who in the "Pflanzenfamilien" has transferred the whole family *Illecebraceae* to *Caryophyllaceae*.

(Forst.)

1. **S. biflorus** *Hook. f. Fl. Nov. Zel.* i (1853) 74.—A small densely branched glabrous or minutely pubescent perennial herb, usually forming compact cushions 1–4 in. diam. or more, rarely laxly branched with the stems creeping and elongating to 6 in. Leaves crowded and imbricating, rarely remote, $\frac{1}{10}$–$\frac{1}{12}$ in. long, narrow-linear, acute, concave, minutely serrulate, coriaceous. Peduncles axillary, solitary, very short in the flowering stage, but lengthening in fruit and overtopping the leaves. Flowers minute, in pairs or more rarely solitary at the top of the peduncle, sessile within

S. lyallii var. uniflorus Cheesem. N.Z.J.S.T. 8:372. 1926.

4 minute concave bracts placed crosswise. Perianth 4-lobed. Stamen 1, inserted on an annular membrane near the mouth of the perianth. Fruiting-perianth about $\frac{1}{12}$ in. long, hard, ovoid at the base; lobes erect. Utricle membranous, included.—*Handb. N.Z. Fl.* (1864) 234; *Benth. Fl. Austral.* v (1870) 259; *Cheesem. Man. N.Z. Fl.* (1906) 575. Mniarum biflorum *Forst. Char. Gen.* (1786) 2, t. 1; *Forst. f. Prodr.* (1786) n. 6; *A. Rich. Fl. Nouv. Zel.* (1832) 319; *A. Cunn. Precur.* (1839) n. 368; *Raoul Choix* (1846) 43. M. fasciculatum *Raoul l.c.* (*not of R. Br.*). Ditoca muscosa *Banks ex Gaertn. Fruct.* ii (1791) 196, t. 126.

North and South Islands, Stewart Island: Abundant throughout, from the Three Kings Islands and the North Cape to Foveaux Strait. Sea-level to 4000 ft.

Family XL. RANUNCULACEAE.

Annual or perennial herbs, rarely shrubs or woody climbers. Leaves all radical or alternate, seldom opposite (*Clematis*). Stipules wanting, or adnate to the petiole. Flowers regular or irregular, hermaphrodite or more rarely unisexual. Sepals 3 or more, usually 5, deciduous, often petaloid, imbricate (valvate in *Clematis*). Petals the same number as the sepals or more, hypogynous, free, imbricate, sometimes wanting. Stamens hypogynous, usually very numerous; anthers adnate. Carpels generally many, free, 1-celled; ovules one or several, attached to the ventral suture, anatropous. Fruit of numerous 1-seeded indehiscent achenes or many-seeded follicles, rarely a berry. Seeds small; embryo minute, at the base of copious albumen.

A large family, most abundant in temperate regions; rare within the tropics. Genera 30; species about 550. Most of the species are acrid, and many are poisonous, Aconite and Hellebore being familiar examples. All the New Zealand genera are widely distributed in temperate climates.

Woody climbers with opposite compound leaves. Sepals petaloid, valvate. Petals wanting	1. Clematis.
Minute herbs with radical linear leaves. Petals wanting. Carpels with a single pendulous ovule. Achenes in an elongated spike	2. Myosurus.
Herbs. Sepals deciduous. Petals 3 to many. Carpels with a single erect ovule	3. Ranunculus.
Herbs with radical sagittate leaves. Sepals petaloid. Petals wanting. Carpels with several ovules	4. Caltha.

1. CLEMATIS Linn. 1737

Climbing undershrubs with slender flexuous branches, rarely dwarf and prostrate. Leaves opposite, usually ternately divided into 3 stalked leaflets, which are either entire or more often variously lobed or cut; petioles often twining. Flowers in few- or many-flowered axillary panicles, dioecious in the New Zealand species. Sepals 4–8, petaloid, valvate in the bud. Petals wanting. Stamens many. Carpels numerous, each with one pendulous ovule. Fruit a head of sessile achenes, in all the New Zealand species produced into long feathery persistent styles.

A genus of over 150 species, found in most temperate climates, rare in the tropics. The New Zealand species are all endemic, and all possess once- or twice-ternately divided leaves and dioecious flowers, the males without any carpels, the females usually with a few imperfect stamens. Most of them vary greatly in the foliage, especially the large-leaved species. These in their normal state have 3-foliolate leaves with the

leaflets toothed or lobed, but all run into varieties in which the leaves are biternate or decompound, the ultimate segments being much reduced in size. These forms are most difficult of discrimination, especially when in a flowerless condition, and some of them are probably not permanent states.

A. Sepals white.

Large and stout. Leaflets usually entire. Flowers 2–4 in. diam. . . 1. *C. indivisa.*
Slender, pale-green. Leaflets toothed or lobed. Flowers 1–1½ in. diam. . . . . 2. *C. hexasepala.*
Small, slender. Leaflets pinnate or pinnately divided. Flowers ½–1 in. diam. . . . . 3. *C. australis.*

B. Sepals yellowish or greenish-yellow (purplish in C. quadribracteolata).

* Sepals usually 6 (5–8). Leaflets usually large and well developed.

Slender. Leaflets glabrous or nearly so, toothed or lobed. Flowers greenish-yellow. Sepals silky . . . . . 4. *C. Colensoi.*
Stout. Leaflets coriaceous, pubescent, toothed or lobed. Flowers yellow. Sepals densely tomentose . . . . . 5. *C. foetida.*
Slender. Leaflets thin, silky-pubescent, often entire. Flowers yellow. Sepals silky. Anthers broad, tipped with a minute appendage . . . . . 6. *C. parviflora.*

** Sepals 4. Leaflets minute, wanting in *C. afoliata.*

Usually leafless. Flowers greenish-white, ½–¾ in. diam. . . 7. *C. afoliata.*
Slender, brownish-green. Leaflets minute, ⅙–½ in. long, entire or toothed. Flowers yellow, ½ in. diam. . . . . 8. *C. marata.*
Very slender. Leaflets minute, usually linear. Flowers purplish, ⅓–½ in. diam. Sepals narrow-linear . . . . . 9. *C. quadribracteolata.*

paniculata J.F. Gmelin 1791. Linn. Syst. Nat.

1. **C. indivisa** *Willd. Sp. Plant.* ii (1799) 1291.—A large woody climber, often covering bushes or small trees. Stems stout, frequently as thick as a man's arm. Leaves of adult plants 3-foliolate, coriaceous, glabrous; leaflets 1–4 in. long, all stalked, ovate-oblong or ovate-cordate, rarely narrower and linear-oblong, lobed or more commonly entire. Leaves of seedling plants narrow-linear, 3–4 in. long, ¼–½ in. broad. These are followed by trifoliolate leaves with linear leaflets, which in their turn are succeeded by others in which the leaflets are broader, and much cut and lobed, the leaves occasionally being twice ternate. Flowers in axillary panicles, most abundantly produced, large, white, 2–4 in. diam., the males much the largest. Sepals 6–8, oblong. Anthers oblong, obtuse. Achenes numerous, downy, with a plumose tail often more than 2 in. long.—*A. Rich. Fl. Nouv. Zel.* (1832) 288; *A. Cunn. Precur.* (1838) n. 635; *Raoul Choix* (1846) 47; *Hook. f. Fl. Nov. Zel.* i (1853) 6; *Handb. N.Z. Fl.* (1864) 2; *T. Kirk Students' Fl.* (1899) 2; *Cheesem. Man. N.Z. Fl.* (1906) 2; *Ill. N.Z. Fl.* i (1914) t. 1. C. integrifolia *Forst. f. Prodr.* (1786) n. 231 (*but not of Linn. Sp. Plant.* (1753) 544).

North and South Islands, Stewart Island: Abundant throughout. Sea-level to 2500 ft. *Puawhananga.* August–November.

I have elsewhere proved (Trans. N.Z. Inst. xlvi (1914) 1) that Kirk's two varieties *lobulata* and *linearis* represent the foliage of young plants.

2. **C. hexasepala** *DC. Syst.* i (1818) 146.—Much smaller and more slender than *C. indivisa.* Leaves 3-foliolate, pale-green, coriaceous, glabrous; leaflets 1–3 in. long, stalked, narrow ovate-oblong or ovate-cordate, acute or acuminate, usually irregularly toothed or lobed, rarely entire. Flowers numerous, 1–1½ in. diam., white. Sepals 6–8, linear-oblong, obtuse, downy. Anthers long, linear, obtuse. Achenes numerous, narrow-ovoid, pilose.—

var. rutaefolia Hook. f. Fl. N.Z. 1 : 7.

North Island: From the Kaipara Harbour to Cook Strait, not uncommon, especially in the Upper Waikato and Taupo districts. South Island: Queen Charlotte Sound, *Forster ;* near Moutere (Nelson), *T. F. C.* Recorded from Canterbury (*J. B. Armstrong*), Otago (*Lindsay*), and the Bluff Hill (*T. Kirk*). *Pikiarero.* September–November.

Easily separated from *C. indivisa* by the smaller size, narrower pale-green leaves, which are almost always toothed, and by the smaller flowers. The leaves of the young plants pass through the same changes as those of *C. indivisa.*

3. **C. australis** *T. Kirk Students' Fl.* (1899) 3.—Stems and branches slender, much branched, glabrous or pubescent at the tips. Leaves 3-foliolate, glabrous, somewhat coriaceous (especially in the small-leaved forms) ; leaflets very variable in size, $\frac{1}{3}$–1 in. long, pinnate or pinnately lobed, segments or lobes usually again toothed or lobed. Flowers white, $\frac{1}{2}$–1 in. diam., in few-flowered panicles or solitary on long slender peduncles clustered in the axils of the leaves. Sepals 5–8, downy. Achenes narrowed into the style, usually pilose, sometimes glabrous when fully mature.—*Cheesem. Man. N.Z. Fl.* (1906) 3.

South Island: Hilly and mountain districts in Nelson and Canterbury, not uncommon. 500–3500 ft. November–January.

A puzzling plant, large states of which can only be separated from *C. hexasepala* by the pinnately divided leaflets, while smaller forms come very nearly to *C. Colensoi* var. *rutaefolia,* from which, however, it can usually be distinguished by the larger white flowers and more pointed sepals.

4. **C. Colensoi** *Hook. f. Handb. N.Z. Fl.* (1864) 2.—Stems and branches slender, glabrous or silky at the tips. Leaves 3-foliolate, mem- [illegible] leaflets stalked, 1–11 in. long, crenate-

Is Clematis colensoi, Hook.f. a true species?

T.N.Z.I. vol. 57, p. 50. Ckn. & Allan.

Clematis australis, T. Kirk.

"....the flowers are invariably yellow."

Ckn. & Allan in T.N.Z.I. vol. 57, p. 50.

5. **C. foetida** *Raoul Choix* (1846) 25, t. 22.—Stems stout, woody ; branches numerous, intertwined, often covering bushes or small trees ; young shoots clothed with fulvous pubescence. Leaves 3-foliolate, slightly coriaceous, usually thinly pubescent on both surfaces, but often becoming glabrous when old ; leaflets 1–2 in. long, all stalked, ovate or ovate-cordate,

leaflets toothed or lobed, but all run into varieties in which the leaves are biternate or decompound, the ultimate segments being much reduced in size. These forms are most difficult of discrimination, especially when in a flowerless condition, and some of them are probably not permanent states.

Usually leafless. Flowers greenish-white, ½–¾ in. diam. .. 7. *C. afoliata.*
Slender, brownish-green. Leaflets minute, ⅙–½ in. long, entire or toothed. Flowers yellow, ½ in. diam. .. .. .. 8. *C. marata.*
Very slender. Leaflets minute, usually linear. Flowers purplish, ⅓–½ in. diam. Sepals narrow-linear .. .. .. 9. *C. quadribracteolata.*

paniculata J.F. Gmelin. 1791. Linn. Syst. Nat.

1. **C. indivisa** *Willd. Sp. Plant.* ii (1799) 1291.—A large woody climber, often covering bushes or small trees. Stems stout, frequently as thick as a man's arm. Leaves of adult plants 3-foliolate, coriaceous, glabrous; leaflets 1–4 in. long, all stalked, ovate-oblong or ovate-cordate, rarely narrower and linear-oblong, lobed or more commonly entire. Leaves of seedling plants narrow-linear, 3–4 in. long, ¼–½ in. broad. These are followed by trifoliolate leaves with linear leaflets, which in their turn are succeeded by others in which the leaflets are broader, and much cut and lobed, the leaves occasionally being twice ternate. Flowers in axillary panicles, most abundantly produced, large, white, 2–4 in. diam., the males much the l
numerous,

A. Cunn. Precur. (1838) n. 637 ; *Raoul Choix* (1846) 47 ; *Hook. f. Handb. N.Z. Fl.* (1864) 2 ; *T. Kirk Students' Fl.* (1899) 3 ; *Cheesem. Man. N.Z. Fl.* (1906) 3. C. hexapetala *Forst. f. Prodr.* (1786) n. 230 ; *A. Rich. Fl. Nouv. Zel.* (1832) 288. C. Forsteri *Gmel. Syst.* (1791) 873. C. Colensoi *Hook. f. Fl. Nov. Zel.* i (1853) 6, t. 1 (*not of Handb. N.Z. Fl.*).

North Island: From the Kaipara Harbour to Cook Strait, not uncommon, especially in the Upper Waikato and Taupo districts. South Island: Queen Charlotte Sound, *Forster ;* near Moutere (Nelson), *T. F. C.* Recorded from Canterbury (*J. B. Armstrong*), Otago (*Lindsay*), and the Bluff Hill (*T. Kirk*). *Pikiarero.* September–November.

Easily separated from *C. indivisa* by the smaller size, narrower pale-green leaves, which are almost always toothed, and by the smaller flowers. The leaves of the young plants pass through the same changes as those of *C. indivisa.*

3. **C. australis** *T. Kirk Students' Fl.* (1899) 3.—Stems and branches slender, much branched, glabrous or pubescent at the tips. Leaves 3-foliolate, glabrous, somewhat coriaceous (especially in the small-leaved forms) ; leaflets very variable in size, $\frac{1}{3}$–1 in. long, pinnate or pinnately lobed, segments or lobes usually again toothed or lobed. Flowers white, $\frac{1}{2}$–1 in. diam., in few-flowered panicles or solitary on long slender peduncles clustered in the axils of the leaves. Sepals 5–8, downy. Achenes narrowed into the style, usually pilose, sometimes glabrous when fully mature.—*Cheesem. Man. N.Z. Fl.* (1906) 3.

South Island: Hilly and mountain districts in Nelson and Canterbury, not uncommon. 500–3500 ft. November–January.

A puzzling plant, large states of which can only be separated from *C. hexasepala* by the pinnately divided leaflets, while smaller forms come very nearly to *C. Colensoi* var. *rutaefolia*, from which, however, it can usually be distinguished by the larger white flowers and more pointed sepals.

4. **C. Colensoi** *Hook. f. Handb. N.Z. Fl.* (1864) 2.—Stems and branches slender, glabrous or silky at the tips. Leaves 3-foliolate, membranous or slightly coriaceous ; leaflets stalked, $\frac{1}{3}$–$1\frac{1}{4}$ in. long, crenate, unequally toothed or 3-lobed, or again ternately or pinnately divided. Flowers greenish-yellow, $\frac{1}{2}$–1 in. diam., in few- or many-flowered panicles, or more usually solitary on slender peduncles fascicled in the axils of the leaves. Sepals 5–8, oblong, silky. Anthers linear. Achenes silky or sometimes nearly glabrous when mature.—*T. Kirk Students' Fl.* (1899) 3 ; *Cheesem. Man. N.Z. Fl.* (1906) 3. C. hexasepala *Hook. f. Fl. Nov. Zel.* i (1853) 7 (*not of DC.*).

Var. **rutaefolia** *Hook. f. Fl. Nov. Zel.* i (1853) 7.—Leaves biternate or bipinnate ; secondary leaflets often stalked. Usually smaller than the type.

North Island: Both varieties common about Wellington, and extending northward to Hawke's Bay and Cape Egmont. South Island: Nelson—Wairau Valley, Buller Valley, *T. F. C.* Canterbury—Kowai River, *Petrie !* Ashley Gorge, *Cockayne !* Sea-level to 3000 ft. November–January.

A variable plant, not always readily distinguishable from states of *C. hexasepala* or *C. australis.*

5. **C. foetida** *Raoul Choix* (1846) 23, t. 22.—Stems stout, woody ; branches numerous, intertwined, often covering bushes or small trees ; young shoots clothed with fulvous pubescence. Leaves 3-foliolate, slightly coriaceous, usually thinly pubescent on both surfaces, but often becoming glabrous when old ; leaflets 1–2 in. long, all stalked, ovate or ovate-cordate,

acute or acuminate, entire or irregularly toothed or lobed. Panicles large, much divided; branches usually densely clothed with pale or fulvous tomentum. Flowers very numerous, small, ½–¾ in. diam., yellowish, strongly odorous but certainly not foetid. Sepals 6–8, linear, obtuse or acute, densely tomentose on the outside. Anthers linear-oblong, obtuse. Achenes narrow-ovoid, very silky, narrowed into short plumose tails.—*Hook. f. Fl. Nov. Zel.* i (1853) 7; *Handb. N.Z. Fl.* (1864) 2; *T. Kirk Students' Fl.* (1899) 4; *Cheesem. Man. N.Z. Fl.* (1906) 4. C. Parkinsonia *Col. in Trans. N.Z. Inst.* xii (1880) 359, xiv (1882) 331.

North and South Islands: Not uncommon in lowland districts from the North Cape to the south of Otago. September–November.

Varies considerably in size, texture, cutting of the leaves, degree of pubescence, &c.; but can always be recognized by the pale or fulvous pubescence on the leaves, young shoots, and branches of the panicle, by the small yellow flowers, which are usually produced in enormous numbers, and by the dense tomentum on the sepals. The type specimens of Mr. Colenso's *C. Parkinsoniana*, preserved in his herbarium, show no points of difference from the ordinary form of *C. foetida*.

6. **C. parviflora** *A. Cunn. Precur.* (1838) n. 636.—More or less clothed with silky fulvous pubescence. Stems slender, wiry, not nearly so robust or so much branched as in the preceding species. Leaves 3-foliolate, thin and almost membranous, more rarely subcoriaceous, tawny-pubescent, especially on the veins and under-surface; leaflets ½–1½ in. long, all stalked, ovate or ovate-cordate, usually entire but occasionally irregularly lobed, subacute. Panicles slender, branched; rhachis and pedicels tawny-pubescent. Flowers small, ½–¾ in. diam., yellowish. Sepals 6–8, linear, more or less clothed with silky pubescence. Anthers short and broad, oblong, with a minute appendage at the apex of the connective. Achenes narrow-ovoid, silky.—*Raoul Choix* (1846) 47; *Hook. f. Fl. Nov. Zel.* i (1853) 7; *Handb. N.Z. Fl.* (1864) 2; *T. Kirk Students' Fl.* (1899) 4; *Cheesem. Man. N.Z. Fl.* (1906) 4; *Ill. N.Z. Fl.* i (1914) t. 4. C. Hillii *Col. in Trans. N.Z. Inst.* xxxi (1899) 266.

Var. **depauperata** *Hook. f. Handb. N.Z. Fl.* (1864) 2.—Leaflets very small. Sepals narrowed into long slender points.

Var. **trilobata** *T. Kirk Students' Fl.* (1899) 5.—Leaflets deeply 3-lobed; lobes entire or cut. Flowers smaller. Sepals more pubescent.

North Island: The typical form in various localities from the Three Kings Islands and the North Cape to Hawke's Bay, but often local. Var. *trilobata:* Bay of Islands, *T. Kirk!* Northern Wairoa, *T. F. C.;* Te Aroha, *T. F. C.;* between Gisborne and Napier, *Bishop Williams!* South Island: Var. *depauperata:* Nelson, *W. T. L. Travers.* Var. *trilobata:* Okarito, *A. Hamilton.* Sea-level to 1500 ft. September–November.

A handsome species, closely allied to *C. foetida*, but at once distinguished by the smaller size, more slender habit, smaller and thinner usually entire leaflets, narrower silky sepals, and especially by the broad anthers, which have a minute swelling at the tip of the connective. I have not seen specimens of Hooker's var. *depauperata.*

7. **C. afoliata** *Buch. in Trans. N.Z. Inst.* iii (1871) 211.—Stems and branches leafless, wiry, striate, glabrous, often much intertwined. Leaves usually reduced to petioles in the mature plant, when present consisting of 3 minute long-stalked ovate or triangular leaflets; in young plants more frequently developed and rather larger. Flowers greenish-white, ½–¾ in. diam., in fascicles of 2–5 in the axils of the petioles; peduncles slender, pilose, each with a pair of minute ovate bracteoles. Sepals 4,

R. maculatus Cheesem. & Allan. 56 : 33
R. cessi Petrie 56 : 11

ovate- or oblong-lanceolate, usually acute, silky. Anthers linear. Achenes ovoid, silky.—*T. Kirk Students' Fl.* (1899) 3; *Cheesem. Man. N.Z. Fl.* (1906) 5. C. aphylla *Col. in Trans. N.Z. Inst.* xix (1887) 259.

North Island: Hawke' Bay—Puketapu, *H. Hill!* South Island: Marlborough—Near Picton, *J. Rutland! Buchanan!* Awatere Valley, *Cockayne.* Nelson—Hanmer Plains, *H. J. Matthews!* Waiau Valley, *T. Kirk!* Canterbury—*N. T. Carrington!* Weka Pass, *Cockayne;* Waitaki Valley, *Buchanan, Petrie!* Otago—Duntroon, *Petrie!* Southland—Kingston, *Crosby Smith.*

A very curious plant, often forming dense masses of intertwined stems and branches several feet in length.

8. **C. marata** *J. B. Armstr. in Trans. N.Z. Inst.* xiii (1881) 335.—Stems slender, much branched, often forming dense interlaced masses scrambling over bushes or among grass, brownish-green, pubescent, grooved. Leaves 3-foliolate, usually pubescent on both surfaces; petioles variable in length, 1–4 in.; leaflets small, $\frac{1}{6}$–$\frac{1}{2}$ in. long, all stalked, exceedingly variable in shape, narrow-linear to ovate, acute or obtuse, entire notched or lobed, or even again 3-partite. Peduncles 1-flowered, solitary or 2–4 together in the axils of the leaves, pubescent. Bracteoles in 2 pairs, connate at the base, upper pair much the larger, often foliaceous. Flowers yellowish, small, $\frac{1}{2}$–$\frac{3}{4}$ in. diam., sweet-scented. Sepals 4, linear-oblong, acute or obtuse, silky. Anthers linear. Achenes narrow, margined, silky or nearly glabrous when old, narrowed into rather long plumose tails.—*T. Kirk Students' Fl.* (1899) 4; *Cheesem. Man. N.Z. Fl.* (1906) 5.

North Island: Upper Thames Valley, from Te Aroha southwards, *T. F. C., Petrie!* Taupo, *T. F. C.;* East Cape, *T. Kirk;* probably not uncommon in the interior. South Island: Apparently common throughout, *J. B. Armstrong! Buchanan! T. Kirk!* &c. Sea-level to 3000 ft. September–November.

The brownish colour, slender habit, minute leaflets, and small flowers distinguish this from all other except *C. quadribracteolata*, to which some forms approach far too closely. A variety collected by Mr. Petrie at Tuapeka (Otago) appears to be quite intermediate, and might almost be referred to either species. North Island specimens are usually more slender and have smaller leaflets than the southern ones. Some of Mr. Petrie's Otago specimens are remarkable for their large foliaceous bracteoles, which are linear-spathulate and sometimes $\frac{3}{4}$ in. long.

9. **C. quadribracteolata** *Col. in Trans. N.Z. Inst.* xiv (1882) 329.—Stems and branches very slender, branched, trailing, 1–3 ft. long, glabrous except the very young shoots. Leaves few, trifoliolate; petioles slender, 1–2 in. long; leaflets minute, $\frac{1}{6}$–$\frac{1}{4}$ in. long, usually linear or lanceolate, but varying to linear-oblong, ovate-lanceolate, or triangular-acute, glabrous, entire or one or all 3-lobed. Peduncles solitary or 2–3 together in the axils of the leaves, 1-flowered, usually shorter than the petioles, pubescent; bracteoles 2 or 3 pairs, connate, upper the largest, sheathing at the base, rounded, obtuse. Flowers purplish, sweet-scented, $\frac{1}{4}$–$\frac{3}{4}$ in. diam. Sepals 4, linear or linear-oblong, usually acute, silky. Anthers linear. Achenes small, almost glabrous when fully ripe, narrowed into short plumose tails.—*T. Kirk Students' Fl.* (1899) 5; *Cheesem. Man. N.Z. Fl.* (1906) 6. C. foetida *var.* depauperata *Hook. f. Fl. Nov. Zel.* i (1853) 7; *Handb. N.Z. Fl.* (1864) 2.

North Island: Low grounds in the Hawke's Bay District; Lake Rotoatara, *Colenso!* Petane, *A. Hamilton!* between the Ngaruroro and Tukituki Rivers, *Sturm.*

This can only be separated from the preceding by its smaller size, more slender habit, narrower leaflets, purplish flowers, and narrower sepals. Further investigation will probably prove both to be forms of one variable plant.

2. **MYOSURUS** Linn.
